RESEARCH ON THE INVOLVEMENT OF SOME RISK FACTORS IN BREAST TUMOURS ETIOLOGY. OBSERVATIONS IN THE IASI COUNTY, BETWEEN 2007 AND 2010 (Abstract): **The aim of study** was to assess some risk factors and their involvement in female breast tumours etiology. **Material and methods**. The study was performed on a sample of 67 patients registered with breast tumours, at family phisicians' offices from Iasi, Romania. **Results**. Some risk factors were defined such as: nuliparity (20.8%) and first pregnancy after age 30 (34.3%); fibrous mastopathy in personal history (73.1% of cases with breast cancer) and breast cancer in siblings of first (8.9%) and second grade (11.9%). Relative to lifestyle, sedentary life was remarked in 59.2% of patients; modification of circadian rhythm in 28.3%, and excesive caffeine consumption in 80.9% of cases. **Conclusions**. Further prevention and educational programs on breast tumoural risk factors are needed in Romania, even at female teenage, performed by family physician. **Key words**: MAMARY DYSPLASIA, BREAST CANCER, RISK FACTORS.

Conform datelor statistice recente, boala canceroasă cauzează aproximativ 7,6 milioane decese în fiecare an, la nivel mondial, din care mai mult de 72% apar în țările cu nivel socio-economic scăzut şi mediu şi se prognozează că aceste cifre vor ajunge la 17 milioane în 2030. Cancerul mamar este cea mai frecventă cauză de deces prin cancer, la femei, în Uniunea Europeană (17,2% din total, în anul 2010) (1, 2).

În etiologia tumorilor mamare sunt recunoscuți a fi implicați numeroşi factori de risc, în relație cu diferite aspecte controlabile (stilul de viață, de nutriție, de mediu, tratamente associate pentru diverse comorbidități) sau necontrolabile (vârsta, constelația genetică ereditară), cumulându-se odată cu înaintarea în vârstă (3, 4, 5, 6).

Biroul Regional OMS pentru Europa, susține, de Ziua Mondială a Cancerului, din 4 februarie, faptul că modificări în stilul de viață şi îmbunătățirea metodelor prevenționale şi mijloacelor de screening ar putea preveni peste 40% din cazurile diagnosticate de cancer (1).

MATERIAL ŞI METODĂ

Studiul de tip descriptiv a fost realizat, în perioada 2007-2010, pe un lot de 67 paciente diagnosticate cu formaţiuni tumorale mamare şi înscrise la cabinete individuale de medicină de familie, din Iaşi. Datele au fost culese cu ajutorul unei fişe de anchetă epidemiologică, special concepută, ulterior prelucrate statistic.

REZULTATE ŞI DISCUŢII

1. Distribuţia anuală a cazurilor de tumori mamare, atât maligne (38,8% din total), cât şi benigne (61,2%), arată o tendinţă uşor crescătoare, dar nesemnificativă statistic, cu scăderea numărului de cazuri în anul 2010, fapt constatat şi la nivel mondial şi posibil explicat prin extinderea şi îmbunătăţirea educaţiei pentru sănătate, referitoare la prevenţie şi screening (3, 4, 5) (fig. 1).

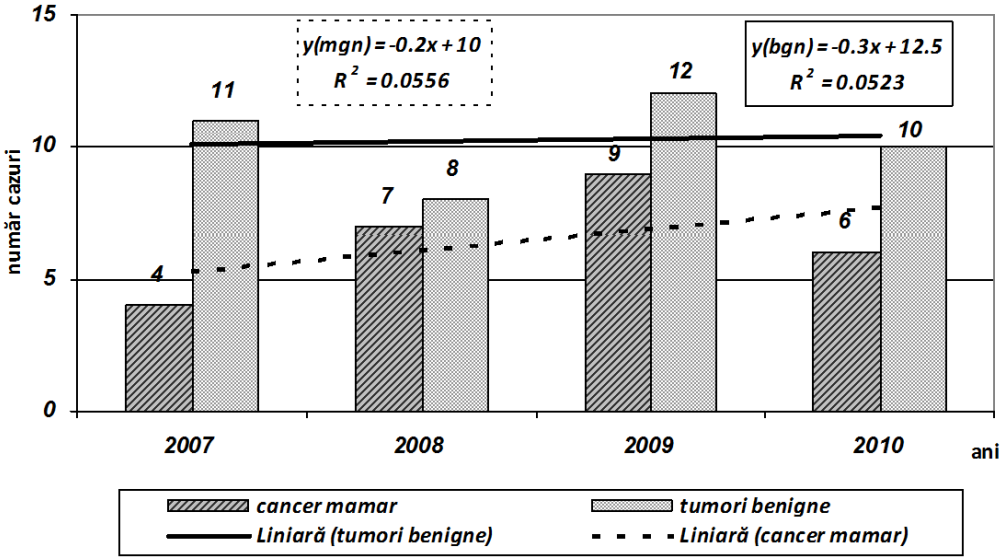

Fig. 1. Repartiţia anuală a numărului de cazuri de tumori mamare

2. Repartiţia pe grupuri de vârstă a arătat faptul că cele mai multe cazuri de tumori benigne au fost înregistrate la grupul 36-45 ani (41,4%), iar de tumori maligne la femeile între 45-65 ani (84,6%, $p>0,05$), grupuri de vârstă care cumulează factorii de risc, atât de tip hormonal, cât şi nutriţional şi comportamental (fig. 2).

3. Distribuţia cumulativă a antecedentelor personale fiziologice a arătat că, în lotul de paciente luat în studiu, menarha precoce (înainte de 12 ani) a fost constatată la 10 paciente (14,9% din total); nuliparitatea la 14 (20,8%) şi prima sarcină dusă la termen după vârsta de 30 ani la 23 femei (34,3%) (iar dintre aceste 37 cazuri, 28 având studii superioare – fapt constatat şi în literatura de specialitate) (3, 8); menopauza instalată după vârsta de 55 ani, în 6 cazuri (27,2% din cele 22 cazuri din grupul de vârstă 55 - ≥ 65 ani) (fig. 3).

4. Distribuţia cumulativă a unor antecedente personale patologice. Mastopatia fibrochistică a fost găsită la 19 paciente diagnosticate cu neoplasm de sân (73,1%); fibromul uterin în 11 cazuri (16,4%); sin-

dromul ovarelor polichistice la 9 femei (13,4%); patologie tiroidiană benignă în 7 cazuri (10,4%). La 14 paciente (20,8%) a fost constatată prezența hiperglicemiei și diabetului zaharat, iar obezitatea cu IMC > 30 kg/m^2 a fost găsită la 12 (17,9%) (fig. 4).

Datele din literatură arată faptul că acești factori de risc, prezentați mai sus, sunt întâlniți în mod frecvent în istoria patologiei tumorale a sânului, la femei cu stilul de viață caracteristic țărilor dezvoltate, în care se include și România (1, 5, 8, 9, 10).

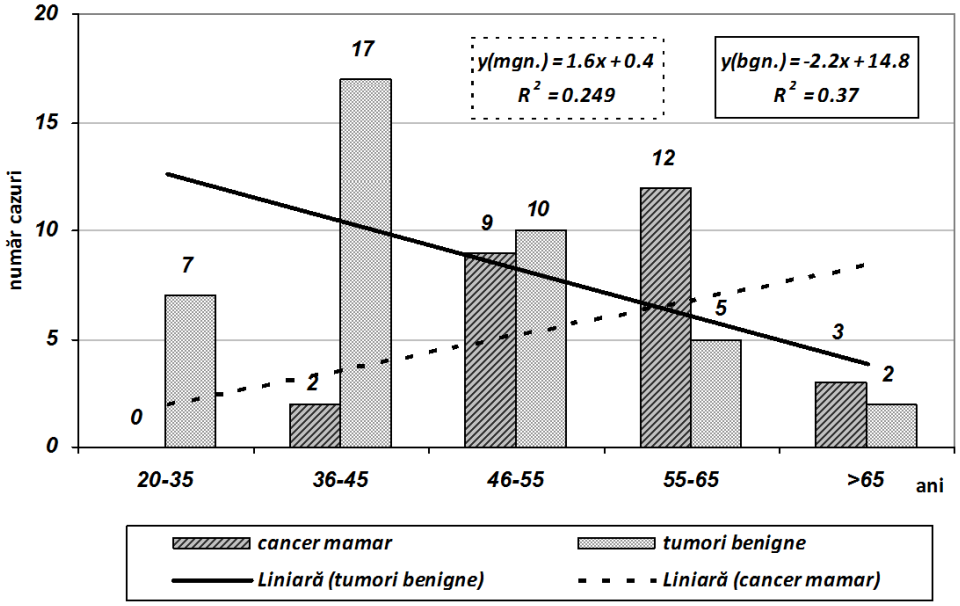

Fig. 2. Repartiția pe grupuri de vârstă

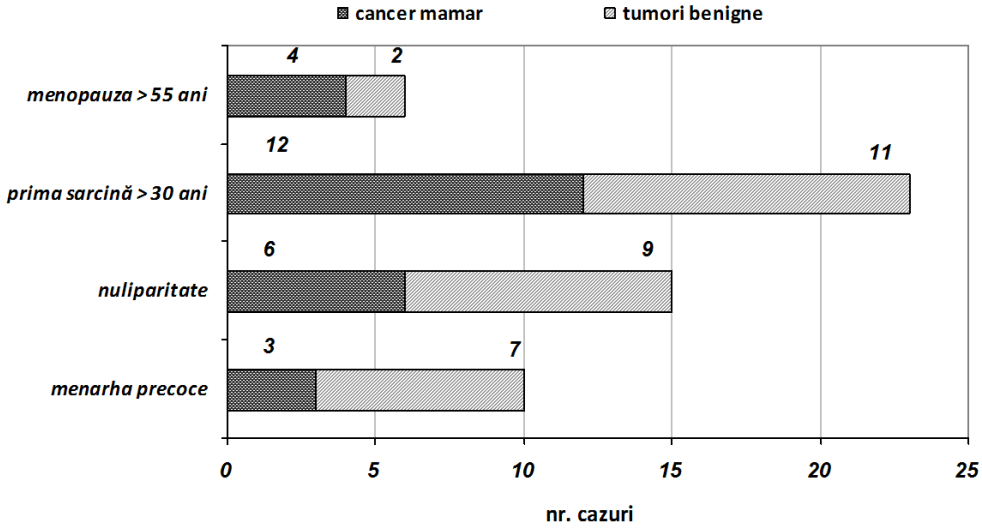

Fig. 3. Repartiția antecedentelor personale fiziologice

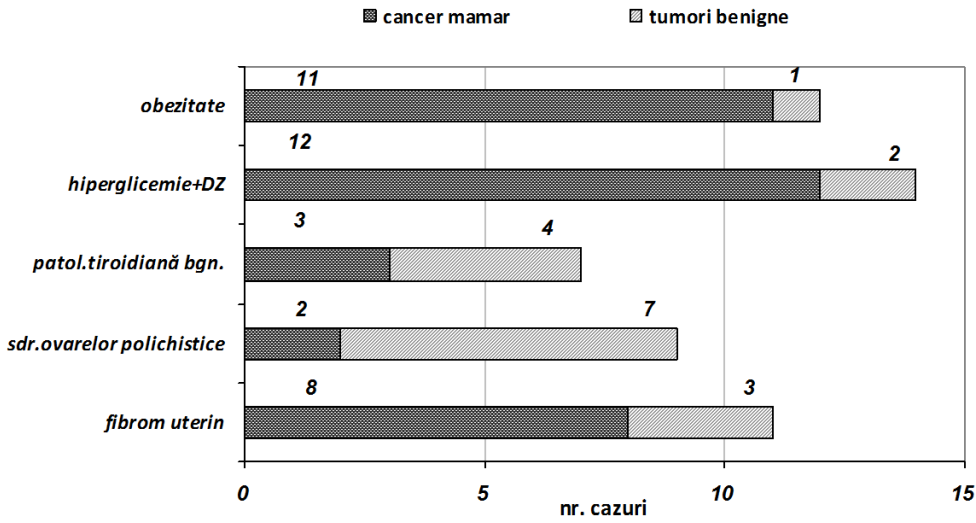

Fig. 4. Repartiția unor antecedente personale patologice

5. Distribuția cumulativă a unor antecedente familiale. Anamnestic, la rude de gradul I, a fost remarcată prezența cancerul de sân în 6 cazuri (8,9%) şi a tumorilor de prostată în 3 (4,4%); tumori cu alte localizări la 12 paciente (17,9%). La rude de gradul al II-lea, s-a constatat existența cancerului mamar în 8 cazuri (11,9%) şi a tumorilor cu alte localizări în 13 cazuri (19,4%) (fig. 5).

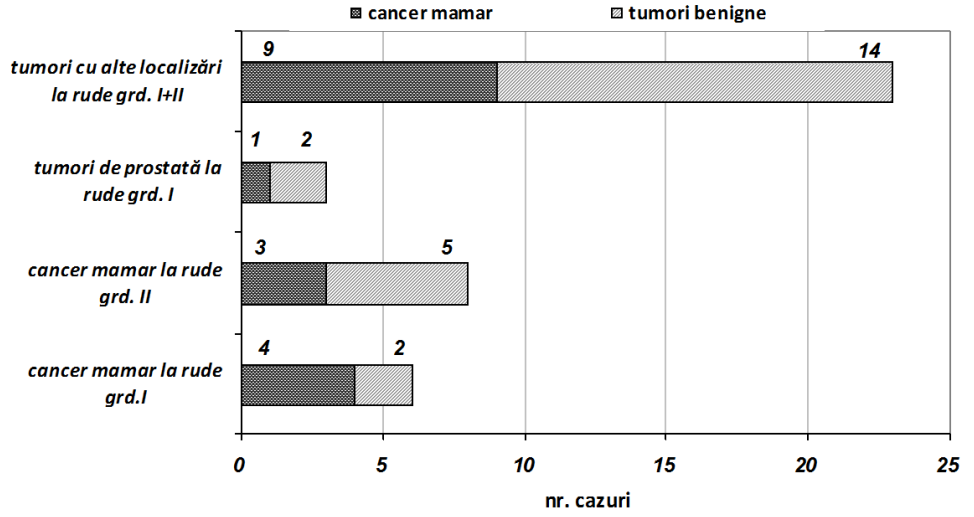

Fig. 5. Repartiția unor antecedente familiale

Aceste date, deşi în valori procentuale ridicate, nu le putem considera semnificative statistic şi de extrapolat, însă ele se calchează pe alte rezultate întâlnite în lite-

ratura de specialitate, referitoare la istoricul familial în cancerul de sân (5, 6, 7).

6. Observații referitoare la stilul de viață şi nutrițional al pacientelor. Tendința la sedentarism (4, 5, 8) a fost afirmată de 39 paciente (58,2%) (fig. 6). Am luat în studiu modificarea ritmului circadian (trezirea frecventă în timpul nopții, lucrul pe timp de noapte sau / şi insomnie), care a fost găsită la 19 femei (28,3%), date asemănătoare cu ale altor studii derulate şi publicate în ultimii ani (11). Deşi un factor de risc controversat (4, 5, 12), consumul crescut de cofeină (> 2 ceşti cafea / zi, timp de > 15 ani) a fost afirmat de 54 paciente (80,6%) (fig. 7).

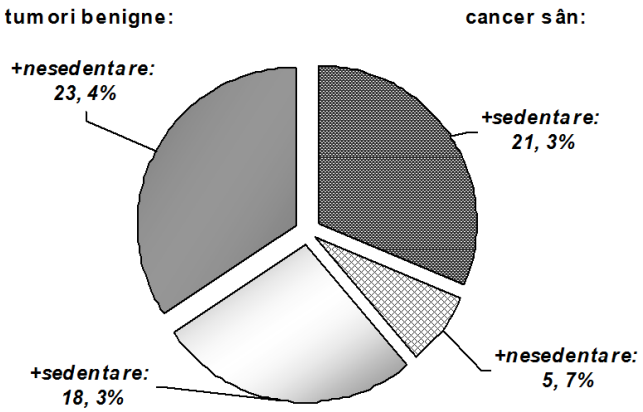

Fig. 6. Sedentare *vs* nesedentare în lotul cu tumori de sân

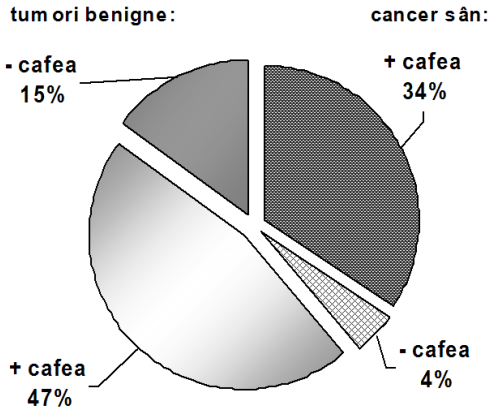

Fig. 7. Consumul de cofeină în lotul cu tumori mamare

CONCLUZII

Studiul descriptiv derulat pe un lot de 67 paciente înscrise pe lista medicului de familie şi diagnosticate cu tumori mamare, în perioada 2007-2010, a arătat faptul că cele mai multe tumori au fost diagnosticate la 45-65 ani, vârste la care se cumulează numeroşi factori de risc instrinseci şi ex-

trinseci, după cum am constatat şi noi, dintre care: nuliparitatea (20,8%) şi prima sarcină dusă la termen după vârsta de 30 ani (34,3%); mastopatia fibrochistică în antecedentele personale (73,1% din cazurile cu neoplasm mamar) şi cancerul mamar la rude de gradul I (8,9%) şi II (11,9%). Referitor la stilul de viaţă, sedentarismul a fost afirmat în 59,2% din cazuri, modificarea ritmului circadian de către 28,3% dintre femei, iar consumul în exces de cofeină, remarcat în 80,9%.

Constatăm faptul că este necesară optimizarea programelor educaționale şi pentru sănătate, referitoare la factorii de risc implicați în apariția tumorilor mamare, prin derularea acestora încă de la vârsta adolescenței feminine, prin cabinetul medicului de familie, dar şi prin cele de medicină şcolară.

1. Catedra de implantologie orală
2. Catedra de ortodonţie şi ortopedie dento-facială

PREPROSTHETIC ORTHODONTIC TREATMENT - RETROSPECTIVE STATISTIC STUDY (Abstract): Orthodontic treatment as a help is the teeth movement made in order to facilitate the odontal,prosthetic and periodontal proceedures which are needed in the dentomaxilar and/or facial reabilitation. The aim of the study was to follow for 5 years which is the percentage of patients who asked for orthodontic treatment in the Orthodontic and Dentofacial Orthopedie Clinic from UMF 'Carol Davila'. We also followed the frequency related to the etiology of the loss of some teeth and also the relationship between the loss of the teeth and periodontal disease. In our country, the number of patients who ask for preprosthetic orthodontic treatment is lower comparing with Western and Northtern Europe, but the percentage is increasing due to the dentists calification. We can conclude by saying that the frequency of losing teeth by cavities is increased by age because all patients from the study group aged 35 and above lost their teeth from cavity etiology and the patients aged 18 and lower had genetic etiology in losing their teeth. **Key words**: ORTHODONTIC TREATMENT, TOOTH DECAY

Tratamentul ortodontic adjunct este considerat a fi acea mişcare a dinţilor realizată pentru facilitarea şi eficientizarea procedurilor odontale, protetice şi parodontale necesare pentru restabilirea funcţiilor aparatului dento-maxilar şi / sau pentru îmbunătăţirea aspectului. De cele mai multe ori, acest tip de tratament ortodontic se adresează adulţilor cu cel puţin o edentaţie parţială. După Proffit, tratamentul ortodontic solicitat de către adulţii mai în vârstă reprezintă sectorul ortodonţiei cu creşterea cea mai rapidă în zilele noastre.

Pierderea unui singur dinte comportă o serie de modificări patologice atât ale dinţilor vecini şi antagonişti, cât şi ale parodonţiului de susţinere, tratamentul aferent fiind unul complex: parodontal, ortodontic şi protetic.

Studiile din literatura de specialitate relevă faptul că un procent de 30% dintre pacienţii adulţi trataţi ortodontic necesită un management terapeutic interdisciplinar, printre care se citează: adiţii de os, inserare implante etc. Cu 18 ani în urmă, în 1988, la Congresul EOS din Londra, Perregaard şi Blixencrone-Mřller au găsit un procent de numai 9% de pacienţi adulţi care s-au prezentat pentru tratament ortodontic preprotetic şi 12% pentru boală parodontală.

Scopul studiului prezent este de a urmări pe o perioadă de 5 ani care este procentul de pacienţi, care se adresează medicului ortodont pentru tratament ortodontic adjunct în Clinica de Ortodonţie şi Ortopedie Dento-facială din cadrul Facultăţii de Medicină Dentară, UMF "Carol Davila", Bucureşti. Se urmăreşte, de asemenea, frec-

venţa în strânsă relaţie cu etiologia edentaţiei anumitor dinţi, precum şi asocierea edentaţiilor cu boala parodontală.

MATERIAL ŞI METODĂ

S-a realizat un studiu retrospectiv prin analizarea a 450 de dosare ortodontice ale pacienţilor (fotografii intraorale şi extraorale, ortopantomograma şi teleradiografia de profil), care au solicitat un tratament ortodontic la Clinica de Ortodonţie şi Ortopedie Dento-facială din cadrul Facultăţii de Medicină Dentară, UMF "Carol Davila", Bucureşti în ultimii 6 ani.

Criteriul de includere în studiu a fost prezenţa cel puţin a unei edentaţii sau anodonţii protezate sau nu, care urmează a fi tratată protetic. Nu s-au luat în considerare cazurile de edentaţii sau anodonţii care au fost tratate doar ortodontic prin închiderea spaţiilor. De asemenea, s-au inclus în cercetare şi dinţii ectopici care au fost extraşi ulterior, fie din cauza poziţiei profunde în os, fie din cauza direcţiei orizontale, urmând ca spaţiul corespunzător să fie păstrat şi protezat.

Pentru fiecare subiect care corespunde criteriilor mai sus menţionate s-au reţinut următoarele date într-un tabel : iniţialele numelui, vârsta, sexul, clasa de malocluzie după Angle, numărul dinţilor absenţi, care sunt dinţii absenţi, etiologia edentaţiei ("C" – carioasă, "E" – ereditară), status parodontal ("Pmc" – parodontopatie marginală

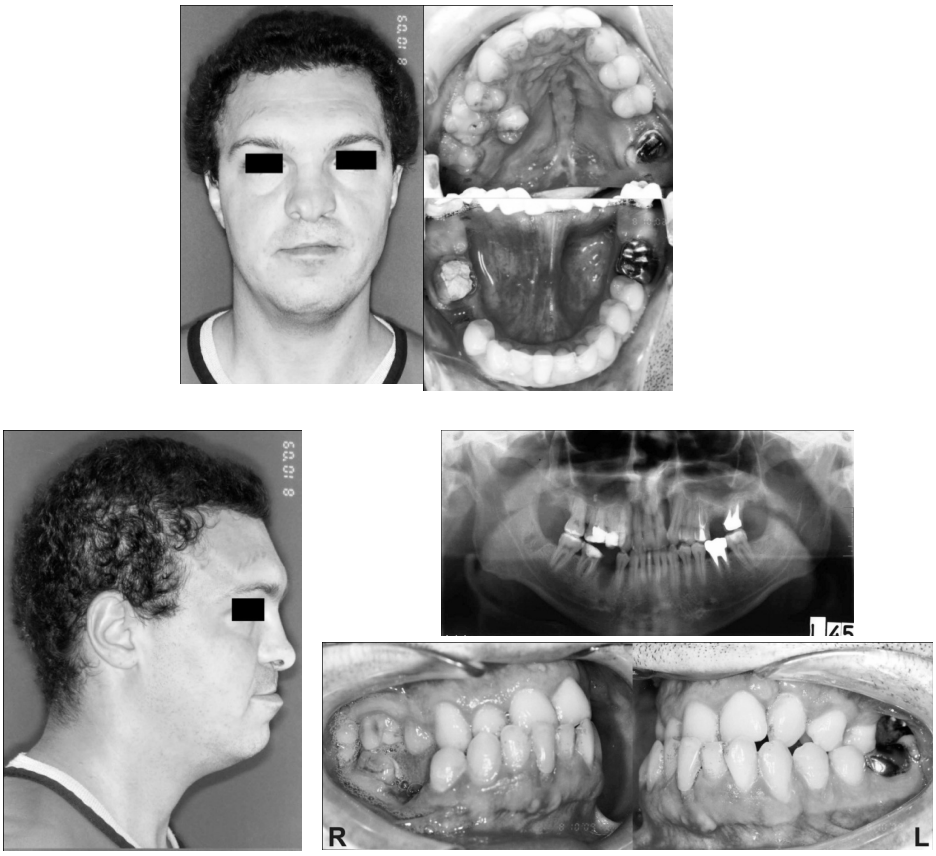

Fig. 1. P.I., 36 ani (din iconografia Dr. Anca Temelcea)

cronică, "Gc" – gingivită cronică) şi s-au găsit următoarele :

Diagnosticul de parodontopatie marginală cronică s-a pus la nivel radiologic pe ortopantomograma, indicând afectarea osoasă în boala parodontală. Diagnosticul de gingivită cronică s-a pus pe aspectul gingiei.

REZULTATE

Dintr-un lot de 450 pacienţi, cu vârsta între 10 şi 36 ani, care s-au prezentat la Clinica de Ortodonţie şi Ortopedie Dento-facială din cadrul Facultăţii de Medicină Dentară, UMF "Carol Davila", pe o perioadă de 6 ani (2005-2010), un număr de 20 de indivizi au fost consideraţi pentru urmarea unui tratament ortodontic adjunct, în vederea protezării prin implante (în mod ideal) ; Procentul corespunzător este de 4,44% pacienţi care necesită tratament ortodontic preprotetic.

Un procent de 35% dintre pacienţii luaţi în studiu au o vârstă sub 18 ani, iar dintre aceştia, toţi au o etiologie carioasă a edentaţiei / edentaţiilor prezente, prin anodonţii, ectopii sau despicături de buză şi palat.

Pacienţii cu vârstă peste 35 ani care necesită tratament ortodontic adjunct, reprezintă un procent de 15% - toţi având o etiologie carioasă a edentaţiei.

Jumătate din lotul investigat este de sex feminin şi cealaltă jumătate de sex masculin.

Împărţirea pacienţilor din lot după clasificarea lui Angle a avut rezultate uimitoare :

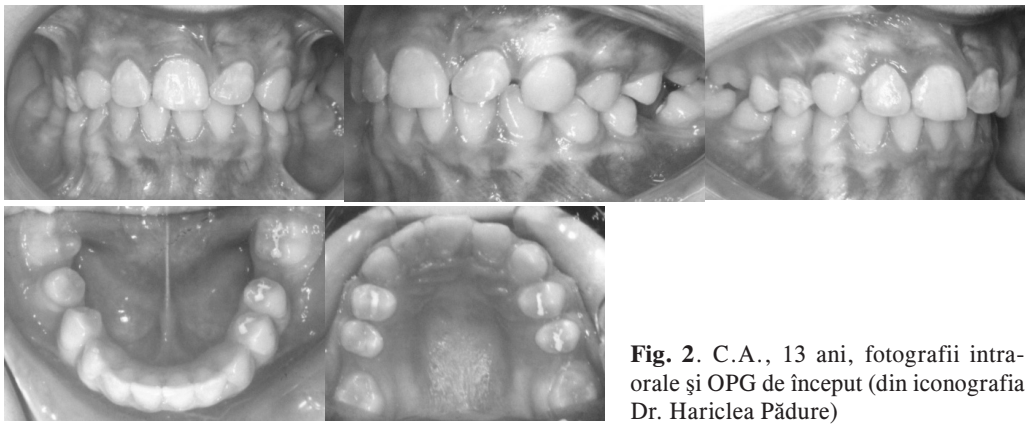

Fig. 2. C.A., 13 ani, fotografii intraorale şi OPG de început (din iconografia Dr. Hariclea Pădure)

40% clasa a III-a, 25% clasa I, 15% clasa II/2, 5% clasa II/1. Procentul crescut de pacienţi clasa a III-a Angle, care necesită tratament preprotetic este la prima vedere surprinzător, având în vedere că malocluziile de clasa a III-a sunt printre cele mai rare în populaţia ţării noastre, dar trebuie avut în vedere faptul că o astfel de anomalie dento--maxilară, netratată, generează în timp traume ocluzale şi forţe nefiziologice care pot duce la edentaţii. Pe de altă parte, trebuie menţionat şi faptul că au fost incluşi în acest studiu pacienţi cu despicături labio-maxilo--palatine cu anodonţii care necesită protezare (figura 1).

Cei mai mulţi prezintă un singur dinte absent, adică 40%, urmând ca 25% să aibă 2 dinţi absenţi, 20% - 4 dinţi absenţi (de regulă toţi cei 4 premolari secunzi), 3 dinţi absenţi – 15%.

Majoritatea dinţilor absenţi care urmează a fi protezaţi sunt premolari, respectiv 33,33%, urmaţi fiind de molarii de şase ani, cu un procent de 22,91%, 8,33% pentru incisivii laterali superiori. Acest rezultat este în concordanţă şi cu procentele apropiate care reprezintă etiologia edentaţiei: 50% pentru etiologia ereditară (anodonţii de pemolari şi incisivi laterali) şi 45% - etiologia carioasă (patologia molarului de şase ani).

În ceea ce priveşte statusul parodontal al pacienţilor care necesită tratament ortodontic preprotetic, s-a găsit un procent de 60% care prezintă o formă de parodontopatie marginală (superficială sau profundă), ceea ce înseamnă că osul alveolar este deja afectat (într-o măsură mai mare, sau mai mică). Gingivita cronică este prezentă la 30% dintre pacienţii investigaţi, iar 10% au fost consideraţi sănătoşi din punct de vedere

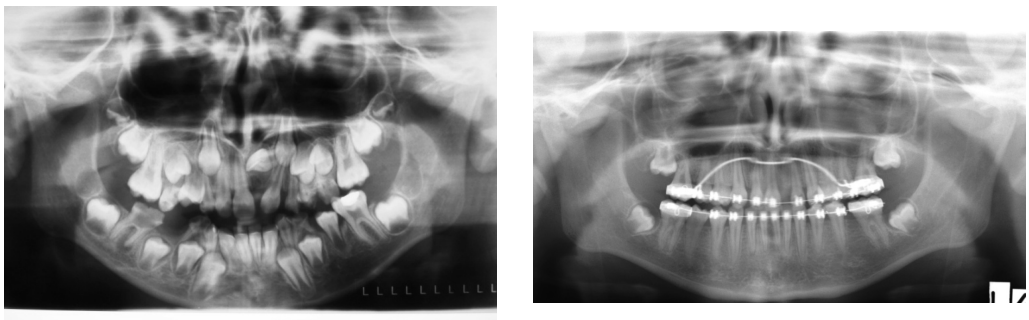

Fig. 3. C.A., OPG de etapă (din iconografia Dr. Hariclea Pădure)

parodontal. Este de remarcat că toţi pacienţii din această ultimă categorie, sunt sub vârsta de 19 ani şi prezintă o etiologie ereditară a edentaţiei.

Cele mai multe cazuri de edentaţii au primit ca indicaţie terapeutică optimă varianta protezării pe implante, în special cazurile cu edentaţii unidentare, cum este şi C.A., în vârstă de 13 ani, cu incluzie orizontală de 21, care a primit indicaţie de extracţie, urmând ca în locul său să fie poziţionat un implant după vârsta de 18 ani (figura 2). După crearea spaţiului necesar unui implant, se va conserva osul alveolar prin mişcarea succesivă a lui 22 între 23 şi 11, precum şi vice versa (figura 3).

DISCUŢII

Procentul destul de mic (4,44%) de pacienţi care necesită tratament ortodontic preprotetic, în comparaţie cu 9% găsit în 1984 în Danemarca, se poate datora atât diferenţei de nivel de trai, cât şi modului de gândire al planului de tratament de către stomatologi, în general.

Procentul egal între femei şi bărbaţi care solicită tratament ortodontic preprotetic este explicabil prin natura acestuia – atât funcţional, cât şi estetic. Astfel că majoritatea pacienţilor care se prezintă pentru tratament ortodontic este reprezentată de sexul feminin – acesta fiind cel mai adesea îngrijorat de aspectul fizic; în cazul tratamentului ortodontic preprotetic, însă, prin prezenţa edentaţiei, apar deja şi disfuncţii masticatorii, pe lângă cele estetice.

În literatura de specialitate au fost citate cazuri multiple de tratament ortodontic preprotetic la un pacient cu o anomalie de clasa a III-a, însă, pe lângă etiologia ereditară şi cea carioasă, Ive a găsit şi o etiologie traumatică pentru edentaţii, în special pentru cele extinse.

Proporţia mare de pacienţi care prezintă o formă de parodontopatie marginală cronică era de aşteptat, luând în considerare procentul ridicat de pacienţi cu anomalii dento-maxilare, întâmplător, procentul fiind identic, 60% (40% clasa a III-a, 15% clasa II/2 şi 5% II/1).

CONCLUZII

La noi în ţară, adresabilitatea pacienţilor la un tratament ortodontic preprotetic este încă scăzută, în comparaţie cu ţările Europei de Vest şi de Nord, dar procentul de astfel de pacienţi este în creştere şi la noi, datorită, în mare parte, formării profesionale a medicului stomatolog generalist.

Se poate concluziona că frecvenţa etiologiei carioase a edentaţiei creşte cu vârsta, având în vedere că toţi pacienţii de peste 35 ani din lotul de studiu au prezentat o etiologie carioasă a edentaţiilor iar cei sub 18 ani, una ereditară.

mecA AND pvl GENES DETECTION IN *STAPHYLOCOCCUS AUREUS* STRAINS ISOLATED FROM LOWER RESPIRATORY TRACT INFECTIONS (Abstract): Although community-acquired *Staphylococcus aureus* pneumonia with highly virulent Panton-Valentine leukocidin (PVL)-positive strains, a severe disease with significant lethality, is rare, especially in adult and adolescent patients, recent reports highlight that these infections are on the rise. On the other hand, methicillin-resistant *S. aureus* (MRSA) is one of the high-risk and potential multi-drug resistant microorganisms. **Objectives**: The aim of this study was to investigate the prevalence of *mecA* and *pvl* genes in *S. aureus* strains isolated from lower respiratory tract infections and to assess the antibiotic resistance profile of these strains. **Material and method**: The antibiotic susceptibility testing was performed by the disk diffusion method according to CLSI recommendations in 32 consecutive non-repeated *S. aureus* strains isolated from sputum specimens and endotracheal aspirates of hospitalized patients over the period from January 2005 to December 2009. Only 20 strains (2008-2009) were tested for the presence of *mecA* and *pvl* genes by real-time PCR and detection with specific fluorescence probes. **Results**: Of the 32 *S. aureus* isolates, 68.7% were MRSA. MRSA strains showed higher resistance rates to gentamicin, tetracycline, rifampicin, fluoroquinolones comparing to the methicillin susceptible ones. Only one strain produced pvl; it was isolated from a 7 year old child with lethal sepsis with pulmonary and meningeal secondary localisations. **Conclusions**: Glicopeptides and linezolid are therapeutic options indicated in the treatment of staphylococcal pneumonia produced either by MRSA strains or pvl positive *S. aureus* strains. **Key words**: *STAPHYLOCOCCUS AUREUS*, RESISTANCE, *mecA*, *pvl*

Staphylococcus aureus este un patogen uman major şi produce o gamă largă de condiţii patologice, de la infecţii cutanate localizate, benigne la infecţii care pun în pericol viaţa pacientului, cum sunt fasciita şi pneumonia necrozantă. Rezistenţa la meticilină a *S. aureus* se datorează achiziţionării genei *mecA* care codifică o proteină de legare a penicilinei cu afinitate scăzută pentru beta-lactamine, PLP2a. Prezenţa acesteia face bacteria rezistentă la toţi reprezentanţii acestei clase de antibiotice (1).

S. aureus rezistent la meticilină (SARM), una din cele mai frecvente cauze ale infecţiilor, este tradiţional recunoscut ca patogen nosocomial. Totuşi, în ultimii ani, epidemiologia sa s-a modificat radical, fiind observat din ce în ce mai frecvent în comunitate. SARM comunitar (SARM-C) poate produce infecţii la indivizi sănătoşi în prealabil, iar

factorii de risc diferă de cei ai achiziţionării SARM nosocomial (SARM-N) (2).

Leucocidina Panton-Valentine (PVL), o leucotoxină producătoare de pori codificată de genele *lukF-PV* şi *lukS-PV*, este în momentul de faţă acceptată ca fiind cel mai important factor de virulenţă al *S. aureus*. PVL a fost asociată epidemiologic cu tulpini comunitare de *S. aureus*, virulente, transmisibile, inclusiv SARM-C (3). PVL a fost corelată cu infecţii specifice cu *S. aureus* cum ar fi infecţii cutanate sau de ţesuturi moi şi pneumonia necrozantă severă la copii şi adulţi tineri anterior sănătoşi, care adeseori urmează după o boală "flu-like". Mortalitatea pneumoniei necrozante este de aproximativ 75% (4, 5). Există mai multe dovezi pentru incriminarea PVL în patogenia pneumoniei necrozante, inclusiv corelaţia epidemiologică puternică cu izolate de *S. aureus* producătoare de PVL (4) şi imunodetecţia PVL în plămân (6), precum şi faptul că doar izolatele de *S. aureus* producătoare de PVL pot reproduce pneumonia necrozantă la modele experimentale (7). Procentul realelor infecţii virale premergătoare este necunoscut, dar coinfecţia cu virusuri respiratorii, inclusiv virusul gripal trebuie investigată.

Totuşi, pacienţii cu pneumonie comunitară cu SARM PVL-pozitive nu au o rată a mortalităţii mai mare decât pacienţii cu pneumonie comunitară cu SASM PVL-pozitive (8).

Pneumonia de ventilaţie produsă de SARM este o complicaţie frecventă în unităţile de terapie intensivă şi se manifestă ca pneumonie cu debut tardiv la pacienţi care au fost intubaţi pentru perioade lungi de timp şi/sau au suferit o bronhoscopie (9). Rezistenţa la meticilină a tulpinilor de *S. aureus* care produc pneumonie de ventilaţie este asociată cu o rată mare a mortalităţii (10, 11). Infecţiile nosocomiale cu SARM duc la creşterea costurilor economice şi de spitalizare.

Tratamentul cu antibiotice al infecţiilor cu SARM-C şi SARM-N poate să difere deoarece SARM-C rămâne adeseori sensibil la antibiotice, altele decât glicopeptide şi antibioticele noi. Mai mult, producerea de toxine, cum este PVL, ar trebui să influenţeze alegerea antibioticului în sensul utilizării unei asocieri cu agenţi antimicrobieni capabili a descreşte producerea de toxină (2).

MATERIAL ŞI METODĂ

Tulpini. Am inclus în studiu 32 de tulpini consecutive de *S. aureus* izolate de la pacienţi (22 bărbaţi, vârsta medie 57 ± 16 ani) diagnosticaţi cu pneumonie. Bacteriemia a fost pusă în evidenţă la 5 dintre aceşti pacienţi. Pacienţii au provenit din diverse localităţi din Nord-Estul Moldovei şi au fost internaţi în Spitalul Clinic de Boli Infecţioase „Sf. Parascheva" Iaşi, între 1.01.2005 şi 31.12.2009.

Testarea sensibilităţii la antibiotice a aces-

tor tulpini a fost făcută prin metoda difuzimetrică (Kirby-Bauer), pe agar Mueller-Hinton, cu discuri de antibiotice Oxoid (Marea Britanie), iar interpretarea testului a fost făcută conform standardelor CLSI (NCCLS) în vigoare la momentul testării. Pentru oxacilină şi vancomicină sensibilitatea tulpinilor a fost testată şi prin detectarea concentraţiei minime inhibitorii (CMI) folosind benzi E-test (bioMérieux, Franţa).

Detectarea genelor *mecA* şi *pvl*. A fost efectuată prin singleplex real-time PCR (RT-PCR) pentru cele 20 tulpini izolate în 2008-2009. Martori pozitivi/negativi au fost *S. aureus* ATCC 25923 (*mecA* absentă, *pvl* prezentă) şi *S. aureus* ATCC 33592 (*mecA* prezentă, *pvl* absentă). Extractele ADN au fost obţinute din cultura în bulion cord-creier a izolatelor clinice şi a martorilor, folosind *GenElute Bacterial Genomic DNA kit* (Sigma Aldrich, Germania). Amplificarea şi detecţia folosind sonde de fluorescenţă s-a făcut cu un aparat Stratagene MX 3005P. Primerii şi sondele utilizate (12) sunt descrise în tabelul I.

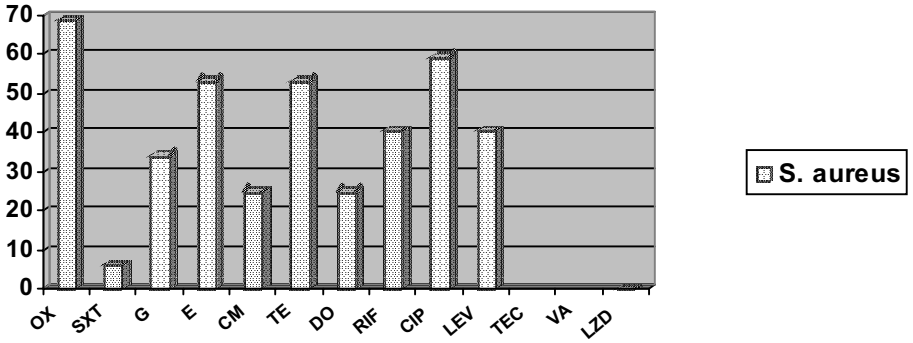
Amestecul de reacţie (20μL) a conţinut : 10 μl 2×*HotStar Taq Master Mix* (Qiagen, SUA), 4 μl amestec de primeri specifici, 0,2 μL sondă de fluorescenţă specifică, 2 μL ADN ţintă şi 3,8 μL apă PCR. Reacţiile au fost efectuate în triplicat, cu următorul profil termic : 7 minute la 95°C, urmate de 40 cicluri de câte 15 secunde la 95°C şi apoi 60 secunde la 60°C.

REZULTATE

Între 1.01.2005 şi 31.12.2009 am izolat 32 tulpini de *S. aureus* de la pacienţi internaţi cu infecţie a tractului respirator inferior în Spitalul Clinic de Boli Infecţioase „Sf. Parascheva" Iaşi, dintre care 22 (68,7%) au fost SARM. 20 dintre tulpinile SARM au fost izolate din infecţii nosocomiale şi 2 din infecţii comunitare.

În figura 1 este prezentată rata rezistenţei la antibiotice a celor 32 tulpini de *S. aureus*. Remarcăm rata înaltă (>50%) de rezistenţă la oxacilină, eritromicină, tetraciclină şi ciprofloxacin. Toate tulpinile rezistente la clindamicină au fost cu rezistenţă inductibilă la acest antibiotic.

Valorile CMI oxacilină au variat între 0,38 μg/mL şi >256 μg/mL, cu CMI(50) = 64 μg/mL şi CMI(90) >256 μg/mL. Pentru cele 20 tulpini izolate între 2008-2009, rezistenţa la oxacilină a fost evaluată şi prin detectarea genei *mecA*. Ea a fost depistată în toate tulpinile cu CMI ≥ 4 μg/mL, stabilind o concordanţă de 100% între cele 2 metode.



OX = oxacilină, SXT = sulfametoxazol&trimetoprim, G = gentamicină, E = eritromicină, CM = clindamicină, TE = tetraciclină, DO = doxiciclină, RIF = rifampicină, CIP = ciprofloxacin, LEV = levofloxacin, TEC = teicoplanină, VA = vancomicină, LZD = linezolid

Fig. 1. Rezistenţa la antibiotice a tulpinilor de *S. aureus* izolate din probe de spută, 2005-2009

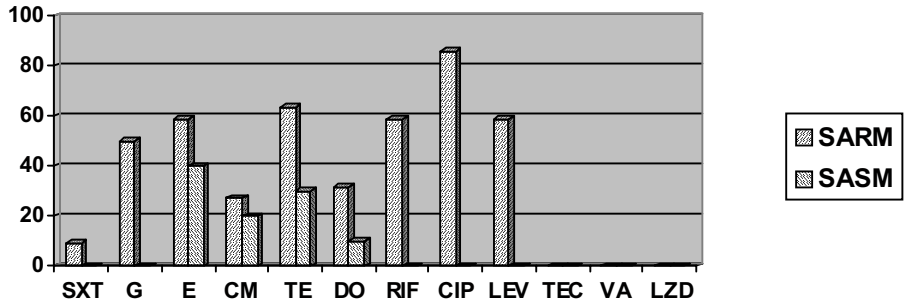


Fig. 2. Rezistenţa la antibiotice a SARM vs. SASM izolate din probe de spută, 2005-2009

Valorile CMI vancomicină au variat între 1-2 μg/mL, cu CMI(50) = 1,5 μg/mL şi CMI(90) = 2 μg/mL.

Remarcăm diferenţe statistic semnificative ($p < 0,05$) între SARM şi SASM privind rata rezistenţei la gentamicină, tetracicline, rifampicină, fluorochinolone (fig. 2).

Am investigat prezenţa genelor *pvl* la cele 20 tulpini *S. aureus* izolate între 2008--2009. Doar una din cele 20 tulpini (5%) a fost producătoare de PVL (fig. 3).

Am remarcat 2 pacienţi între cele 20 cazuri diagnosticate între 2008-2009.

1. Pacienta L.A., 7 ani, fără antecedente patologice sau spitalizări anterioare, care se prezintă în urgenţă cu sindrom meningean apărut la 2 zile după instalarea unui sindrom gripal. Se instituie tratament injectabil cu ampicilină după recoltarea probelor biologice pentru examene microbiologice. Radiografia pulmonară relevă opacităţi diseminate pe ambele arii pulmonare. În sângele periferic s-a obiectivat leucocitoză (11.200/mmc), cu predominenţa PMN, în special elemente imature, cu granulaţii toxice şi trombocitopenie. Din lichidul cefalo-rahidian (LCR), hemocultura şi sputa pacientei se izolează aceeaşi tulpină de *S. aureus*, cu sensibilitate păstrată faţă de toate antibioticele cu excepţia penicilinei; CMI oxacilină

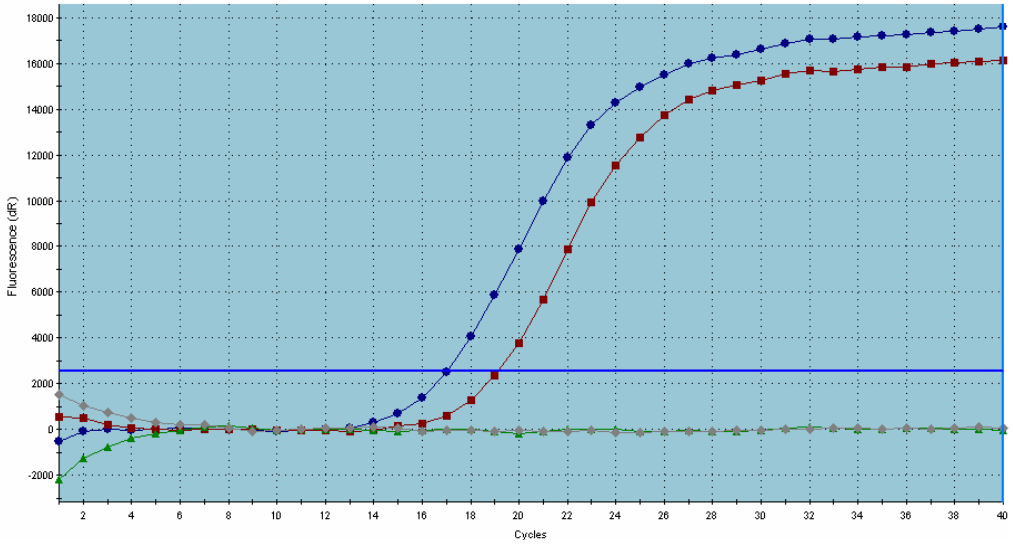

Fig. 3. RT-PCR pentru detectarea genei *pvl* la tulpina 8 (pacient LA), martor pozitiv (*S. aureus* ATCC 25923), martor negativ (*S. aureus* ATCC 33592) şi NTC (*non-template control*)

= 0,125 μg/mL, CMI vancomicină = 1 μg/mL. Retrospectiv, tulpina izolată s-a dovedit a fi producătoare de PVL. Starea generală a pacientei s-a deteriorat rapid, aceasta decedând la mai puţin de 24 ore de la internare prin şoc toxico-septic şi coagulare intravasculară diseminată.

2. Pacienta M.M., 76 ani, imundeprimată (leucemie limfatică cronică), se internează în stare gravă, cu febră şi sindrom meningean. Se instituie terapie cu ceftriaxonă şi ciprofloxacin. Din hemoculturi şi LCR se izolează *S. aureus* cu acelaşi antibiotip – tulpina este rezistentă doar la penicilină şi gentamicină; CMI oxacilină = 0,75 μg/mL, CMI vancomicină = 1,5 μg/mL. Evoluţia pacientei este nefavorabilă, necesitând ventilaţie mecanică. După 5 zile, se izolează din aspiratul traheo-bronşic o tulpină de SARM cu rezistenţă multiplă la antibiotice: gentamicină, eritromicină, clindamicină (rezistenţă inductibilă), teraciclină, rifampicină, ciprofloxacin, levofloxacin; CMI oxacilină >256 μg/ml, CMI vancomicina = 1,5 μg/mL. Pacienta decedează prin insuficienţă multiplă de organ în cadrul sepsisului.

DISCUŢII

Comparativ cu pacienţii cu pneumonie comunitară, cei cu pneumonie nosocomială au fost mai în vârstă (60 ani vârsta medie a pacienţilor cu pneumonie nosocomială vs. 28 ani vârsta medie a pacienţilor cu pneumonie comunitară). Rata mortalităţii a fost similară pentru cele 2 categorii de infecţii (mortalitate 27,2% pentru pneumonii nosocomiale şi, respectiv, 22,2%). SARM este mai frecvent izolat de la pacienţi cu pneumonie nosocomială (100%) decât de la cei cu pneumonie comunitară (25%).

Pneumonia comunitară cu tulpini de *S. aureus* PVL-pozitive este o boală severă. De obicei afectează copilul sau adultul tânăr (vârsta medie 15 ani). Infecţiile cu tulpini PVL-pozitive se asociază mai frecvent cu: temperatură peste 39°C, puls peste 140/minut, hemoptizie, apariţia de exsudat pleural în cursul spitalizării. De regulă leucopenia, simptomele pseudogripale sau gripa cu confirmare de laborator şi hemoptizia sunt factori asociaţi cu decesul (13). În cazul descris de noi infecţia a fost letală, a avut o durată scurtă de la instalarea simptomelor până la deces (48 ore), diseminare sistemică (hemoculturi pozitive), localizări secundare meningeene şi pulmonare, leucocitoză moderată cu polinucleoză cu predominanţa elementelor imature şi granulaţii toxice în sângele periferic. Terapia de primo-intenţie instituită în acest caz nu a fost susţinută de antibiograma tulpinii izolate.

Antibioticele care inhibă producerea PVL ar putea fi mai adecvate pentru tratamentul pneumoniei severe necrozante, prin analogie cu utilizarea lor în sindromul şocului toxic streptococic sau stafilococic (14,15, 16). Într-un studiu al lui Dumitrescu et al. (17), examinând capacitatea *S. aureus* de a elibera PVL în prezenţa antibioticelor, nu a fost detectată PVL dacă *S. aureus* a fost incubat în prezenţa unor concentraţii inhibitoare de antibiotic, pe când concentraţii subinhibitorii de oxacilină au crescut nivelul PVL. Clindamicina, linezolidul şi acidul fusidic au fost inhibitorii, iar vancomicina nu a avut aproape niciun efect. Linezolidul este eficient clinic împotriva *S. aureus* PVL-pozitive (18).

Tulpinile de *S. aureus* izolate din pneumonii în studiul nostru se remarcă prin procentul mare de rezistenţă la oxacilină (68,7%), mult peste rata rezistenţei la oxacilină a tulpinilor de *S. aureus* izolate din infecţiile cu alte localizări (45,7%). 33% dintre tulpinile testate au avut CMI oxacilină >256 μg/ml. De asemenea remarcam procentele mari de rezistenţă la gentamicină, tetracicline, rifampicină, fluorochinolone la tulpinile SARM comparativ cu SASM.

Niciuna din tulpinile testate nu a fost rezistentă la glicopeptide sau linezolid, indicând aceste antibiotice ca alternative excelente

pentru tratamentul infecţiilor cu SARM.

Cazul de pneumonie nosocomială cu SARM descris de noi se remarcă prin achiziţionarea tulpinii infectante în cursul terapiei intraspitaliceşti pentru sepsis cu SASM. Tulpina nosocomială a fost multiplu-rezistentă.

Vârsta înaintată, sexul masculin, dificultăţi la deglutiţie şi inabilitatea de a ingera medicaţia orală sunt factori de risc semnificativi pentru pneumonia asociată îngrijirilor medicale, produsă cel mai frecvent de *S. aureus*, inclusiv SARM, *Pseudomonas aeruginosa* şi bacili gram-negativi intestinali (19).

Deşi tratamentul standard al pneumoniei cu SARM sunt glicopeptidele, linezolidul este considerat o alternativă în special în pneumonia nosocomială. Comparativ cu glicopeptidele, linezolidul atinge niveluri pulmonare mai ridicate, care se pot corela cu eficacitate sporită în tratamentul pneumoniei nosocomiale. Studiile clinice nu susţin însă superioritatea linezolidului faţă de glicopeptide în tratamentul pneumoniei nosocomiale. Deşi a fost obţinută o eradicare microbiologică mai rapidă prin terapie cu linezolid a pneumoniei produse de SARM în secţii de terapie intensivă, totuşi eficacitatea clinică şi rata supravieţuirii au fost similare cu cele obţinute prin terapia cu teicoplanină. Linezolidul are un risc de două ori mai mare de trombocitopenie şi efecte secundare gastrointestinale. Vancomicina şi teicoplanina nu sunt asociate cu un risc mai mare de disfuncţie renală decât linezolidul (20).

CONCLUZII

Tulpinile de *S. aureus* izolate din pneumonii în studiul nostru se remarcă prin procentul mare de rezistenţă la oxacilină (68,7%), mai mare decât procentul SARM izolate din infecţiile cu alte localizări (45,7%).

Pneumonia nosocomială cu *S. aureus* apare mai frecvent la bătrâni, iar pneumonia comunitară cu *S. aureus* producător de PVL apare mai frecvent la tineri anterior sănătoşi.

Glicopeptidele şi linezolidul sunt opţiunile terapeutice indicate în cazul pneumoniei stafilococice, atât cu SARM, cât şi cu *S. aureus* PVL pozitiv.

MULŢUMIRI

Cercetările descrise în acest studiu au fost posibile cu finanţare CNCSIS –UEFISCSU, prin proiectul PNII – IDEI cod ID_1586/2008.

HISTOPATOLOGIC AND IMMUNOHISTOCHEMIC CHANGES IN *HELICOBACTER PYLORI* COLONISED GASTRIC MUCOSA (Abstract): *Helicobacter pylori* (*H. pylori*) colonize gastric mucosa causing both inflammatory changes, premalignant lesions and malignant tumors, including gastric lymphoma and carcinoma. In this study, our propose was to evaluate the histopatological changes corellated with immunohistochemical results demonstrating the types of cellular infiltration and proliferative activity of gastric mucosa infected with *H. pylori*. **Material and method**: Gastric endoscopic examinations was performed in 468 patients with anti-*H. pylori* antibodies and dispeptic phenomena. Snippets harvested endobiopsic stomach were fixed in formalin and processed by paraffine inclusion. Histological sections were stained with hematoxylin-eosine and Giemsa. In 65 cases of endobiopsic fragments (36 deep chronic gastritis with intestinal metaplasia, glandular atrophy and intraepithelial neoplasia and 29 carcinomas) immunohistochemical reactions were performed by applying reagents for evidence of *H. pylori* colonies, of T lymphocytes (CD3) and macrophages (CD68) and Ki-67 reagent for proliferating nuclear antigen labelling. **Results**: Endobiopsic specimen found in all *H. pylori* or by Giemsa staining or by anti-*H. pylori* antibodies when they were in small numbers. Histologically, were diagnosed: 463 superficial and deep chronic gastritis associated with premalignant lesions, 29 carcinomas, 2 non-Hodgkin's lymphoma and an ademathous polyp. Immunohistochemically, inflammatory infiltrate consisted of numerous T lymphocytes, macrophages and lymphoid follicles. Foveolar cell nuclei, in areas of intraepithelial neoplasia and carcinomatous cells were intensely stained with Ki-67, demonstranting increased proliferation. **Conclusions**: In gastric infection with *H. pylori,* inflammatory infiltrat is composed of abundant macrophages and T lymphocytes. Ki-67 was absent or minimal in chronic gastritis, while in areas of intraepithelial neoplasia was positive in both foveolar and coating epithelium. Anti-*H. pylori* antibodies in human serum remains one of the simplest methods to detect *H. pylori,* therefore it plays an important role in practice. Medical eradication of bacteria may cancel inflammatory changes, metaplasia and proliferation of gastric mucosa and thus it prevents the cascade of carcinogenesis. **Key words**: HELICOBACTER PYLORI, CHRONIC GASTRITIS, PROLIFERATION, Ki-67, CARCINOGENESIS

Helicobacter pylori (*H. pylori*) colonizează mucoasa gastrică cu predilecţie în aria antrală (1), determinând leziuni de intensitate variabilă, atât cu caracter inflamator asociat cu leziuni premaligne, cât şi, în timp, apariţia de tumori maligne, ca:

limfomul şi carcinomul gastric (2,3). Luând în considerare prevalenţa mare a infecţiei cu *H. pylori* (peste 80% din populaţie, în ţările în curs de dezvoltare, 50% din persoanele infectate fiind asimptomatice) (4,5, 6), devine importantă investigarea populaţiei în vederea detectării anticorpilor anti-*H. pylori*. În acest studiu ne-am propus evaluarea modificărilor histopatologice în corelaţie cu rezultatele imunohistochimice ce demonstrează tipurile celulare din infiltratele inflamatorii şi activitatea proliferativă ale mucoasei gastrice infectate cu *H. pylori,* ce pregătesc condiţiile de transformare malignă.

MATERIAL ŞI METODĂ

Lotul de studiu a fost constituit din 468 pacienţi cu anticorpi serici anti-*H. pylori,* examinaţi endoscopic cu obţinerea de fragmente endobiopsice multiple din corpul gastric, antru şi din leziunile constatate la acest examen. Fragmentele endobiopsice au fost prelucrate prin metoda de includere la parafină, apoi secţiunile histologice de 5 μm au fost colorate prin tehnici curente (hematoxilin-eozină) şi histochimice (coloraţia Giemsa pentru aprecierea coloniilor de *H. pylori* şi albastru alcian pH 2,5 pentru evidenţierea mucusului acid). Un grup selectat de 65 de pacienţi cu anticorpi serici anti-*H. pylori*, cu gastrită cronică profundă asociată cu leziuni premaligne şi carcinoame gastrice, decelate histopatologic, a fost investigat imunohistochimic (IHC) prin aplicarea de anticorpi monoclonali. Tehnica de colorare imunohistochimică: prelucrarea lamelor s-a efectuat după metoda Complexului Steptavidin-Biotină (sABC) / Horse Radish Peroxidase (HRP). S-au utilizat următorii anticorpi primari:

- anticorpul monoclonal anti CD3 reacţionează cu limfocitele T;
- anticorpul monoclonal anti CD68 reacţionează cu macrofagele şi monocitele; în acest studiu am utilizat clona PG-M1, DAKO a anticorpului anti-CD68, RTU, pentru a evidenţia macrofagele;
- pentru evidenţierea *H. pylori* am folosit anticorpul policlonal anti-*H. pylori* cu diluţie de 1: 20; epiteliul gastric infectat cu *H. pylori* marcat cu anticorpul policlonal anti-*H. pylori* prezintă colorare apicală a membranelor celulare precum şi reacţie pozitivă în lumenul gastric, deasupra epiteliului;
- anticorpul monoclonal anti Ki67 permite monitorizarea directă a proliferării celulare. Antigenul Ki-67 este o proteină nucleară mare (395 kDa) exprimată preponderent în cursul fazelor active ale ciclului celular (G1, S, G2, M) şi absentă în faza G0; în acest studiu am utilizat clona MIB-1, cu diluţie 1:75.

Pentru controlul reacţiilor imunohistochimice am folosit evaluarea controlului pozitiv extern pe secţiuni realizate din ţesuturi în care pozitivitatea pentru un anumit marker era certă cu scopul de a verifica eficienţa reactivilor folosiţi şi corectitudinea tehnicii folosite. Imunoexpresia a fost gradată în raport cu intensitatea reacţiei (0-negativ; 1-slab; 2-moderat; 3-intens) şi extensia colonizării, cu gradele: 1≤10% din celule; 2-25%; 3-25-50%; 4-50-75%; 5≥75%). Evaluarea a fost apreciată în raport cu localizarea în mucoasa gastrică: epiteliul superficial, foveolar, glandular, tumoral.

REZULTATE

Lotul de studiu a cuprins 468 pacienţi cu anticorpi serici anti-*H. pylori şi* examen endoscopic asociat cu endobiopsii gastrice. Lotul a fost constituit din 270 femei şi 198 bărbaţi, cu vârsta medie de 54±5 ani.

Histopatologic, la examenul standard, s-au diagnosticat 436 gastrite cronice, 29 carcinoame gastrice, 2 limfoame non-Hodgkin gastrice şi 1 polip adenomatos cu neoplazie intraepitelială uşoară. Din cele 436 gastrite cronice, s-au constatat 19 gastrite cronice superficiale localizate mai ales în zona corpului gastric, 417 au fost gastrite cronice profunde antrale şi pangastrite. În

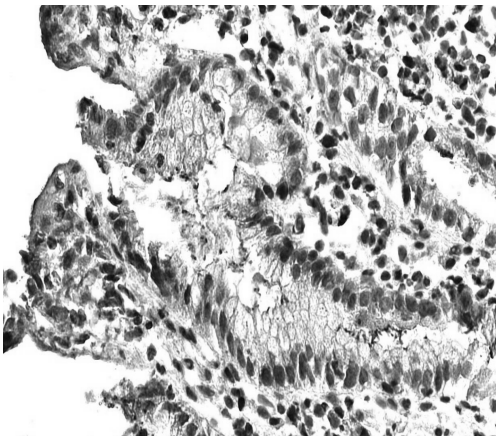

Fig. 1. Evidenţierea *H. pylori* (x20, Ac monoclonali anti-*H. pylori*)

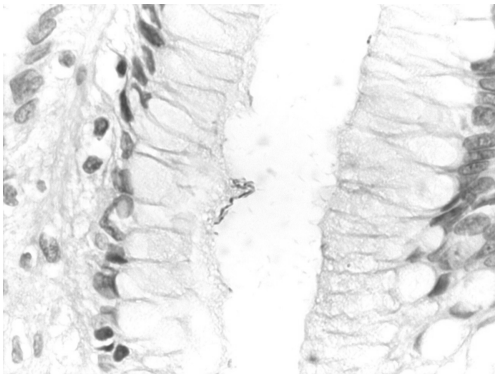

Fig. 2. Evidenţierea *H. pylori* în cazurile cu număr redus de colonii (x40, Ac monoclonali anti-*H. pylori*)

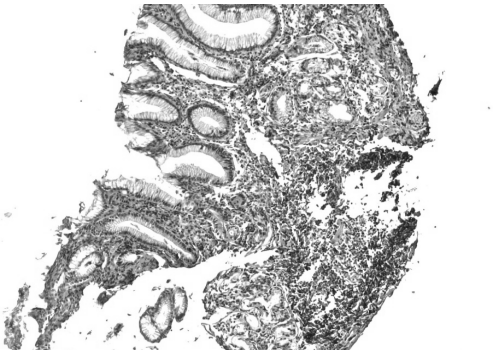

Fig. 3. Foliculi limfoizi în mucoasa gastrică antrală (x10, CD3 pozitiv)

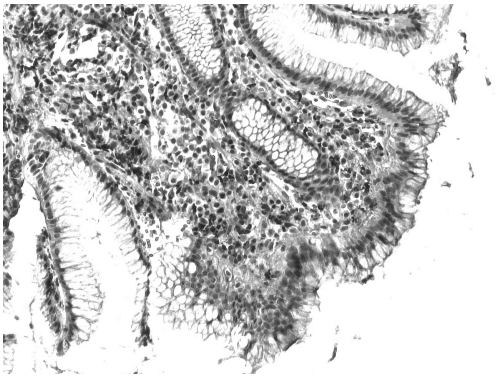

Fig. 4. Macrofage în lamina propria (x40, CD68 pozitiv)

32 cazuri de gastrite cronice profunde antrale, s-a observat asocierea cu leziuni premaligne severe, ca : atrofie glandulară, metaplazie intestinală, neoplazie intraepitelială de grad redus şi de grad înalt. Imunohistochimic, s-a evidenţiat în toate cazurile investigate cu anticorpi anti-*H. pylori,* prezenţa bacteriei, mai ales în ariile cu număr redus, greu decelabil prin coloraţia Giemsa (fig. 1, 2).

În cazurile studiate s-a observat creşterea numărului de limfocite T, asociate cu prezenţa de foliculi limfoizi (fig. 3) şi de macrofage (fig. 4).

Prin aplicarea reactivului Ki-67 s-a constatat colorarea nucleară intensă în celulele

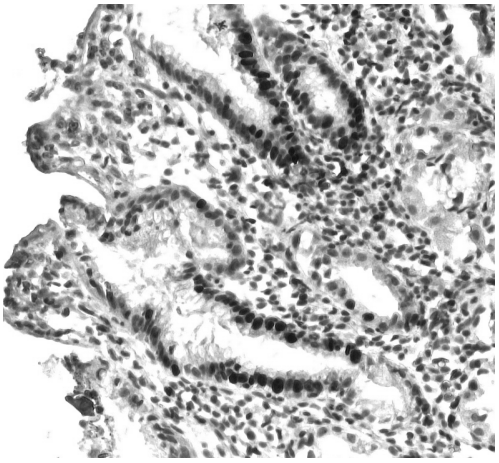

Fig. 5. Gastrită cronică profundă, Ki-67 + în foveole (x10)

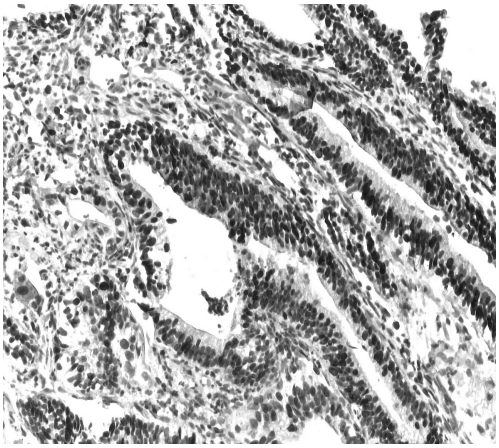

Fig. 6. Gastrită cronică cu displazie severă foveolară, Ki-67+(x20)

epiteliale din foveole (fig. 5) şi din ariile de neoplazie intraepitelială de grad înalt şi în celulele tumorale carcinomatoase (fig. 6).

DISCUŢII

Este acceptat că infecţia *H. pylori* reprezintă un factor de risc pentru apariţia tumorilor maligne gastrice (7,8). Efectele directe ale *H. pylori* sunt relevante pentru inducerea modificărilor inflamatorii (9) ce ulterior determină leziuni premaligne, ca: gastrita atrofică, metaplazia intestinală şi neoplazia intraepitelială de grad redus sau înalt (10,11). Rezultatele studiului nostru demonstrează IHC că inflamaţia determinată de *H. pylori* se manifestă prin creşterea numerică a limfocitelor T, a limfocitelor B, sub formă de foliculi limfoizi şi numeroase macrofage (11,12,13). Astfel, infecţia cu *H. pylori* este asociată cu infiltrat inflamator abundent, cu intensificarea apoptozei şi proliferării celulare (14,15,16).

CONCLUZII

Rezultatele studiului arată că infecţia cu *H. pylori* se manifestă mai ales în antru, sub formă de gastrită cronică profundă, cu hiperplazie micropolipoasă a epiteliului de înveliş şi foveolar, atrofie glandulară asociată cu metaplazie intestinală şi neoplazie intraepitelială (displazie).

O altă concluzie a studiului este că în endobiopsiile gastrice negative pentru *H. pylori* în coloraţia Giemsa este necesară efectuarea reacţiei IHC în scopul evidenţierii bacteriei.

Prezenţa anticorpilor anti-*H. pylori* din serul uman rămâne una din cele mai simple metode de detectare a *H. pylori*; în acest fel, metodele serologice de detectare a *H. pylori* joacă un rol important în practică.

Eradicarea medicală a bacteriei poate să anihileze modificările inflamatorii, metaplazice şi proliferative din mucoasa gastrică şi, astfel, să împiedice cascada carcinogenezei.

NOUTĂŢI

IMPLICAREA GENETICII IN BOLILE AFECTIVE ŞI SUICID

Comportamentul suicidal arată o evidentă concentrare familială şi o concordanţă la gemeni ceea ce sugerează existenţa unei heritabilităţi moderate. Factorii genetici implicaţi în comportamentul suicidal par să se suprapună peste cei implicaţi în bolile afective. Există dovezi incontestabile că atât boala bipolară cât şi cea unipolară sunt influentaţe de genotipul persoanei. Recent, atenţia cercetătorilor a fost atrasă de genele candidate la suicid la pacienţii aflaţi sub tratatment cu antidepresive. Studiile genomice au relevat câteva posibile gene candidat : genele pentru transportorii serotoninei (5-HTT sau SLC6A4), gena pentru triptofan hidroxilaza 1 (TPH1), genele ce codifică factori neurotrofici (BDNF) şi receptorii lor, receptorul pentru neurotrofic tirozin-kinaza tip 2 (NTRK2) sau receptorul adrenergic 2A- (ADRA2A). Tratamentele cu inhibitori selectivi ai recaptării serotoninei sau cu antidepresive triciclice par a creşte, la unii pacienţi, riscul suicidar. La aceşti pacienţi s-a descris existenţa unui polimorfism de tip SNP în gena BDNF. La pacienţii cu risc crescut suicidal în cursul tratamentului cu nortriptyline s-a descris existenţa unui polimorfism SNP în gena pentru receptorul ADRA2A. Aceste date sugerează implicarea sistemului neurotrofic în vulnerabilitatea la suicid. De asemenea s-a observant şi legătura între boala bipolară şi două noi gene : CACNA1C si ANK3. CACNA1C codifică subunitatea alpha-1 a unui canal ionic de calciu voltaj-dependent, în timp ce ANK3 codifică proteina ce leagă acest canal de citoschelet. Polimorfismul de tip SNP în CACNA1C este semnificativ asociat cu boala bipolară, dar şi cu susceptibilitatea crescută la schizofrenie sau depresie unipolară (McGuffin P, Perrouda N, Uhera R. The genetics next term of affective disorder and suicide. *Eur Psych* 2010, 25 (5) : 275-277).

CHROMOGENIC MEDIUM PERFORMACES FOR DETECTION ENTEROBACTERIA PRODUCING EXTENDED-SPECTRUM BETA-LACTAMASES FROM NORTH--EASTERN ROMANIA (Abstract). We evaluated the performances and analyzed practicability of an ESBL-detecting chromogenic agar medium (chromID ESBL, bioMerieux) for the screening of ESBL production. **Material and methods**: We have tested 112 enterobacteria strains, isolated in 2009 year, in North Eastern region of Romania. Each bacterial strain was cultured on a prepared plate chromogenic medium and the results were recorded after incubation at 37°C for 18 to 24 h or, if necessary, for 48 h. We calculated the sensitivities, specificities, and positive and negative predictive values for this medium, using as gold standard ceftzidime or cefotaxime and clavulanate combination disks on Iso-Sensitest agar. *K. pneumoniae* ATCC 700603 and *E. coli* ATCC 25922 were used as the positive and negative control for ESBL production, respectively. **Results**: For all tested strains, the chromID ESBL agar showed a high sensitivity (97%), but a low specificity (66%). The positive and negative predictive values were 98% and 57%, respectively. The chromID ESBL had false-positive results for 2 confirmed ESBL-positive strains. **Conclusion**: The very good sensitivity of the chromID ESBL agar ESBL detection represent a convenient method for the recovery and identification of ESBL-producing enterobacteria. **Key words**: CHROMOGENIC MEDIUM, ENTEROBACTERIA, EXTENDED-SPECTRUM BETA-LACTAMASES

OPTIMIZATION OF THE SYNTHESIS OF SOME NEW THIAZOLIDINE-4-ONE DERIVATIVES WITH XANTHINE SCAFFOLD

OPTIMIZATION OF THE SYNTHESIS OF SOME NEW THIAZOLIDINE-4-ONE DERIVATIVES WITH XANTHINE SCAFFOLD (Abstract): In the last time many researchers were focused on synthesis of new compounds with thiazolidine-4-one scaffold based on the important biological effects of this heterocycle. **Aim:** The aim of this study was to optimize the synthesis of some new thiazolidine-4-one derivatives with xanthine scaffold in order to obtain high yields and advanced purity. **Material and methods:** The synthesis was based on a cyclization reaction between various hydrazones and thioglycolic acid. The optimization was performed for 2-(4-methylphenyl)-3-[(1,3-dimethylxanthin-7-yl)acetamido]thiazolidine-4-one (**b**) by varying different parameters such as molar ratio between reagents, solvent, catalyst, temperature, time of reaction and type of method. There were used ten chemistry procedures for detecting the desired compound and other ones for establishing the optimal conditions. The optimized method was also applied for other thiazolidine-4-one derivatives with xanthine structure. **Results:** The most favorable parameters for optimal synthesis were established as follow: an excess of 20 equivalents of thioglycolic acid to 1 equivalent of hydrazone, freshly distilled toluene as solvent, temperature of 120 °C and reflux for 18 hours. The time and temperature of reaction proved to have a key role for increased yield. **Conclusions:** The optimal conditions of reaction were established in order to obtain new thiazolidine-4-one derivatives in high yields and increased purity. **Keywords:** THIAZOLIDINE-4-ONE, XANTHINE, OPTIMIZATION, SYNTHESIS.

In the last period, the interest of many researchers was directed towards the study of thiazolidine-4-one derivatives due to the intense and important biological activity proved by this heterocycle (1). The studies proved for this scaffold many biological effects, such as antidiabetic, antioxidant, anti-inflammatory, anticancer, antimicrobial, antiviral, anticonvulsant or antihypertensive (2).

This heterocycle is usually found in the structure of synthetic compounds, but also it was identified in natural compounds, such as actithiazic acid (acidomycin) which was isolated from *Streptomyces* strains and proved an intense and specific action on

Mycobacterium tuberculosis (3).

In the literature (1) different methods for the synthesis of thiazolidine-4-one derivatives are described. The most used pathway involves three components: an amine, a carbonylic compound (aldehyde or cetone) and thioglycolic acid and it can be performed in one pot (fig. 1) or two steps (fig. 2).

When the synthesis is performed in two steps, the first reaction is based on the condensation between the amine and carbonyl compounds, resulting the corresponding imine, which, in the next step, it will be cyclized in the presence of thioglycolic acid (fig. 2). In order to apply this method to different thiazolidine-4-one scaffolds, different parameters were varied by the researchers, such as: time and temperature of reaction, solvent (dry toluene, benzene, dioxane, dry tetrahydrofuran, ethanol, dimethylformamide, polypropylene glycol (4)), catalyst (silica oxychloride (5), zinc chloride, N,N'-dicyclohexyl carbodiimide (6), 1-ethyl-3-(3-dimethylamino propyl) carbodiimide,N,N-di-isopropyl-ethylamine (7), N,N,N′,N′-tetramethyl-O-(1H-benzotriazol-1-yl)uranium-hexafluoro-phosphate(8)), water extraction system (Dean Stark apparatus), pH (sodium acetate/acetic acid buffer (9)), methods based on "green chemistry" (ultrasounds, molecular sieves).

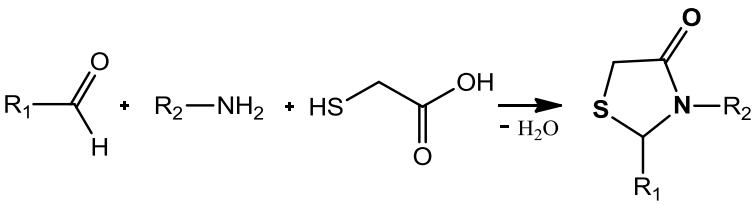

Fig. 1. One pot synthesis for thiazolidine-4-one derivatives.

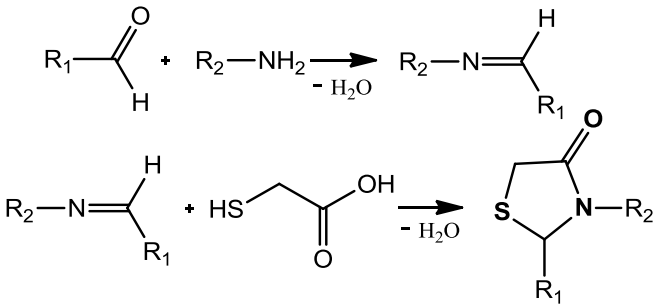

Fig. 2. Synthesis in two steps for thiazolidine-4-one derivatives.

The main objective of this study was the optimization of the synthesis of some new thiazolidine-4-one derivatives with xanthine scaffold, in view of identifying the optimal conditions of reaction (molecular ratio between reagents, time, temperature, solvent, catalyst etc.).

MATERIAL AND METHODS

Reagents. N-(4-Methylbenzylidene)-2-(1,3-dimethylxanthin-7-yl)acethydrazide synthetized in our previous paper (10), thioglycolic acid, organic solvents (freshly distilled toluene and tetrahydrofuran, dimethylformamide - *p.a.* quality), zinc chlo-

ride, 1-ethyl-3-(3-dimethylamino propyl) carbodiimide and molecular sieves were purchased from Sigma Aldrich Company. All reagents and solvents were used without previous purification. Thin Layer Chromatography (TLC) Silica gel 60 F_{254} plates produced by Merck Company and Proton Nuclear Magnetic Resonance (^{1}H-NMR) spectra were used for monitoring the reactions and detecting the resulted compounds. The spectra were obtained in dimethyl sulfoxide deuterated (DMSO-d_6) and chloroform deuterated ($CDCl_3$), both produced by Sigma Aldrich Company. Microwave irradiation was carried out in sealed 2–20 mL vessels placed in a Biotage Initiator system, using a standard absorbance level (300 W maximum power).

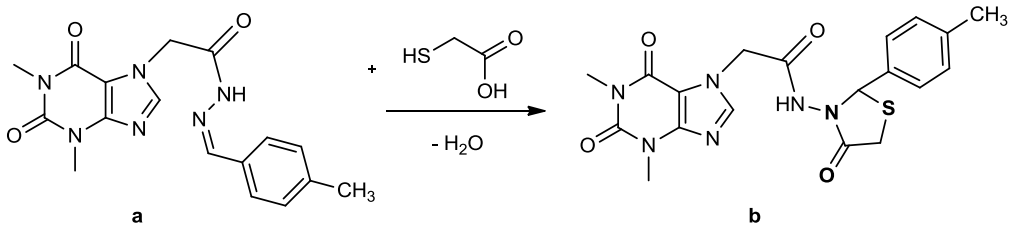

Fig. 3. Synthesis of 2-(4-methylphenyl)-3-[(1,3-dimethylxanthin-7-yl) acetamido]thiazolidine-4-one (**b**).

Chemistry. 2-(4-Methylphenyl)-3-[(1,3-dimethylxanthin-7-yl)acetamido]thiazolidine-4-one (**b**) was obtained based on reaction between N-(4-methylbenzylidene)-2-(1,3-dimethylxanthin-7-yl)acethydrazide (**a**) and thioglycolic acid (fig. 3). The synthesis was performed by optimization of different procedures and methods described in the literature for cyclization between various hydrazones and thioglycolic acid.

For the optimization of the chemistry procedure different parameters were varied: molar ratio between the reagents (1:1; 1:1.55; 1:2; 1:10; 1:15.2; 1:20; 1:24; 1:25.75; 1:27.3), solvent (without solvent (11), dry toluene, dimethylformamide - DMFA, dry tetrahydrofuran - THF), temperature (room temperature - 20ºC, 70ºC, 100ºC, 120ºC, 130ºC, 140ºC, 153ºC, 160ºC, 180ºC), time (between 30 min and 62 hours), catalyst (zinc chloride, 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide), type of method (classic or microwaves).

The reactions were monitored by TLC using different eluent systems: dichloromethane: methanol (9:1; 9.6:0.4; 9.8:0.2), dichloromethane: acetone (7:3), ethyl acetate, ethyl acetate: acetone (7:3). The structure of the compound **b** was proved by NMR spectra.

RESULTS AND DISCUSSION

Chemistry

By varying different synthesis parameters: ratio between reagents, catalyst, solvent, temperature and time of reaction and the applied method (classic or microwave), 10 chemistry procedures were developed (tab. I). Freshly distilled toluene proved to be the most favorable solvent in synthesis of compound **b**. Using this solvent, associated with a ratio between compound **a** and thioglycolic acid of 1 eq.:1.55 eq., in microwave for 40 min, at a temperature of 160 ºC, the condensation reaction was carried out successfully and compound **b** was

detected by NMR spectra.

In the next step the procedure established for synthesis of compound **b** was optimized in order to obtain the compound in high yields and high-grade purity. The experimented conditions are presented in tab II. It was observed that, as described in our previous paper (10), the highest yield (52 %) was obtained after the reaction between 1 eq. of hydrazone **a** and 20 eq. of thioglycolic acid, at a temperature of 120 ºC, for 18 hours, using freshly distilled toluene as solvent.

10.	1 eq.	25 eq.	120	18 h	classic	50%

AT= thioglycolic acid; T (ºC) = temperature; η (%) = yield; MW = microwave; nd = nondetected

The results showed also that the microwave method was not favorable for the synthesis of derivative **b**, the calculated yield being less than 11%. On the other hand for classic method was observed that the increasing of the temperature was associated with the degradation of the compound, the yield being less than 5%. Referring to the time of reaction, the results proved that a lower time than 18 hours was not enough for a total synthesis.

The developed procedure was applied for the synthesis of other thiazolidine-4-one derivatives with xanthine scaffold as described in our previous paper (10).

CONCLUSIONS

In this study, the synthesis of some new thiazolidine-4-one derivatives with xanthine scaffold was developed by optimization of the reaction between N-(4-methylbenzylidene)-2-(1,3-dimethylxanthin-7-yl)acethydrazide (**a**) and thioglycolic acid in order to obtain 2-(4-methylphenyl)-3-[(1,3-dimethylxanthin-7-yl) acetamido]thiazolidine-4-one (**b**) in high yield and an increased purity. The optimization was performed by varying different reaction parameters such as: molar ratio between reagents, time and temperature of reaction, solvent, catalyst and type of method.

THE DIAGNOSTIC CONCORDANCE OF WHOLE SLIDE IMAGING AND LIGHT MICROSCOPY A SYSTEMATIC REVIEW

Traditionally, light microscopy (LM) has been the reference method used in anatomic pathology in the diagnosis of many diseases. However, advances in digital imaging hardware and software have led to the development of whole slide imaging (WSI) devices. These devices allow the digital capture, analysis, storage, sharing, and viewing of whole slide pathology images. Digital pathology evolved as a practical technology in the 1980s with the development of ‘‘telepathology’’ technology. Initially, telepathology existed in 2 forms: static-image telepathology and dynamic robotic telepathology. Static-image telepathology involved the transmission of preselected regions of microscopy images. Dynamic robotic telepathology enabled realtime image alterations by granting a remote user control of the microscope. Since these 2 initial telepathology technologies, more than 12 types of telepathology systems have evolved. Whole slide imaging is the latest technology used in digital pathology (Goacher E, Randell R, Williams B, Treanor D. The Diagnostic Concordance of Whole Slide Imaging and Light Microscopy a Systematic Review. *Arch Pathol Lab Med.* 2017; 141:151–161).

MOTIVATION, STRESS AND SATISFACTION AMONG MEDICAL STUDENTS (Abstract): **The aim** of the study was to identify the relationship between the strength of motivation of medical students, the symptoms they experience, the thoughts of dropping out and the satisfaction with the academic results obtained during their last exam session. The relationship between depression and physical symptoms was also explored. **Material and methods**: A number of 91 students from 4th year of study were included in the survey. Depression and the strength of motivation were measured using *Beck Depression Inventory* and *Strength of Motivation for Medical School.* The obtained data have been processed using SPSS 14 statistical software. **Results**: A positive correlation between the strength of motivation and physical symptoms was identified, meaning that a higher motivation is associated with a higher number of symptoms experienced by students in stressful moments ($r=0.33$, $p=0.01$). Also, women present a higher level of the strength of motivation compared to men [$t(89)=0.47$; $p=0.004$, $p < 0.05$]. A statistically significant difference [$t(89)=0.98$; $p=0.009$, $p < 0.05$] between the average strength of motivation in students who thought about dropping out ($M=53.03$) and in students who never thought about leaving medical school ($M=58.45$) was also identified. Perceived depression was also found to predict the number of symptoms felt by students during stressful times. **Conclusions**: Students that are mostly motivated in medical school also get stressed the most because they want to have good results. **Keywords:** MEDICAL STUDENTS, STRESS, DEPRESSION, MOTIVATION, ACADEMIC SATISFACTION.

The stress experienced by medical students during their academic years was subject of many researches (1, 2, 3). Medical studies doubled by clinical practice and working with human being determine a high level of stress during academic years (4). These factors may affect the psychological and somatic well-being and their academic performance (5, 6).

The strength of motivation could be described as the amount of effort, invested time and sacrifices people would make in order to learn something (7, 8, 9). When battling against stress, the strength of motivation could be an important factor that would help medical students to find a way to cope with it. It has been found that intrinsic motivation leads to better academic performance than extrinsic motivation (10). Luo Lu has also proven in a study that the

interaction between stressors such as work demands and extrinsic motivation could predict physical symptoms and anxiety (11). Not having a high strength of motivation was also shown to be linked to higher levels of stress and a lower academic performance (12, 13). Also, literature states that there is a gender difference regarding the strength of motivation, meaning that women have a higher strength of motivation than men (14).

Due to the increased stress and demands that are placed on medical students, their life satisfaction is affected. It has been found that life satisfaction decreased during medical school, even though students start with the same level of satisfaction in the first year as the students from other universities (15). Another study shows that students of first years were more optimistic regarding their future profession compared to the students from later years of study, thinking that they will work in the medical field (16).

The fact that life satisfaction is decreasing overtime could also be a warning sign for student dropout. Studies show that dropout may be associated with motivation to study medicine, commitment and resilience, besides the institution factors, gender or age (17). In this way, without the incentives of having a high strength of motivation, being resilient in the face of stressors and finding ways to cope with stress, student dropout could increase significantly.

Stress has also many times been linked to depression (1, 18, 19). Depression affects medical students more than it affects the general population (1, 20, 21), possibly because of high demands in medical school, stressors and few coping mechanisms that students find available. The depressive symptoms may have serious consequences on the way students perceive their competencies and their professional future, causing them to dropout or even have suicidal thoughts (1), especially during their 4th year of study (22) or causing somatic problems (23).

The aim of the study is to identify the relationship between the strength of motivation, the symptoms medical students experience during stressful times, the thoughts of dropping out and the satisfaction with the academic results obtained during their last session of exams. Also, we explored the link between depression and physical symptoms, trying to see whether the mental and somatic health is connected during stressful times in medical students. Through observing the relationship between these variables we could begin to have a better understanding of the medical students' lives and try to find strategies in order to improve their health and well-being.

MATERIAL AND METHODS

The lot of participants to our study consists of 91 students from 4th year of study from the University of Medicine and Pharmacy "Grigore T. Popa" Iasi" (74 women and 17 men). The age was 23.16 ±1.157 years (with a minimum of 22 and a maximum of 32 years)

The level of depression was measured using *Beck Depression Inventory* (24) which has 21 questions and the answers are given on a four-point scale. The Cronbach alpha coefficient was 0.93 in college student samples in literature and the Cronbach alpha was 0.87 in our study, showing good internal consistency.

The motivation was evaluated using the *Strength of Motivation for Medical School* (SMMS) (7). The Cronbach alpha in the literature for this scale is 0.79 and, in our study, the internal consistency was 0.83.

Socio-demographic data like age, sex, illness, the type of family of origin, the presence of a chronic disease among the members of the family, the living conditions and academic results (the number of credits obtained during the previous year) were also considered.

To evaluate the physical and psychological symptoms that students feel during stressful times we created a multiple answer question that consists of a list with 35 common symptoms. One of the items referred to the tendency to leave medical school. Contentment with the results obtained in the previous session of finals was also assessed on a five point Likert scale.

The obtained data have been processed using SPSS 14 statistical software.

RESULTS

Socio-demographic and academic data

A number of 19 students come from a rural area, and 72 students come from urban areas. Concerning their current accommodation, 25 students state they are living in the dorm, 31 (34.06%) are living in a rented apartment, 29 (31.86%) are living with their parents and 6 students (6.59%) are living alone. Regarding the relationship between parents, a number of 8 students said that their parents are divorced, the rest of the subjects declaring that their parents are married.

A number of 8 students (8.79%) declared they are chronically ill. Also, concerning the presence of a chronic disease within the family of origin, 30 students (32.96 %) said that they have family members suffering from a chronic disease, while 61 students (77.04%) said they don't have chronic disease among the members of their families.

Concerning the number of academic credits students had in their previous year of study, 2 (2.19%) scored lower than 400, 26 (28.57%) scored between 400 and 500, 43 (47.25%) scored between 500 and 550 and 9 (9.89%) scored between 550 and 600, while 11 (12.08%) didn't state the number of credits obtained, leaving the question unanswered.

Correlational statistics

Strength of motivation

The research explored the relationship between the strength of motivation and physical and psychological symptoms in times of stress, thoughts of dropping out and satisfaction with the academic results obtained.

We wanted to see whether the strength of the motivation of medical students is associated with the number of symptoms checked by the students as being present during stressful times. We found that the motivation correlates with the number of symptoms ($r=0.33$, $p=0.01$). The correlation coefficient demonstrates a moderate strength of the relationship and the correlation is positive, showing that a higher motivation is associated with a higher number of symptoms experienced by students in stressful moments.

Regarding the relationship between the strength of motivation and the contentment with results obtained during the last finals session, we found that the level of motivation correlates with the satisfaction with results ($r=0.22$, $p < 0.05$). The correlation coefficient demonstrates a weak, but significant relationship between the two variables, showing that a higher motivation is associated with a greater satisfaction with results obtained.

Stressors and depression

In the second part of the study we wanted to see whether the perceived depression would be able to predict the number of

symptoms checked by students during stressful times. A significant regression equation was found [F (1.89) =18.75, $p < 0.01$], with an R square=0.174.

Comparative statistics

We compared the strength of motivation considering the existence of thoughts regarding interrupting or abandoning the medical studies. A statistically significant difference was obtained [t(89)=0.98; p=0.009, $p < 0.05$] between the average strength of motivation in students who thought about dropping out (M 53.03) and in students who never thought about leaving medical school (M=58.45).

The sex difference on the strength of motivation was also measured. We found a statistically significant difference [t(89) =0.47; p=0.004, $p < 0.05$] between the average strength of motivation of men (M=50.47) and of women (M=57.86), meaning that women present a higher strength of motivation compared to men.

DISCUSSION

Stress is affecting daily activities and has a great impact on the psychological and physical well-being. It also determines how people are reacting in common situations and is closely linked to the level of performance (1, 25). Researches proved that in some jobs, especially in the medical profession, a high rate of burnout is associated with a high level of depression and suicidal thoughts (22).

We found that the strength of motivation is correlated with the number of physical and psychological symptoms felt, meaning that the higher the students' motivation, the greater the number of symptoms shown. When the students act without being satisfied about their work, they are more stressed comparing to the colleagues who are more pleased about their academic work. Our results show that students with a high strength of motivation are more stressed because they want to be overachievers, train well for their future profession and, when they feel they aren't at their best compared to the image they created for themselves, they could feel emotionally and physically exhausted, thus experiencing more symptoms than a student with a lesser motivation, one that isn't so preoccupied with the studies and with results.

The correlation between motivation and the contentment with results from the previous exam session shows that students with a higher motivation are also the ones that are more satisfied with their results, demonstrating that motivation is connected to greater academic performance, finding that is consistent with other researches (26, 27).

The strength of motivation varied significantly in students who have thought about dropping out and in students who haven't had such thoughts, meaning that the students that didn't see quitting medical school as an option had a higher motivation than the others. Literature has stated that one important risk factor for student dropout is motivation, besides scores obtained in high school and parents' education (28). Stress is very high and constant in medical school and, if the motivation of students isn't strong enough in order to help them efficiently deal with problems, thoughts about dropping out appear.

A difference in the strength of motivation was also found in men and women, showing that women have a significantly higher motivation than men. The fact that female medical students seem to have a higher strength of motivation and motivation quality than men has also been stated in literature (29).

Depression and stress have been linked

in numerous times in literature (30, 31, 32). We found that the level of depression in medical students was able to predict a higher level of somatic symptoms during stressful times. This is an issue that needs to be addressed in order to contribute to the health and well-being of future doctors, given the fact that the stress in medical school is constant and is followed by stress after graduation, during their entire profession. Also, the medical profession is associated with a higher rate of burnout, especially for professionals working in emergency departments, surgery, obstetrics and gynecology and anesthesiology clinics (33) so students must have strong knowledge about coping strategies.

CONCLUSIONS

Medical students have to get through the university and to endure lots of pressure and stress until they become doctors. Our study proves that depression, the strength of motivation and stressors are affecting the somatic and psychological health and that they also have an impact on academic activity and satisfaction. The results are important for students and for the academic staff. In order to help them prevent or diminish the level of stress experienced during their academic years we need to have lectures in the curricula information about medical psychology and coping strategies.

EPIDEMIOLOGIC RESEARCH REGARDING THE IMPACT OF RISK FACTORS ON HEALTH-RELEATED QUALITY LIFE IN CANCER PATIENTS (Abstract): **Aim:** To assess the health-related quality of life in cancer patients and the relative and attributable risks for the degree of dissatisfaction related to intrinsic and extrinsic factors. **Material and methods**: Our research included 128 cancer patients treated at the Surgical Clinic II of the Iasi Regional Cancer Institute between December 2014 and June 2015. Thus, data were collected by using an inquiry sheet derived from the SF-36 questionnaire, which included closed and open questions about the quality of life, socio-demographic data and such risk factors as smoking, alcohol use, related diseases and risk behaviours. **Results:** The patient sample had a mean age of 60.85 years, 51.6% of them lived in urban areas, were high school graduates, and of low economic status. **Discussion:** As to the behavioural risk factors we found that over 80% of the patients were non-smokers, did not use alcohol, and were normal weighted. Pain was experienced by 70.7% of the cancer patients and depression affected 74% of the study cases. Patients were asked to self-assess their own health status on a scale of 0 (worst) to 100 (the best health status). **Conclusions:** Our study showed a poor health status (mean score 65) in the study cancer patients. The relative and attributable risks for the degree of dissatisfaction related to intrinsic and extrinsic factors were calculated and ranked factors in decreasing order: smoking, depression, pain, alcohol use, male gender, obesity, low income. We found that prolonged suffering affects the psyche and causes depression and that the patients of low financial status, most of them living in villages, have difficulty in accessing medical care. The obtained data about the quality of life in relation with risk factors are in agreement with the data in the literature. **Keywords:** QUALITY OF LIFE, DISSATISFACTION, QUESTIONNAIRE, ONCOLOGY.

The World Health Organization (WHO) defines quality of life as an individuals' perception of their position in life, in relation to their goals and value system, accepted from the perspective of the decisions they make. Quality of life in medicine is the physical, mental and social well-being, and also the ability of patients to perform their daily activities (1, 2).

By assessing symptom progression pa-

tient's quality of life cannot be adequately quantified because, besides measuring the results in terms of symptoms and functioning, patient's view on treatment and its way of administration is also very important (3, 4).

Besides the evaluation of quality of life by objective clinical criteria, an epidemiological approach became necessary as it analyses the efficiency of medical interventions in chronic and incurable diseases in which only a temporary relief can be obtained and treatment is aimed at prolonging patient's life and making it more comfortable. Epidemiological studies are focused on the impact of disease and its treatment on patient's physical and emotional state and lifestyle (5, 6). Health-related quality of life (HRQL) is a complex concept that includes positive and negative aspects of physical, mental and social health, subjective health status (patient's perspective of his health), the impact of this perception on his life and the influence of health and medical care on quality of life (7, 8, 9).

MATERIAL AND METHODS

Our researche included 128 cancer patients treated at the Surgical Clinic II of the Regional Oncology Institute Iaşi between December 2014 and June 2015. Data were obtained in cooperation with the medical personnel and patients. After obtaining the informed consent, all study subjects completed the questionnaire.

We used a self-administered questionnaire derived from SF-36 quality of life questionnaire, which included closed (precoded) questions (the respondent could choose an answer from a preset list of answer choices, quantified by using a scale) and open (postcoded) questions. The questionnaire had a general information module, including identifying and sociodemographic data and questions about way of life outside hospital and risk behaviour (smoking, alcohol use and related diseases). Control questions were used to check the constancy of the expressed opinion (9).

The impact of risk factors on patient satisfaction was evaluated and interpreted by calculating the relative risk, attributable risk, p value and chi – square.

RESULTS

Our epidemiological questionnaire was completed by 128 cancer patients treated at the Surgical Clinic II of the Regional Oncology Institute Iaşi (mean age 60.85, range 18-85 years). Of the 126 patients who answered the question about gender, 51.6% were male and 48.4% female; 51.2% of the patients lived in urban and 48.8% in rural areas.

A low percentage of our study patients were employed (25%), which correlates with a high level of cancer-related disability and a higher frequency of this disease in the elderly.

Most of the patients had a high school diploma (48.4%), 25.4% a secondary school diploma, 14.8% higher education, and 11.5% had only a primary school diploma. Most patients had a stable social status - 72.5% were married and over 70% had a low financial status (monthly personal or household income per person under 1000 lei).

Evaluating the behaviour risk factors, we had found that the vast majority of patients were non-smokers (106 - 82.8%), did not use alcohol (107 of the 125 patients who answered, 85.6%), ate a healthy diet (84 of 127 - 66%) and were normal weighted (83 – 64.8%).

Most of the patients (70.7 %) had experienced pain occasionally, 13% had constant

pain and only 16.3% had no pain (tab. I).

Because cancer is an invalidating chronic disease, depression had affected most of our patients (74% - 88 of the 119 patients who answered); only 26% of the cases were in a good mood (tab. II).

TABLE I

Pain frequency in our lot of patients

Pain	Frequency	Percent	Cum Percent		95% Conf Limits		
No pain	20	16.3%	16.3%		1	10.2%	24.0%
Sometimes	87	70.7%	87.0%		2	61.9%	78.6%
Permanently	16	13.0%	100.0%		3	7.6%	20.3%
Total	123	100.0%	100.0%				

TABLE II

Depression frequency in our patient sample

Depression	Frequency	Percent	Cum Percent		95% Conf Limits		
No depression	31	26%	26.1%		1	18.4%	34.9%
Sometimes	74	62.2%	88.2%		2	52.8%	70.9%
Very often	14	11.8%	100.0%		3	6.6%	19.0%
Total	119	100.0%	100.0%				

We asked the patients to self-assess their own health status on a scale from 0 (the worst imaginable health) to 100 (the best health state). A score of 80-100 indicates a good health status and the mean score obtained in our study patients (65 points) indicated a poor health state (tab. III).

TABLE III

Mean score of life satisfaction in our patient sample

Obs	Total	Mean	Variance	Std Dev
119	7747.0000	65.1008	415.6677	20.3879

Minimum	25%	Median	75%	Maximum	Mode
0.0000	50.0000	70.0000	80.0000	100.0000	50.0000

DISCUSSION

Epidemiological analysis of the impact of risk factors on the level of life satisfaction

Smoking was proved to be a risk factor associated with lower levels of satisfaction with relative risk (RR) 4.82 (2.69<RR< 8.6). Chi-square was 27.11. P value was 0.0001, a statistically significant result. The attributable risk (AR) was 50.42, meaning that the chance for smokers to have poor self-perceived health status is higher with 50.4 than for non-smokers.

Excessive alcohol use proved to con-

tribute to a decrease in the level of satisfaction with RR 1.19 (0.9<RR< 1.52). Chi-square was 1.36, P value = 0.24. This is not a statistically significant result. The attributable risk was 12.72, meaning that the chance for alcohol users to have a poor self-perceived health status is higher with 12.72 than for non-alcohol users.

Unhealthy diet contributes to a decrease in the level of satisfaction RR 1.16 (0.93<RR< 1.44), chi-square = 1.56, P value 0.21; this is not a statistically significant result. The attributable risk was 10.60, meaning that the chance for the people who eat unhealthy food to have a poor self-perceived health status is higher with 10.60 than for people who eat healthy food.

Obesity can affect the level of satisfaction with RR 1.15 (0.92<RR< 1.43); chi-square was 1.4; P value = 0.23, statistically insignificant result. The attributable risk was 9.92, meaning that the chance for the obese patients to have a poor self-perceived health status is higher with 9.92 than for normal weighted patients.

The male gender proved to be a risk factor for a decreased level of satisfaction with RR 1.19 (0.94<RR< 1.54), chi-square 2.27, and P value 0.13. This is a statistically insignificant result. The attributable risk was 12.18, meaning that the chance for men to have a poor self-perceived health status is higher with 12.18 than for women. Other authors point out that the age-related incidence and mortality are higher in males than in females (1, 9).

Low economic status can contribute to a decrease in the level of satisfaction with RR 1.1 (0.84<RR< 1.45), chi-square 0.49, P value 0.48, statistically insignificant result. The attributable risk of 6.32 means that the chance for people with low income to have a poor self-perceived health status is higher with 6.32 than for people with an income over 1000 lei/month.

TABLE IV

Risk factors which can contribute to health status assessment

Risk factors	Share	Score		
		< 80	> 80	*Total*
Smoking	Smokers	14	8	22
	Non smokers	14	92	106
	Total	28	100	128
Alcohol use	Present	17	4	21
	Absent	73	34	107
	Total	90	38	128
Nutrition	Unhealthy	34	10	44
	Healthy	56	28	84
	Total	90	38	128
Obesity	Present	36	11	47
	Absent	54	27	81
	Total	90	38	128
Gender	Male	51	16	67
	Female	39	22	61
	Total	90	38	128
Financial status (income per month)	< 1000 lei	67	26	93
	> 1000 lei	23	12	35
	Total	90	38	128
Pain	Present	80	28	108
	Absent	10	10	20
	Total	90	38	128
Depression	Present	13	1	14
	Absent	69	45	114
	Total	82	46	128

Pain lowers the level of dissatisfaction with RR 1.48 (0.92<RR< 2.33); chi-square was 4.69, P value = 0.03, statistically significant result. The attributable risk was 24.07, meaning that the chance for people who ex-

perience pain to have a poor self-perceived health status is higher with 24.07 than for people who do not experience pain, as also mentioned by other authors (2, 4, 5, 10).

TABLE V

Relative and attributable risks for the level of dissatisfaction related to intrinsic and extrinsic factors, in descending order

Factors	RR	AR
Smoking	4.48	50.42
Depression	1.53	32.33
Pain	1.48	24.07
Alcohol use	1.19	12.72
Male	1.19	12.18
Unhealthy diet	1.16	10.6
Obesity	1.15	9.92
Low income	1.1	6.32

Depression is an important risk factor for a lower level of satisfaction with RR 1.53 (1.25<RR< 1.89); chi-square was 5.66, P value = 0.001, statistically significant result. The attributable risk was 32.33, meaning that the chance for the patients who experience depression to have a poor self-perceived health status is higher with 32.33 than for patients without depression.

In tables IV and V we had analysed the importance of risk factors affecting the quality of life in cancer patients.

CONCLUSIONS

Our study showed a poor health status (mean score 65) for the cancer patients. We calculated the relative and attributable risks for the degree of dissatisfaction related to intrinsic and extrinsic factors and ranked these factors in decreasing order: smoking, depression, pain, alcohol use, male gender, obesity, low income. We found that prolonged suffering affects the psyche and results in depression, and that the patients of low financial status, most of them living in rural areas have difficulty in accessing medical care. The obtained data about the quality of life in relation with risk factors are in agreement with the data in the literature.

A NEW SPECTROPHOTOMETRIC METHOD FOR THE ASSAY OF LISINOPRIL (Abstract) **Aim:** A new spectrophotometric method for the assay of lisinopril using 2,4-dinitrophenol as reagent is described. **Material and methods:** The method involved the addition of 2,4-dinitrophenol to lisinopril in methanol followed by absorbance measurement at 400 nm. Experimental conditions that provide wide linear range, maximum sensitivity, selectivity, accuracy and precisions were optimized. **Results and discussions:** Beer's law was obeyed in the concentration range 2.0-14.0 µg/mL. Linear regression equation of calibration graph was A = 0.005 + 0.045 · concentration, with a regression coefficient (*r*) of 0.9995 (*n* = 8). The limits of detection (LOD) and quantification (LOQ) calculated according to the ICH guidelines were 0.42 and 1.42 µg/mL, respectively. Accuracy and precision of the assays were determined by computing the intra-day and inter-day variations at three different lisinopril concentrations; the intra-day and inter-day RSD was < 1.43% and accuracy was better than 1.72 %. **Conclusions:** The proposed method is simple, easy to perform, sensitive, linear, precise, accurate and robust. **Keywords:** LISINOPRIL, ASSAY, SPECTROPHOTOMETRY, 2,4-DINITROPHENOL.

Lisinopril (fig. 1) is chemically known as N2-[(1S)-1-carboxy-3-phenylpropyl]-L-lysyl-L-proline. It is a drug of the angiotensin converting enzyme inhibitor class that is primarily used in the treatment of hypertension, congestive heart failure, heart attacks and also in preventing renal and retinal complications of diabetes. Historically, lisinopril was the third angiotensin converting enzyme inhibitor, after captopril and enalapril, and it was introduced into therapy in the early 1990s. Lisinopril has a number of properties that distinguish it from other angiotensin converting enzyme inhibitors: it is hydrophilic, has a long half-life and high tissue penetration and it is not metabolized by the liver enzymes (1).

This paper presents a UV-Vis spectrophotometric method for the assay of lisinopril using 2,4-dinitrophenol. The developed method was validated using the following criteria: linearity, detection and quantification limits, precision, accuracy, and robustness (2-5).

MATERIAL AND METHODS

The reagents used in the development of the method were: lisinopril - 100.03% reference substance (Lupin, India), 2,4-dinitrophenol (Fluka) and methanol

(Merck).

The following solutions were used:

- 1 mg/mL lisinopril stock solution: 100 mg lisinopril were dissolved in methanol in a 100 mL volumetric flask;

- lisinopril working solutions with concentrations between 2 and 100 µg/mL lisinopril were obtained by diluting the stock solution with methanol;

- 0.5% solution of 2,4-dinitrophenol: 500 mg 2,4-dinitrophenol were dissolved in methanol in a 100 mL volumetric flask.

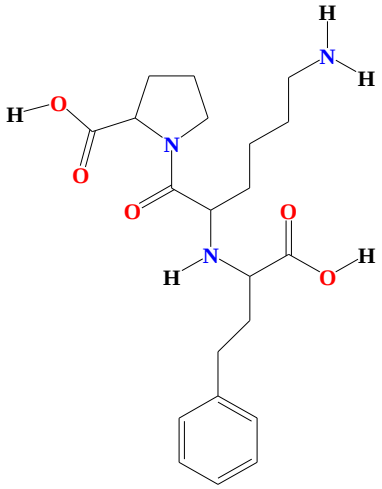

Fig. 1. The chemical structure of lisinopril

A Hewlett Packard 8453 UV-Vis Spectrophotometer, a Kern 770 analytical balance and an Ultrasonic 08849-02 sonicator were used.

Principle of the method: lisinopril forms with 2,4-dinitrophenol in methanol a yellow compound which can be spectrophotometrically measured at 400 nm.

In order to establish the optimum detection wavelength 2 mL of the 50 µg/mL lisinopril working solution were mixed with 1 mL 0.5% 2,4-dinitrophenol solution and 2 mL methanol. The UV-Vis absorption spectrum was recorded with 1 cm cell, after 15 minutes.

In order to establish the optimum concentration for the reagent solution, five solutions of 2,4-dinitrophenol (0.1%, 0.25%, 0.5%, 0.75% and 1%) were used, while the parameters of the method were unchanged.

Procedure: 1 mL of lisinopril working solutions with concentrations in the range 10-70 µg/mL were mixed with 1 mL 0.5% 2,4-dinitrophenol solution and 3 mL methanol. The absorbance was measured after 15 minutes at 400 nm versus a blank solution prepared in similar conditions.

RESULTS AND DISCUSSIONS

From the analysis of absorption spectra (fig. 2), we observed a maximum absorbance for the reaction product at 400 nm. That wavelength was used for all measurements.

The best concentration of 2,4-dinitrophenol reagent solution was established to be 0.5%, because when using that particular solution the maximum absorbance measured at 400 nm had the greatest value (tab. I). After studying the stability of the samples it was established that the chemical reaction between lisinopril and 2,4-dinitrophenol was final 15 minutes after the reagent was added (tab. II). Also, it was proved that the absorbance remained almost the same for at least another 20 minutes, time sufficient enough for the analysis to be performed.

Linearity was studied in the 0.4 - 20 µg/mL concentration range (fig. 3). The obtained data were statistically evaluated (tab. III) and the calibration curve was obtained (fig. 4).

According to the experimental data, the developed method was linear in 2 – 14 µg/mL concentration range. When this

concentration range was compared with that of other published methods we found that it was very similar, but this new method had the following advantage: it did not require the use of rare or complex reagents. It is simple and easy to perform (6-10).

10.0	0.46574	0.45892	0.47014	0.46025	0.46376
12.0	0.56559	0.57421	0.56142	0.56842	0.56741
14.0	0.63934	0.63412	0.64721	0.64455	0.64131
16.0	0.65435	0.64125	0.66120	0.64125	0.64951
18.0	0.64560	0.65744	0.64855	0.65470	0.65157
20.0	0.63547	0.65122	0.64177	0.67444	0.65073
Correlation and regression coefficients r = 0.9995, r^2 = 0.9991; Standard error = 0.0065; Intercept = 0.005; Slope = 0.046					

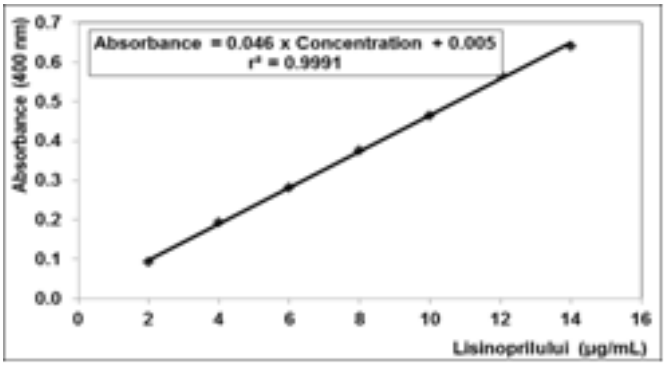

Fig. 4. Calibration curve

The calibration curve equation was established:

- Absorbance = 0.046 x Concentration – 0.005.

- Detection and quantification limits were calculated using the following formulas (2, 3):

- LD=3 x Standard error / Slope = 0.42 µg/mL

- LQ=10 x Standard error / Slope = 1.41 µg/mL.

Precision: three solutions of 6, 8 and 10 µg/mL lisinopril were used. Three assays were performed for each concentration. Two sets of assays were performed in different days in order to evaluate the intermediary precision.

The sample concentrations were calculated using the calibration curve equation (tab. VI). We observed that the relative standard deviation for each data set and for both data sets together was less than 2% (at most RSD = 1.43%) (4), proving that the proposed method was precise.

In order to establish the accuracy of the method, lisinopril solutions of 6, 8 and 10 µg/mL were analyzed. For each concentration, three determinations were performed (5).

The concentration of the samples was calculated from the experimental values of absorbance, using the regression curve equation (tab. IV). For the studied concentration range recovery was 100.59%, the mean was between 98.51% - 102.39%, and the relative standard deviation was lower than 2% (RSD = 1.42 %). Those values proved that the proposed method was accurate.

The evaluation of robustness was performed for system suitability to ensure the validity of analytical procedure. That was done by varying the instrument, analyst, and time of study. The analysis was performed also on a 1700 Shimadzu UV-Visible spectrophotometer. Interday and intraday analyses were performed by various analysts. Reproducibility of the results confirmed the robustness of the method.

TABLE IV

Study of the precision and the accuracy of the method

Concentration (µg/mL)	Precision		Intermediate precision		Accuracy	
	Real concentration (µg/mL)	RSD %	Real concentration (µg/mL)	RSD %	Absorbance	Recovery (%)
6	5.9650	1.768	5.965	1.708	0.28411	100.86
	5.8428		6.0606		0.27455	97.40

	10.1894		9.9141		0.47855	102.80
	9.9034		10.2463		0.46625	100.12
					Mean	100.39

CONCLUSIONS

A UV-VIS spectrophotometric method was developed for the assay of lisinopril using 2,4-dinitrophenol. The reaction product showed a maximum absorbance at 400 nm.

The analytical method was validated by establishing the linearity domain in the range of 2.0 – 14 μg/mL, with a correlation coefficient of r = 0.9995, the detection limit was 0.42 μg/mL, the quantification limit was 1.41 μg/mL lower than the lowest concentration from the linearity domain, method precision RSD% = 1.61% and the accuracy evaluated through recovery was R = 100.39%.

In conclusion, the proposed method is simple, easy to perform, sensitive, linear, precise, accurate and robust.

ASSESSMENT OF PERSONAL QUALITIES OF HEALTHCARE PROFESSIONALS– DETERMINING FACTOR FOR THE IMPROVEMENT OF HEALTHCARE SERVICES IN THE ROMANIAN HEALTH (Abstract). **Aim:** A quality health care system has been a perpetual desideratum. The increased importance of assessing quality of health care is lately emphasized by the alternation between the level, role and place of technology in healthcare and especially by the need for a balance between the values of Hippocratic medicine and the valences of technologized medicine of today society. **Material and methods**: The study is based on the evaluation of responses to an online questionnaire from 1013 health professionals in different regions of Romania, questionnaire hosted by SurveyMonkey. **Results**: Sacrifice, humanity, dedication, knowledge, respect and rigor were the top key traits according to our responders. The qualities of health professionals and how they are assessed are undoubtedly an important source for determining the qualities to be formed during education, and which are the basis for a healthcare system based on quality and competence and increasing patient satisfaction. **Keywords**: HEALTHCARE SYSTEM, PROFESSIONAL QUALITIES, SATISFACTION OF HEALTHCARE PROFESSIONALS.

The safety and quality of healthcare services are worldwide concerns. Many problems arise from human and health system errors, but also from the dissatisfaction and lack of motivation of healthcare personnel. If initially the concept of patient satisfaction seemed to be an element of analysis relevant only for medical practice, increasingly more voices believe that both human components of the health system: healthcare professionals and patient, have be taken into account realizing that negative events, including the low level of medical staff satisfaction is an important factor that can influence the quality of care. If deaths from specific disease are not difficult to quantify, those produced as a result of poor care are more difficult to identify, although according to some studies they are the 8th leading cause of death in the USA

(5), mostly of them avoidable (3).

The qualities of healthcare professionals are the least studied factors in the equation quality of care - patient satisfaction, and should not be seen as individual factors but as interconnected causes that may intervene both subjectively and individually, but leading to a phenomenon at the level of the whole system. Factors such as negative stress can influence both the health status of health professionals and how they act during professional activity. If scales and standards to measure occupational stress are available, few studies were dealing with moral stress, although the crisis of moral models is quite widespread throughout society (9).

Each society and field area is under the sign of one of the most difficult to distinguish human quality: the ethical-moral qualities of the person who provides health care, especially when the ethical dilemmas the healthcare professionals are faced with may generate tensions and thus diminish their ability to focus solely on the quality of care. In this context it is important to understand that: "If true collaboration is to be achieved, it is important to understand the perspectives of others" (6).

Ensuring quality healthcare services in Romania has been a significant concern since 1989 and especially in the perspective of our country's integration in the European Union (EU) and the need to harmonize the national healthcare system with EU rules. Quality of healthcare services is influenced by several factors, of which the more frequent are the wide variations in medical practice performance, unequal access to healthcare or longer waiting time to access certain services (1). In recent years, in Romania, the main criterion analyzed by opinion polls to measure the quality of healthcare was patient satisfaction, often using own tools or instruments internationally validated and adapted to the conditions in our country (2).

Internationally, there are validated studies that evaluated performance in healthcare; however, we should not forget that healthcare employee satisfaction is of utmost importance when it comes to quality of care, in Romania, as in other countries in the world, they being faced with many problems related to personnel cut, less funding allocated to health care and the increased demand for health services (2, 4). Moreover, it has already been proven that the performance of the health system and the level of care are directly influenced healthcare employee satisfaction (7).

The basis for providing healthcare services in health management and medical practice is represented by the *nine* dimensions for quality assessment: professional competence, accessibility, effectiveness - the applied procedures and treatment; efficiency; interpersonal relations, continuity, security, physical infrastructure and comfort, choice of supplier, type of insurance or treatment (8, 10).

The aim of this study was to assess healthcare employee satisfaction by the study of 19 characteristics of significance in performing healthcare activities, related to competence, self-sacrifice, self-control, responsibility etc.

MATERIAL AND METHODS

A poll/survey was conducted with the help of an online questionnaire using the SurveyMonkey platform. The study included a total of 1013 health professionals working in Bucharest, Iasi, Cluj Napoca, Tg. Mures, Timisoara and Craiova university hospitals. The questionnaire included questions related to the 19 characteristics that define the medical profession. The analyzed

characteristics were divided into three distinct categories: 1) included competence, dedication, sacrifice, literacy and humanity; 2) included dedication, knowledge, skills, perfection, responsibility, "cold blood", self-control and tenacity; and 3) creativity, experience, intelligence, accuracy, respect, rigor and speed. A correlation analysis was performed to identify the main issues that may be associated with healthcare employee satisfaction. The results were considered statistically significant at a confidence interval of 95%.

RESULTS

Following the statistical analysis of study group composition we found that according to age variable the group of responders had a homogeneous distribution. Distribution of the study group according to the variable "Age" showed that most subjects (28.3%) were in the age range 45-50 years, followed by those in the age range 35-45 years (21.5%) and 30-35 years (20.4%). Very close percentages were recorded for the subjects below 30 years (14.7%) and those over 50 years (15%) (tab. I).

The variable "level of education" showed a quasi-uniform distribution, the study group being composed of people with higher education, of which one with postgraduate studies (tab. II).

TABLE I

Distribution of participants by "Age"

Age (years)	Frequency	Percentage	Cumulative percentage
Under 30	149	14.7	14.7
30-35	207	20.4	35.1
35-45	218	21.5	56.7
45-50	287	28.3	85.0
Over 50	152	15.0	100.0
Total	*1013*	*100.0*	

TABLE II

Distribution of participants by "Level of education"

Level of education		Frequency	Percentage	Cumulative percentage
Valid	Higher education	1012	99.9	99.9
	Postgraduate	1	0.1	100.0
	Total	*1013*	*100.0*	

The variable "Length of service in the health system" showed that most participants have worked in this field for over 20 years old (37.8%), followed by those with a length of service of 10 to20 years (25.3%) and 5 to 10 years (22.2%), the fewest being those with a length of service less than 5 years (14.7%) (tab. III). As 63% of the respondents had over 10 year experience in healthcare it gave us the opportunity to get information from people who are familiar with the health system and managed to gather enough experience, including in communication with the patient and under-

standing their objective needs.

Ranking of competence, commitment, sacrifice, literacy, humanity, characteristics that define the medical profession showed that the surveyed people made a clear distinction between competence and the other features. When asked to name three characteristics that define the medical profession, an equal number of doctors, 338 (33.4%) responded that sacrifice and humanity, respectively were the defining characteristics of their profession and a total of 335 physicians (33.1%) indicated competence (tab. IV).

TABLE III

Distribution of participants by "Length of service in the health system"

Length of service in healthcare system (years)	Frequency	Percentage	Valid percentage	Cumulative percentage
Under 5	149	14.7	14.7	14.7
5-10	225	22.2	22.2	36.9
10-20	256	25.3	25.3	62.2
Over 20	383	37.8	37.8	100.0
Total	*1013*	*100.0*	*100.0*	

TABLE IV

Distribution of participants by characteristics that define medical profession (competence, devotion, sacrifice, literacy, humanity)

Traits	Frequency	Percentage	Valid percentage	Cumulative percentage
Competence	335	33.1	33.1	33.1
Devotion	1	0.1	0.1	33.2
Sacrifice	338	33.4	33.4	66.5
Literacy	1	0.1	0.1	66.6
Humanity	338	33.4	33.4	100.0
Total	*1013*	*100.0*	*100.0*	

A second category of individual characteristics that define the medical profession included the following items: dedication, knowledge, gifted, perfection, responsibility, cold-blooded/self-control, determination. Very close percentages (16.5 to 16.8%) were obtained for most characteristics, except for determination which was considered important by a single physician who participated in the survey (0.1%) (tab. V).

The third category of individual characteristics that define the medical profession was composed of the following items: creativity, experience, intelligence, accuracy, respect, rigor, general knowledge, and speed. Six of the 8 items had approximately equal percentages, 16.3% to 16.8%, the remaining two, creativity and general knowledge, with a percentage of only 1% each, surprisingly ranked last; this can be explained by the fact that medical profes-

sion being considered a very rigorous profession which requires a thorough analysis, creativity and general knowledge, the more so as medicine is associated with the need for continuous learning are not seen as valuable attributes (tab. VI).

TABLE V

Ranking of characteristics that define medical professions (dedication, knowledge, gifted, perfection, responsibility, composure, determination)

Traits	Frequency	Percentage	Valid percentage	Cumulative percentage
Dedication	170	16.8	16.8	16.8
Knowledge	170	16.8	16.8	33.6
Gifted	169	16.7	16.7	50.2
Perfection	169	16.7	16.7	66.9
Responsibility	167	16.5	16.5	83.4
Cold blood	167	16.5	16.5	99.9
Determination	1	0.1	0.1	100.0
Total	*1013*	*100.0*	*100.0*	

TABLE VI

Ranking of the characteristics that define medical profession (creativity, experience, intelligence, accuracy, respect, rigor, general knowledge and speed)

Traits	Frequency	Percentage	Valid percentage	Cumulative percentage
Creativity	1	0.1	0.1	0.1
Experience	169	16.7	16.7	16.8
Intelligence	169	16.7	16.7	33.5
Accuracy	165	16.3	16.3	49.8
Respect	170	16.8	16.8	66.5
Rigor	170	16.8	16.8	83.3
General knowledge	1	0.1	0.1	83.4
Speed	168	16.6	16.6	100.0
Total	*1013*	*100.0*	*100.0*	

The analysis of all responses revealed that according to our subjects the medical profession is defined by three fundamental characteristics: humanity, sacrifice and competence.

DISCUSSION

All subjects had higher education, and only one postgraduate studies. Most of the subjects were older than 45 years, and only few under the age of 30 years. The obtained results allowed us to hierarchize the characteristics considered by healthcare professionals important in the practice of medicine.

Considering the top two in each category, the most important attributes were: sacrifice, humanity, dedication, knowledge, respect and rigor. The same characteristics

were selected by healthcare professionals regardless of length of service in the health system (5, 6).

CONCLUSIONS

In our study, human resources management in medical institutions should also be based on the assessment of qualities required to healthcare professionals, and ideally staff recruitment and selection should not be based solely on knowledge but also on the most important qualities that those who wish to practice medicine should have. To meet the challenges of the health system is absolutely necessary that these characteristics to be formed during medical education and "maintained" by forms of continuing education.

QUALITY OF LIFE WITH MASTECTOMY FOR BREAST CANCER, IN TERMS OF PATIENTS' RESPONSES OF SF-36 QUESTIONNAIRE (Abstract): **The aim** of the study was to describe the quality of life in female patients with mastectomy performed for breast cancer. **Material and methods**: The study was carried out in Iaşi, between October 2014 - January 2015, on a sample of 23 patients with mastectomy, using the SF-36 Questionnaire (Short Form-36) in a single visit, with direct questioning of patients; a secondary instrument was a general anamnestic questionnaire referring on age group, area of residence, type of surgery, associated diseases, family history, psycho-emotional traumas. **Results**: The overall profile of the studied case was: woman of 40-49 years (47.8%), from urban area (82.6%), with a family history of neoplastic pathology (43.5%), with psycho-emotional traumas (73.9%) and a self-estimated general health as "moderate" (26.1%), with "a lot of energy" only "some of the time" (43.5%), "feeling worn out" (43.5%), and "cutting down the amount of time spent on work or other activities" (69.6%), with "moderate" (34.8%) or even "intense" (21.7%) "bodily pain", "some of the time" feeling "very nervous" (43.5%) and "so down in the dumps that nothing could cheer her up" (39.1%). The strongest correlation was found between the variable "cut down the amount of time spent on work and other activities" as a result of "physical health" (Role-physical items) and "limited in kind of work or other activities" (r=0.8981). **Conclusions**: Application of SF-36 Questionnaire in female patients with mastectomy for breast cancer highlighted that strenuous and moderate activities were limited than about half of the surveyed cases, somatic pain affecting their work and normal activities and physical and emotional health influenced the social activity of patients for more than half of the lot. It is necessary to extend the study in order to bring relevant data on the quality of life of these patients, in the social, economic and cultural center of Romania. **Keywords**: QUALITY OF LIFE, SF-36 QUESTIONNAIRE, MASTECTOMY, BREAST CANCER.

According to the World Happiness Report for 2012, Romania was ranked 90 in the world, with a score of 5.033, between Kyrgyzstan and Zambia (first was Denmark). Comparing the term of *happiness*, therefore, the *quality of life*, Romania has lost 0.186 points during 2005-2007 (1). The first survey on quality of life in the population of European countries was performed in 2006 (2). At that moment, Romania, as a candidate country for EU, was below the continent average, with a score of 6.2. According to the third survey conducted in 2012, Romania has very low scores on several indica-

tors of quality of life, compared to other countries, and, on the perception of quality of life in terms of health services, ranked the next to last position (3).

The notions of *subjective well-being* and *happiness* have a long tradition as core elements of the concept of *quality of life*. However, until recently, these ideas were not too often considered beyond the purpose of statistics. In recent years, this view has changed, especially after the publication of the report of the Commission on the Measurement of Economic Performance and Social Progress, which recommended that national statistical agencies collect and make public aspects of these concepts. According to the researchers from the United Nations (4), the quality of life is an intersection of notions of professional status, health level, balance between work and life, education and skills, social connections, civic engagement of the individual, environment quality and personal safety.

There are numerous questionnaires to assess the quality of life, validated on various healthy population groups and also on groups with different pathologies. *SF-36* (Short-Form 36-Item Health Survey) uses eight scales with questions regarding physical functioning (first 10 items), diseases caused by physical problems or role-physical (the next 4 items), bodily pain (2 items), general health (5 items), vitality (4 items), social functioning (2 items), emotional problems caused by social dysfunctions or role-emotional (3 items), and mental health (5 items) (4).

In 2012, in Romania was recorded breast cancer incidence of 50.04 cases per 100,000 inhabitants, an average value (which ranks 33 among European countries) compared to the top three worldwide, those in Belgium (111.98%ooo), Denmark (105.0%ooo), and France (104.46%ooo) (5). Approximately 12.3% of women will be diagnosed with breast cancer at some point in their lives, in the coming years, as stated in a prognosis made by the National Cancer Institute, USA, based on data collected between 2009 and 2011 (6). In recent decades, the five-year survival of female patients with breast cancer increased from 75.2% in 1975 to 86.5% in 1994 and 90.6% in 2006 (6). Therefore, it is necessary to take into account the quality of life of those women who received successful anti-cancer therapies, having, as the main target, the increase of survival.

The aim of our study was to describe the physical and emotional impact on quality of life lived by women with mastectomy performed for clinical and paraclinical diagnosis of breast cancer, using the SF-36 questionnaire.

MATERIAL AND METHODS

The study was conducted between October 2014 - January 2015 on a sample of 23 female patients treated surgically at Regional Institute of Oncology Iaşi (19 patients) and "St. Spiridon" Emergency Hospital Iaşi (4 patients). Inclusion criteria for the study were: clinical and paraclinical diagnosis of breast cancer; total or partial mastectomy. Exclusion criteria: patients who refused the participation in the study.

Informed consent of research participants received the Ethical Approval from the Research Ethics Committee of the University of Medicine and Pharmacy, of Regional Institute of Oncology, and "St. Spiridon" Hospital. Every patient participating in the study became aware of its contents and signed two copies of it, one of which remained in the project file and the other to the participant.

The study was conducted in a single visit with direct questioning of patients as the method. The main tool used was SF-36 questionnaire validated for healthy population of Romania in a project conducted by the "Romanian Association for Public Health and Health Management" and "Centre for Urban and Regional Sociology", Bucharest (7).

The second instrument used was a general anamnesis questionnaire with items regarding age group, area of residence, type of surgery, associated diseases, family history, and psycho-emotional traumas 3-5 years before breast cancer diagnosis.

Statistical processing was performed using MS Excel 2010 and EPI/INFO 7 software.

RESULTS

Statistical descriptive data for the study group. Distribution by age group showed a preponderance of cases at 40-49 years (47.8%), followed by group 50-59 (21.7%), 30-39 and 60-69 (13.05%), then 70-79 (4.4% of cases), with a mean of 50.59 (standard deviation = 11.07). Age histogram tended to be within normal limits, describing Gaussian distribution. Patients were mostly from urban areas (82.6%), mentioning cities in the North-East region of Romania. All patients were hospitalized for clinical and paraclinical diagnosis of breast cancer; the surgical treatment was total mastectomy in 86.9% of the patients and partial mastectomy / lumpectomy (sector, quadrant) in 13.1%; axillary lymph node dissection was performed in 100% of cases.

Patients mentioned tumors and depression as associated diseases in 3 cases (13.05%) respectively, but 2 patients indicated the presence of autoimmune diseases in personal history. Other conditions were cardiovascular diseases (ischemic heart disease, arterial hypertension) and diabetes mellitus. Family history of neoplastic pathologies was positive in 10 cases (43.5%); 7 patients (30.4% of the total group) mentioned malignant and benign tumors of the breast, ovary, prostate and colorectal cancer in first and second degree relatives. Regarding the psycho-emotional traumas of the past 3-5 years, 17 patients (73.9%) noticed their presence (divorce - in 2 cases, 8.7%; deaths in family - in 6 cases, 26.1%; other emotional traumas considered important by patients - 11 cases, 47.8%).

Results of SF-36 questionnaire. The questionnaire is divided into two concepts: physical health and mental health. We described statistically each scale of the SF-36 questionnaire and the following results were obtained:

I. *General health scale* included 5 items estimating the own health; patients considered that it was "good" in 52.2% of cases and 26.1% assessed it as "tolerable". One patient (4.3%) mentioned an "excellent" condition and another one, a "bad" state of health. 30.4% of total indicated that it was "definitely true" and "mostly true" they "get sick easier than other people", and 43.5% were denied "absolutely" and "mostly" this fact. 39.1% indicated that it is "definitely" and "mostly true" that were healthy like anybody know, and 34.7% denied this fact. 21.7% of patients expected ("definitely" + "mostly") that "their condition to get worse", 52.2% denied this fact, and 26.1% did not know how to respond. If "definitely and mostly true" that "health is excellent" said 52.2% of patients and that is false, 21.7%.

II. *Vitality scale*: "full of life" felt "much of the time" 30.4% of patients and

43.5% “had a lot of energy” only “some of the time”. No patient chose the answer “none of the time” at this item. Most patients felt “some of the time” “worn out” (34.7%) and “tired” (47.8%), but “all of the time” and “most of the time” only 8.7% and 17.4%, respectively.

III. *Physical functioning scale*. “Vigorous” activities “limited a lot” 43.5% of patients, but “not limited at all” one of them (4.3%); those “moderate” “limited a lot” 26.1% of total cases and “not limited at all” 8 patients (34.8%). "Lifting or carrying groceries” “limited a lot” 47.8% of all cases and “not limited at all” 21.7% of them. About “climbing several flights of stairs”, 39.1% of patients said they were “not limited at all”, but 30.4% indicated that they were “limited a lot” or "limited a little”, respectively; “climbing one flight of stairs” was “not limited at all” for 60.9% of patients. “Walking more than a mile” “limited a lot” and “a little” 56.5% of all cases, but “not at all” 43.5%; “walking several hundred yards” “limited a lot” only 26.1% of patients, and “walking one hundred yards” “limited not at all” in 86.9%. Activities such as “bathing or dressing oneself” “limited a lot and a little” only 43.5% of cases. It is noted that physical functional limitation increased with the increasing of degree of activities difficulty.

IV. *Role-physical scale*. It was found that 69.6% of women “counted down the amount of time spent on work or other activities”, 65.2% “accomplished less than they would like” and 73.9% of patients were limited “in kind of work and other activities” and “had difficulties performing work or other activities”, respectively.

V. *Bodily pain scale* contains items about changes in normal work. Patients experienced bodily pain “moderate” in 34.8% cases and “severe” and “very severe” in 21.7%, which “interfered with normal work” “moderate” in 30.4% of patients and “severe” and “very severe” in 21.7%.

VI. *Social functioning scale* showed how physical health or emotional problems interfered with social activities currently carried out with family and friends. Patients indicated that these activities changed “moderately” in 30.4% of cases and “extremely” in only 8.9%. During the last four weeks, there were times when physical or emotional health influenced social activity of patients, “most of the time” for 17.4% of them and “some of the time” for 34.8%. However, no patient chose the answer “all of the time” at this item.

VII. *Role-emotional scale* highlighted difficulties occurred when performing work or other regular daily activities as a result of any emotional problem such as “feeling depressed or anxious”; those have been reported in more than half of the cases, respectively 52.2% reduced “the amount of time spent on work or other activities” and “accomplished less activities”; 56.5% of patients stated difficulties of achieving them “with the same care as usual”.

VIII. *Mental health scale*. Patients mentioned that “some of the time” felt “very nervous” (43.5%) and “felt so down in the dumps that nothing could cheer them up” (39.1%), but “most of the time” “calm and peaceful” (43.5%). "Downhearted and depressed” were "all of the time” 2 patients (8.7%), others only “some of the time” or “a little of the time” (30.4%). The next item about if she was deemed a “happy person”, 17.4% of the cases mentioned that “some of the time” 4.3% “ a little of the time” or “none of the time”; however, more

than half of sample chose answers such as "all of the time" (26.1%), "most of the time" (17.4%), and "a good bit of the time" (30.4%).

Correlations analysis. The patients' age was positively correlated with the difficulty of carrying out "moderate activities" (r=0.2184), with the "cut down the amount of time spent on work" and the occurrence of difficulties in "performing the work and other activities" (r=0.3530). Also, the variable "age" was positively correlated with variables "been very nervous" (r=0.4298) and "felt so down in the dumps that nothing could cheer them up" (r=0.3938).

The strongest correlations were found between the variable "cut down the amount of time spent on work or other activities" as a result of physical health and "been limited in kind of work or other activities" (r=0.8981), followed by correlation between "intensity of bodily pain" and "extend pain interfered with normal work" (r=0.8711). The next correlation was between the variable "cut down the amount of time spent on work and other activities as a result of emotional problems" and "accomplished less than they would like due to emotional problems" and also "frequency health problems interfered with social activities"(item no. 10) (r=0.8360 in both cases).

It is necessary to notice that there was no correlation (r=0) between the variable "healthy as anybody they know" and "cut down the amount of time spent on work or other activities as a result of physical health", "cut down the amount of time spent on work or other activities as a result of emotional problems", "accomplished less than they would like to due to emotional problems" and "extend pain interfered with normal work" (item no. 8).

Concerning the question of the existence of psycho-emotional traumas, this variable, from the second questionnaire, was positively correlated with items "been very nervous" (r=0.5985), "intensity of bodily pain" (r=0.5456), and "feel downhearted and depressed" (r=0.3887).

DISCUSSION

There are numerous valid instruments used to measure quality of life in breast cancer patients. EORTIQ-C30 questionnaire (European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core Cancer) and that specific for breast cancer (EORTC QLQ-BR23), FACIT-G (Functional Assessment Chronic Illness Therapy-General Questionnaire) and the variant for cancer breast (FACIT-B) were considered the most useful tools and best developed to measure the quality of life in those patients. The various surgical procedures have led to similar results on quality of life assessments, although patients with mastectomy compared with those who underwent conservative treatment have been reported frequently a body image issues and sexual dysfunction.

Regarding systemic therapies, almost all studies have indicated that patients receiving chemotherapy for breast cancer suffered from certain side effects and symptoms that adversely affected their quality of life, as well as adjuvant hormone therapy, although they were associated usually with an increase in survival rates. In patients with metastases, data on quality of life represented prognostic and predictive factors of survival. Psychological distress, anxiety, and depression were common in studies on groups of breast cancer patients, even after years from the date of diagnosis and treatment. Psychological factors were

used, also, as predictors of subsequent quality of life or overall survival of patients with breast cancer.

Sexual functioning of patients with breast cancer, especially those younger, is being reduced, having a negative impact on their quality of life. Antiemetic supportive treatment, for example, or interventions such as counseling, social support, and exercise can improve the quality of life of these patients. Pain, fatigue, arm disability and postmenopausal symptoms are common in patients with breast cancer. Therefore, it is recommended their recognition and management as important aim until they do not start to disrupt their health-related quality of life (8).

Health-related quality of life is now considered an important aim in oncology trials. Studies conducted over the years have shown that the assessment of the quality of life in patients with cancer could improve the treatment and even was considered a prognostic factor indicating the future directions useful for the implementation of effective therapies (9, 10).

Among studies on quality of life, breast cancer received the most attention, for certain reasons, primarily because of the increasing incidence of the disease (over half a million women worldwide are diagnosed with breast cancer yearly – 1.67 million in 2012, 25% of all cancers - and over half a million die from this disease - 522,000 in 2012) (11); secondly, because techniques for early detection and treatment of breast cancer are currently at high standards, increasing significantly the survival time, compared to previous decades; therefore, to study the quality of life in this context should become a priority (9).

Another reason is that the location of the breast neoplastic process affects women at all levels of their identity, thus, to study the quality of life of these patients who have lost breast or breasts should become vital. In addition, women play important roles as life partner, wives, mothers, in every family. When a woman develops breast cancer, all family members are about to develop various types of pathological conditions. Thus, psycho-emotionally speaking, breast cancer becomes a disease of the whole family.

So, a multitude of other reasons could be added. Therefore, the question formulated by many researchers becomes evident: to what extent the quality of life studies have improved therapeutic outcomes and, ultimately, improve the quality of life of women with breast cancer? (10).

CONCLUSIONS

The results of the SF-36 questionnaire used to assess quality of life in female patients with mastectomy for breast cancer highlighted that strenuous and moderate activities limited almost half of the surveyed cases, bodily pain affecting their work and normal activities. Also, physical or emotional health influenced social activity of patients, most of the time and some of the time for more than half of them. The existence of psycho-emotional traumas in patients' history was positively correlated with current physical health or emotional issues.

Analysis of a larger group of patients, including those assisted in hospitals from other university centers, will bring more relevant data concerning the mastectomy performed for breast cancer and quality of life lived in the social, economic and cultural space of Romania.

RESPONSIBILITY AND EXPECTATIONS IN ANTIRETROVIRAL THERAPY – PATIENTS' VERSUS DOCTORS' PERSPECTIVE (Abstract). **Aim:** This paper aims to uncover what patients really expect form ART, and also what infectious diseases doctors expect from a patient's ART regime, thus exploring an important side of adherence to ART. **Material and Methods:** From July to November 2014 we have conducted a qualitative study regarding both patients' and doctors' expectations form the ART. We interviewed 30 patients and 4 doctors. We used semi-structured interviews that were conducted in the Psychosocial Compartment of the HIV/AIDS Regional Center in Iasi. **Results:** The patients we interviewed came from all 6 counties in the Moldova area. Age varied from 16 years to 59 years; 55% were female and 45% male. 30% came from a rural area. The most common expectations that patients have regarding ART are: "to help me live", "not to make me feel sick", "to be easy to take (not to big, not a lot)", "not to show on the outside what I have on the inside". The infectious diseases doctors that we interviewed work in the HIV/AIDS Regional Center in Iasi. Their expectations regarding an ART regimen for patients were: "to reduce HIV viral load", "to increase CD4 cell count" and "to have minimal impact on the proper functioning of other organs". Patients consider themselves the only factors responsible for their own ART adherence in 56.6% of cases; 20% consider the doctor to be responsible for their adherence, 16.6% feel that their family, friends, and spouse are responsible, and 6.6% (2 patients) couldn't answer. Infectious diseases doctors considered that patients are 100% responsible for adhering to the antiretroviral therapy. **Conclusions:** In order to assure adherence to the ART it is important to explore both the doctor and the patient's perspective and to find ways to find a common ground in building a healthy relationship. **Keywords**: HIV/AIDS, ANTIRETROVIRAL THERAPY, ADHERENCE, PATIENTS' EXPECTATIONS, DOCTORS' EXPECTATIONS, RESPONSIBILITY.

Antiretroviral therapy (ART) is essential in maintaining a low HIV viral load, which allows the immune system to function properly and assures a qualitative life style for HIV positive patients (1). However, low rates of adherence to ART are still registered, in spite of all efforts.

In Romania, around 90% of all HIV infected individuals are part of the "pediatric cohort" – young people born in 1986-1989 and infected in the hospital. They were diagnosed at the age of 3-5 years and have lived with HIV/AIDS for more than 20 years. They have a history of up to 10 ex-

perimental drug regimens, having passed from mono – to bi-therapy to HAART (highly active antiretroviral therapy) (2).

The rest of HIV-positive patients are adults infected through unprotected sexual contact or through the use of unsterilized syringes in the case of injecting drug users. They have a shorter history of living with HIV/AIDS and their numbers are continuously increasing.

A highly researched issue regarding people living with HIV/AIDS (PLWHA) is adherence to antiretroviral therapy.

Studies identified a number of factors associated with adherence to ART (3,4):

- Medical aspects and characteristics of the therapy - number of pills/day, ART side effects;
- Social aspects – stigma and discrimination, lack of knowledge and understanding of HIV, the doctor-patient relationship, peer support and family support;
- Psychological aspects – treatment fatigue, IQ, psychopathology, treatment fatigue, disclosure of the diagnosis, responsibility, expectations from ART.

This paper aims to uncover what patients really expect form ART, and also what infectious diseases doctors expect from a patient's ART regime, thus exploring an important side of adherence to ART.

MATERIAL AND METHODS

We realized a qualitative study for a period of 5 months, from July to November 2014. We interviewed 30 patients and 4 doctors. The patients came from all 6 counties in the Moldova area – Iasi, Vaslui, Bacau, Botosani, Suceava, Neamt. The infectious diseases doctors that we interviewed work in the HIV/AIDS Regional Center in Iasi.

We used semi-structured interviews as a method of gathering data. The interviews were conducted in the Psychosocial Compartment of the HIV/AIDS Regional Center in Iasi.

The demographics revealed 55% were female and 45% male (fig. 1); 30% came from a rural area (fig. 2). Age varied from 16 years to 59 years, in concordance with the requirements of qualitative research.

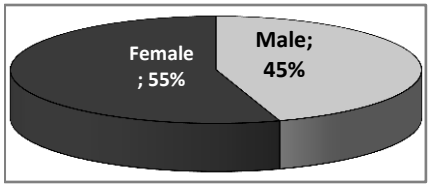

Fig 1. Gender distribution

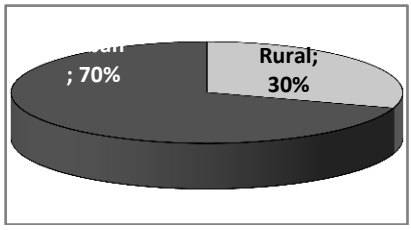

Fig 2. Environment distribution

RESULTS

Patients' expectations revolved around general health and a healthy appearance.

The most common expectations that patients have regarding ART were:

- "to help me live" – Patients fear death, especially due to myths about HIV/AIDS. One of the first questions patients ask after diagnosis is how long they have to live;
- "not to make me feel sick" – Patients fear antiretroviral drug side effects, such as nausea, diarrhea, headaches, skin rash, etc. They expect a therapy that makes them feel better instead of worse;
- "to be easy to take (not to big, not a lot)" – Some patients have difficulty swallowing large pills. Having to take too many

pills a day is an often evoked reason for non-adherence;

- "not to show on the outside what I have on the inside" – The stigma associated with the HIV infection is something that patients often fear. They expect that ART would make have minimal impact on their exterior appearance. This offers a sense of security, because society cannot tell they suffer from this disease.

Patients' expectations from ART show the importance they give to the impact that the therapy has on their overall quality of life, especially on their body's reaction to medication.

The infectious diseases doctors that we interviewed work in the HIV/AIDS Regional Center in Iasi. Their expectations regarding an ART regimen for patients were: "to reduce HIV viral load", "to increase CD4 cell count" and "to have minimal impact on the proper functioning of other organs". Doctors expect pragmatic results from the ART, focusing on the medical aspects.

Patients consider themselves the only factors responsible for their own ART adherence in 56.6% of cases; 20% consider the doctor to be responsible for their adherence, 16.6% feel that their family, friends, and spouse are responsible, and 6.6% (2 patients) couldn't answer (fig. 3).

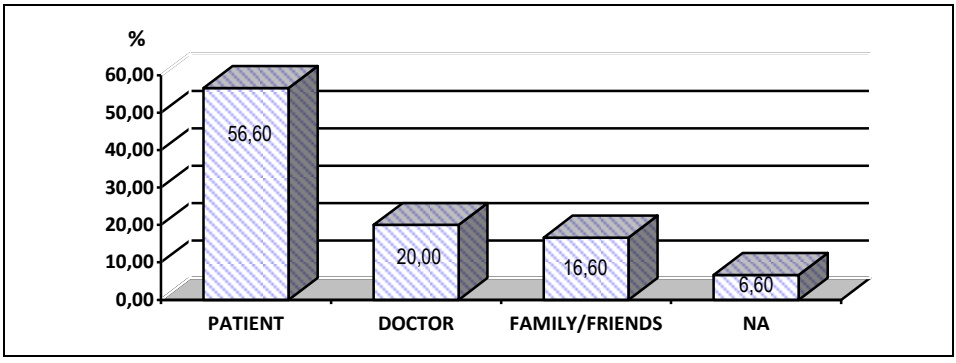

Fig. 3. Patients' perception of responsibility for adherence to antiretroviral therapy

Infectious diseases doctors considered that patients are 100% responsible for adhering to the antiretroviral therapy.

DISCUSSION

Exploring patients' expectations from ART reveals the importance they give to the impact that the therapy has on their overall quality of life, especially on their body's reaction to medication (5). Multiple side effects, such as nausea, diarrhea, headaches, skin rash, etc or a large number of pills to take are, for patients, signs that the therapy did not meet their expectations and therefore a reason to stop taking it (6). This is an important aspect in working towards adherence to antiretroviral therapy.

Doctors expect pragmatic results from the ART. Their perspective is centered on medical aspects.

Even though both doctor and patient aim for a higher quality of life, the meaning of this concept is often different. This is why often the doctor-patient relationship has to suffer.

Also, doctors consider patients to be fully responsible for their adherence. Patients, however, attribute responsibility to

outside factors in a high percent, considering that adherence is controlled by other people as well as themselves. It is important to understand this aspect that is essential in working towards an optimal adherence (7,8).

The role of a psychologist or counselor is crucial in dealing with this adherence. It is essential that the patient is evaluated from a psychological point of view and that every aspect of his/her expectations about ART is explored.

In order to assure adherence to the ART it is very useful to find common ground between the patient and the doctor. Building a healthy relationship is essential in monitoring the HIV positive patient and in encouraging adherence.

Education is important in every moment of the patient's life, in order to assure full assumption of responsibility, a key factor in adherence to ART.

CONCLUSIONS

In our research, we realized that, in order to assure adherence to the ART it is important to explore both the doctor and the patient's perspective and to find a common ground in building a healthy relationship. Both parties have the same main objective – to improve the patient's health status and quality of life. However, doctors see this objective reflected in the viral and immunological status, where as patients see it in psychological aspects and social integration. It is essential for both to realize the common direction their actions and expectations have, and to work together in achieving goals. The differences in perspective need to be addressed by both parties and it is essential to have support from a psychologist.

SPATTER CONTAMINATION IN DENTAL PRACTICES – HOW CAN IT BE PREVENTED? (Abstract): Infectious diseases endanger all dental personnel during treatment, especially when spatter and aerosols are produced. Therefore, there is a strong need for better infection control principles during all treatments. The purpose of this in-vitro pilot study was to measure the environmental spatter contamination through a fluorescence technique. Scaling was performed using different power-driven devices and high-volume evacuation combined with a newly developed cannula (PS), standard suction cannulas (STS) and saliva ejectors (CDS). **Material and methods:** One sonic (AIR) and two ultrasonic devices (TIG, VEC) were utilized to remove biofilm from 168 artificial teeth in a manikin head. Teeth were scaled for 120s supra- or subgingivally. The spatter contamination of an area of 1.5m2 around the manikin head was assessed. **Results and conclusions:** The contaminated area (%) was significantly different for the AIR (median [25th; 75th percentiles]: 2.5 [1.16; 6.05]) versus TIG (0.25 [0.18; 0.88]) and VEC (0.08 [0.06; 0.1]) ($p < 0.001$). Irrespective of the instrument, subgingival scaling led to a less contaminated area (0.18 [0.07; 1.05]) than supragingival scaling (0.34 [0.1; 2.24]) ($p < 0.001$). High-volume evacuation combined with STS (0.17 [0.07; 1.04]) and PS (0.18 [0.07; 1.14]) reduced the contamination similarly ($p=0.302$) and was more effective compared to CDS (1.01 [0.12-5.78]) ($p<0.001$; $p=0.002$). Beside the limitation of an in-vitro investigation, it can be conclude that only high-volume evacuation with an adequately calibrated cannula is capable of significantly reducing the amount of spatter contamination produced during power-driven scaling. **Keywords:** SPATTER, CONTAMINATION, DENTAL PRACTICES, SCALERS

A central part of the initial and supportive periodontal therapy (SPT) is the mechanical removal of supra- and subgingival plaque and calculus (1, 2). Suitable oscillating scaler systems can be divided into sonic and ultrasonic scalers. Such scalers are the major source of potential aerosol and spatter contamination in dental practices besides high-speed hand pieces (3-7), however with some differences between sonic or ultrasonic scalers (8). The reported resurgence of bacterial diseases such as tuberculosis (9) and the presence of other pathogenic organisms with the potential for airborne transmission causes increasing concern about aerosol contamination and minor air quality in dental offices (10-12). Capturing as much cooling spray as possible seems important since there is evidence for blood contamination in spatter produced by power-driven devices (13). Therefore, recent investigations analyzed

the infection risk through spatter in order to create a prediction model of the total number of bacteria. Thus a positive correlation between the number of decayed teeth and calculus as well as a negative correlation to preoperative rinsing with chlorhexidine was found (14). In addition to that, this pilot study looked at the use of a special new cannula combined with a high-flow evacuation system for the reduction of spatter during scaling with different sonic and ultrasonic scalers to give further recommendations for working safely.

MATERIAL AND METHODS

Manikin head and teeth test

The manikin head was equipped with periodontitis models (A-PB, Frasaco, Tettnang, Germany). The jaw model of upper and lower jaw, full dentition with permanent teeth (28 teeth without wisdom teeth) and the elastic gingiva mask in pink color (A-PB WOK/WUK, Frasaco, Tettnang, Germany) simulated periodontitis with advanced horizontal bone loss and isolated, deep vertical pockets. During the investigation, the root surfaces of eight test teeth (all first incisors and all first molars in both jaws; a total of 168 teeth resulting in 672 root surfaces) had to be cleaned either with a sonic or one of two ultrasonic devices. The test teeth show no furcation involvement or concavity of the root surface and the probing depths were 4-6 mm. No calculus was applied locally considering the fact that the primary aim of this study was to imitate the patient's treatment with power-driven devices during SPT to investigate the formation of liquid deposit and droplets. Therefore a maximum of two minutes was allowed for the instrumentation of one tooth (15). Badersten et al. (15) and our pre-trials had shown that this time span is sufficient for biofilm removal with instruments during SPT and did not restrict the work of a trained operator (16).

Instrumentation procedure

The three power-driven devices for sub-/supragingival scaling were randomly assigned to the three suction devices using a computer-generated table of random numbers. One sonic scaler AIR (Synea, W&H, Bürmoos, Austria) and two ultrasonic hand-pieces TIG (Tigon+, W&H, Bürmoos, Austria) and VEC (Vector, Dürr, Bietigheim-Bissingen, Germany) were used with slimline tips (P60 and P1, W&H, Bürmoos, Austria; P1, Dürr, Bietigheim-Bissingen, Germany). One experienced operator (C.G.) performed all study procedures during all 18 trial series; six trials for each of the two high-volume evacuation cannulas with a bore diameter of 12 mm (STS: standard suction cannula and PS: prophylaxis cannula; Dürr, Bietigheim-Bissingen, Germany) and six trials for a saliva ejector (Pluradent, Offenbach, Germany) with a bore diameter of three mm (CDS) (fig. 1). The operator wore black, nonabsorbent clothes and gloves. The camera was placed at a distance of 1.93 m from the ground above the manikin head from where a baseline picture was taken. For demonstrative purposes see Figure 2a: experimental setup under normal light conditions. Scaling was performed with the assigned sonic or ultrasonic unit for a standardized period of time of two minutes. During instrumentation the two different suction cannula as well the saliva ejector were used with a high-speed evacuation system (VAS 300 S, Dürr, Bietigheim-Bissingen, Germany) with a standardized suction volume of 300 ml/min and a depression of 180 mbar.

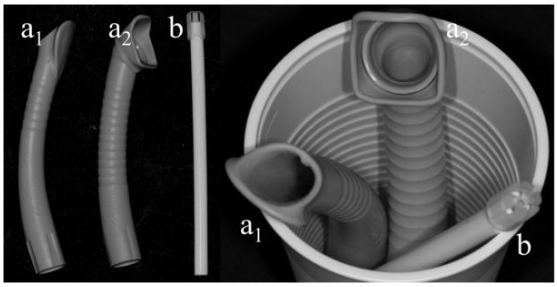

Fig. 1. The three tested cannulas; (a1) STS and (a2) PS as high-volume evacuation devices with a bore diameter of 12 mm and (b) a saliva ejector with a bore diameter of 3 mm (CDS). All of them were combined with a high-flow evacuation system.

Treatment room and visualization of spatter contamination

For the current investigation a treatment room at the Department of Conservative Dentistry and Periodontology in Kiel without any ventilation system was darkened and all surfaces 1.5m2 around the manikin head (see Figure 2a, red rectangle measuring 1.11m x 1.35m) were colored with matt black lacquer (Plasti Dip Deutschland GmbH, Aschaffenburg, Germany). To visualize the spatter, droplets and deposit during treatment, 50 mg/l fluorescein (Uranin, Niepötter Labortechnik, Bürstadt, Germany) was added to the water supply, which would fluoresce with bright orange color when exposed to ultraviolet light (UV-A, 350-370 nm). Therefore not only deposited fluorescing material on all black surfaces but also non-deposited airborne particles floating between the floor and the camera were visible in the photographs (fig. 2b).

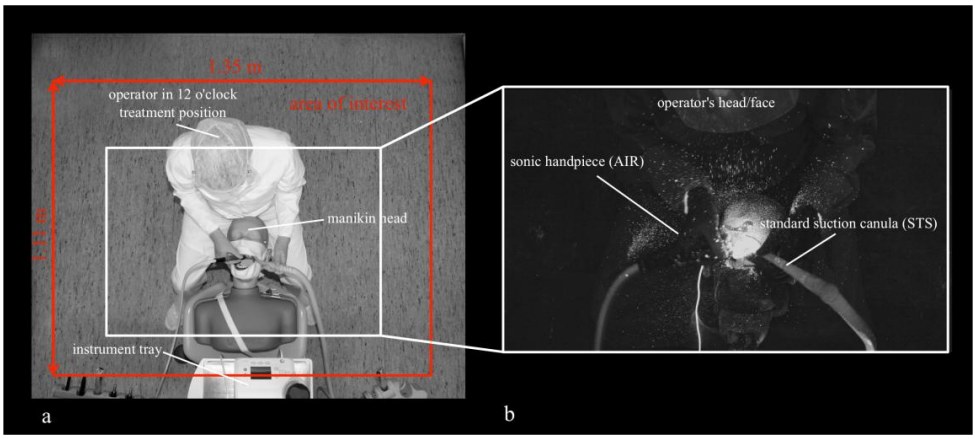

Fig. 2. The treatment room with the dental unit and the operator in 12 o´clock treatment position. (a) For demonstration purposes: experimental setup under normal light conditions and no black lacquer coverage of all surfaces/black clothes. The assessed area of interest of 1.5 m2 is marked by red frame. (b) Photo taken under experimental conditions: Enlargement of framed area after 120 s of scaling the first incisor in the right maxilla with sonic instrument AIR and standard suction cannula STS.

Plan metric evaluation of spatter contamination

The evaluation of the contaminated area with spatter and droplets was plan metrically assessed. To enable standardized evaluation through the camera, the manikin head was placed over fixed marks on the ground in the treatment room for a reproducible position (fig. 2). Due to the downward facing camera position, the surface directly underneath the manikin head wasn't measurable (fig. 2). Using a camera (Canon, EOS D30, Tokyo, Japan) with a 18 – 55 mm zoom (EFS, Canon, Tokyo, Japan), eight photographs of the work area were recorded (every 15 seconds during two minutes of instrumentation for each tooth). Focus and position were checked on a monitor (HP Compaq LA2205wg, Hewlett-Packard GmbH, Böblingen, Germany) and the photographs then transferred to the evaluation program by means of digitizer software (NIH Image, Version 1.41, National Institutes of Health, Bethesda, USA). To evaluate the individual aerosol and spatter distribution at every point of time during scaling, the program (Excel 2013, Microsoft Corporation, Redmond, USA) was set up to draw standardized data masks with quadrangle arrays of 12 x 12 pixel (4.6 mm x 4.6 mm), which assisted in including the determined area in the evaluation. The percentage of the spatter distribution area was calculated via selective marking of the contaminated areas from the base area of 69984 quadrangle arrays through simple scoring of positive or negative areas, in which the bright orange color of the marker was seen. Due to the absence of measurement of the fluorescence intensity, only a quantitative analysis of the deposit distribution was possible.

In order to determine the amount of water routinely used, the flow of water during one minute was measured using a graduated cylinder. Prior to each trial, the operator adjusted the coolant flow for the sonic and ultrasonic scaler to the clinically ideal level of 25-30 ml per minute as recommended in literature (17). The actual amount of cooling water was measured during all trials.

Statistical analysis

Statistical analysis was performed using SPSS (SPSS Statistics 20, IBM, Chicago, IL, USA). The assumption of a normal distribution of data was checked by the Shapiro-Wilk test. Differences between the operator's localization, suction devices and instruments were analyzed using the Kruskal-Wallis non parametric ANOVA. Post hoc tests were afterwards performed by the Mann-Whitney-U test, whereby the significance level was adjusted after the Bonferroni Method (α divided by the number of performed tests). Deviation within teeth was calculated by the Wilcoxon test. Differences in coolant flow measurements were assessed using the t-test. All statistical tests were two-sided and used a significance level of $p=0.05$.

RESULTS

High-volume evacuation with PS and STS versus saliva ejector CDS

In regard to the suction devices the Kruskal-Wallis test showed significant results ($p<0.001$). The high-volume evacuation systems combined with the two cannulas STS (0.17 [0.07; 1.04]) and PS (0.18 [0.07; 1.14]) showed a similar reduction of the aerosol ($p=0.302$). Compared to the saliva ejector CDS (1.01 [0.12-5.78]) they were more effective ($p<0.001$ and $p=0.002$, respectively) (fig. 3). After subdivision in supra- and subgingival scaling we saw a favourable trend for subgingival scaling, due to the Bonferroni adaption STS and PS now differing significantly for subgingival (0.07 [0.03; 0.9] and 0.18

[0.07; 1.06]; p=0.029). Nevertheless, when performing supragingival scaling there existed no significant differences in spatter formation (tab. I).

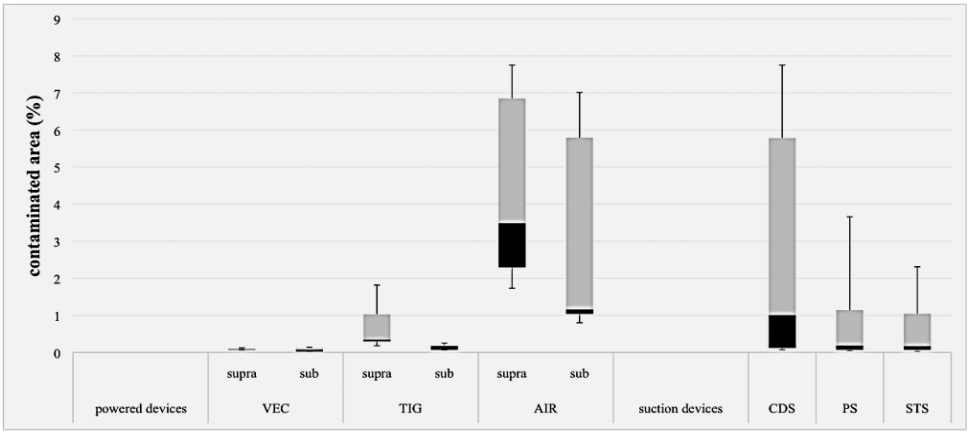

Fig. 3. Illustration of the contamination area (whiskers show minimum and maximum data) divided into the different power devices AIR, TIG and VEC as well as into the different evacuation methods STS, PS and DTS.

TABLE I

Area of contamination (median [25th; 75th percentiles]) divided by the different power-driven devices: sonic scaler (AIR) and two ultrasonic scalers (TIG and VEC) as well as by the high-volume evacuation systems combined with the standard cannula (STS) and a newly developed cannula (PS) and the conventional saliva ejector (DTS).

Power-driven device		Contaminated area (in total)	Contaminated area (supragingival scaling)		Contaminated area (subgingival scaling)	
	AIR	2.5 [1.16; 6.05]	3.49 [2.29; 6.85]	p<0.001	1.16 [1.04; 5.79]	p<0.001
	TIG	0.25 [0.18; 0.88]	0.34 [0.3; 1.03]	p<0.001	0.18 [0.07; 0.19]	p<0.001
	VEC	0.08 [0.06; 0.1]	0.09 [0.07; 0.09]	p<0.001	0.07 [0.03; 0.11]	p<0.001
Suction device						
	STS	0.17 [0.07; 1.04]	0.31 [0.09; 2,01]	p=0.993	0.07 [0.03; 0.9]	p=0.029
	PS	0.18 [0.07; 1.14]	0.29 [0.09; 3.22]	p=0.155	0.18 [0.07; 1.06]	p<0.001
	CDS	1.01 [0.12-5.78]	1.04 [0.1; 5.93]	p=0.096	0.23 [0.12; 5.79]	p<0.001
Localization						
	Maxilla		0.44 [0.1; 2.36]	p=0.874	0.23 [0.06; 0.62]	p=0.155
	Mandible		0.26 [0.12; 1.98]		0.11 [0.07; 1.1]	
	Incisors		0.47 [0.11; 2.73]	p<0.001	0.15 [0.06; 1.13]	p=0.926
	Molars		0.27 [0.11; 1.64]		0.14 [0.07; 1.02]	
Maxilla	Incisors		0.57 [0.1; 2.67]	p=0.604	0.22 [0.03; 0.59]	p=0.008
	Molars		0.38 [0.08; 1.84]		0.21 [0.05; 0.41]	
Mandible	Incisors		0.35 [0.12; 2.59]	p=0.339	0.11 [0.07; 1.21]	p=0.217
	Molars		0.24 [0.14; 1.43]		0.11 [0.07; 0.99]	
Treatment position 8-9 o'clock			0.25 [0.09; 1.68]	p<0.001	0.11 [0.04; 0.63]	p<0.001
Treatment position 10-12 o'clock			0.49 [0.12; 2.68]		0.21 [0.1; 1.32]	

Statistical significance was verified with the Kruskal-Wallis test and followed by post hoc Mann-Whitney-U test (operator's localization, suction devices and instruments) and by the Wilcoxon test (teeth). For better understanding we left out the results from the Kruskal-Wallis ANOVA.

Power-driven devices

The size of the contaminated area was significantly different during supragingival scaling for the three different scalers (all groups $p < 0.001$): AIR, TIG, VEC (fig. 3). The same results were found while performing subgingival scaling (all groups $p<0.001$) (fig. 3). Irrespective of the power-driven device used, subgingival scaling led to a lower contaminated area in percent (median [25th; 75th percentiles]: 0.18 [0.07; 1.05]) compared to supragingival scaling (0.34 [0.1; 2.24]) ($p < 0.001$).

Spatter contamination and treatment position

A significant difference in the contaminated area was found concerning treatment positions regardless of the used instrument or the suction device (all groups $p<0.05$). The contamination in 10-12 o'clock treatment position was higher than in other treatment positions. The highest contamination was generated when scaling the upper incisors supragingivally (0.57 [0.1; 2.67]). During supragingival instrumentation and evacuation there were significant differences between incisors and molars to be found ($p<0.001$). For subgingival scaling the results were not significant ($p=0.926$). There were no significant differences seen for neither mandible vs. maxilla nor for supra- vs. subgingival scaling ($p=0.874$).

Coolant flow

The mean coolant flow measured during all six trials varied from 27.7±2.7 ml (TIG), 30.1±3.5 ml (AIR) to 30.5±1.9 ml (VEC) per minute. During these trials the loss of coolant medium, potential for generating spatter and aerosols, was without significance ($p=0.378$) for TIG (2.7±1.4 ml/min) and VEC (2.4±1.5 ml/min) except for sonic scaler (AIR). The use of sonic scaler AIR resulted in an increased loss of 4.7±2.4 ml/min ($p=0.054$). The percentage of evacuated coolant (amount of evacuated coolant medium x 100/amount of used coolant medium) was 47.0±14.8 for the STS and 44.3±16.1 for PS ($p = 0.873$) and was significantly less by 6.3±7.8 for the CDS ($p = 0.001$).

DISCUSSION

Previous research has shown that ultrasonic and sonic scalers, are routinely established and used in modern prophylaxis and periodontal treatment (18, 19), but with the disadvantages to generate spatter and aerosol (8, 20-22). Both can contain airborne or blood-borne pathogens (23) and may cause various infections such as legionellosis, tuberculosis or hepatitis (24-26) or other more insidious problems like watery eyes, running noses, headaches or itchy skin (27). Several authors strongly suggest that dental staff using power-driven devices for scaling may be at a greater risk than other healthcare workers (7, 8, 27). Nevertheless, no clinical study has so far shown a direct cause-effect relationship between bacteria-contaminated spatter or aerosols and infections. It seems indisputable that spatter produced by ultrasonic or sonic scalers is greatest in the immediate vicinity of the patient. But an alteration of bacterial contamination in a distance of up to three meters from the patient can still be recognized (24), particularly when using airpolishing equipment (28). However, it is mostly assumed that splashes of water droplets move around 1.2 to 1.8 meter from a patient's oral cavity (6-8, 29, 30). Therefore, and due to the limitation of our operating room, the area of interest for a single operator was defined as a maximum of 1.11 m x 1.35 m. The generated dispersion in this current investigation given in % of the

defined area seems very small. This is not actually the case since the spatter contamination of e.g. 1.01% during the use of CDS alone caused a contaminated area of at least 0.02m2. This adds to 123 x 123 mm (15150 mm2), which equates to the entirely coated palms of the operator, being completely polluted with potentially infectious spatter.

However, through the use of special aerosol reduction devices some investigators have decreased the contamination by nearly 90-97% (31, 32). But those reduction systems are not very common and the spatter development during air polishing is not comparable to those of sonic-/ultrasonic scalers. Jacks (31) discussed that the negligence of the operator to use such special reduction systems could be a result of the difficulty to handle two bulky instruments simultaneously. This corresponded with our observations during the use of the newly developed cannula PS, which tended to be too cumbersome to use. The anticipated improvement in the standard cannula SPS, therefore, failed.

Irrespective of the simple and inexpensive methods for the control of dental aerosols and spatter already available (33), dentists do not apply those methods mostly because of low awareness of health risks, working habits and economic factors (7). Due to the experimental setup of our investigation without air collection, it was difficult to find similar results for aerosol contamination in the studies we cited, which made use of real time aerosol monitoring (grams/cubic meter). It can be assumed that there were inspirable particles emitted due to scaling, which can be termed as aerosols. Nevertheless our study technology only measured spatter, droplets, deposits and non-deposited airborne particles. Therefore, we added the effectiveness of suction during scaling [ml] to discuss potential coolant medium for spatter. A similar effectiveness for STS and PS of nearly 50% and significant result of 6% with a saliva ejector could be found, corresponding to the results of Jacks (31). The results re-emphasized the statement that a lot of coolant medium is potentially present to generate aerosol (fig. 4). In a separate experiment we were able to visualize the spatter production induced through the tip movement during the first two seconds for an area of 0.50 x 0.80 m (fig. 5). According to Timmermann et al. (34), piezoelectric devices, as a result of their linear tip movement (35), should produce less spatter than sonic scalers with almost circular tip movement and a greater amplitude (36). This was in accordance to the spatter production of the two piezoelectric devices in this current investigation, which was significantly lower and more or less target-oriented compared to the sonic scaler (VEC 0.08% and TIG 0.25% versus AIR 2.5%) (fig. 6). According to this, one should carefully consider the choice of instruments, especially when treating potentially infectious patients, and if necessary opt for the use of an ultrasonic scaler.

Due to the higher risk of generating spatter, especially during the use of sonic scalers, only high-speed evacuation systems with a standardized suction volume of around 300 ml/min, as employed in the current investigation (VAS 300 S, Dürr, Bietigheim-Bissingen, Germany), should be used. This recommendation is similar to other studies (37, 38) and shows that the only efficient method for controlling contaminated spatter is the use of a large-diameter high-volume evacuator, instead of e.g. reducing the cooling water supply (28). Heat is produced during operating mode for all power-driven devices (17, 39) and only using cooling medium minimized heat gen-

eration to physiologically tolerable levels (39). Consequently, the necessary cooling during root instrumentation leads to the reality that even small amounts of irrigation can result in potentially contaminating spatter (8). Our results also show that an entire elimination is impossible and, therefore, instrumentation of infectious patients with hand instruments may be recommended (40). Since a salivary ejector can only remove a small volume of air, it's sole use proves ineffective to remove aerosols and spatter (31, 32). However, the use of the special newly developed cannula (PS) for high-volume evacuation in our investigation seems to neither improve spatter reduction (0.18% contaminated area) nor improve the effectiveness of suction (44%) compared with a standard cannula STS (0.17% contaminated area, 47% effectiveness of suction).

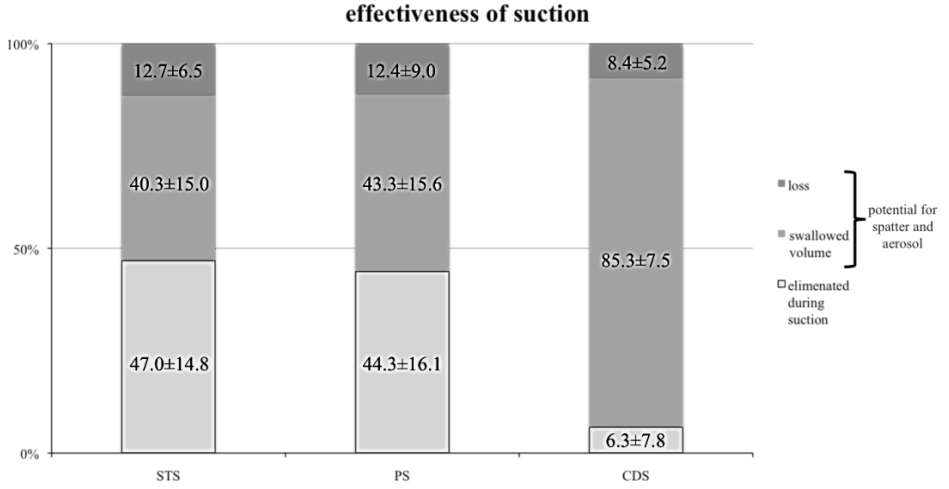

Fig. 4. Illustration of the effectiveness of cooling medium evacuation (%) divided by the three different evacuation methods: standard cannula (STS), the newly developed cannula (PS) and the conventional saliva ejector (CDS).

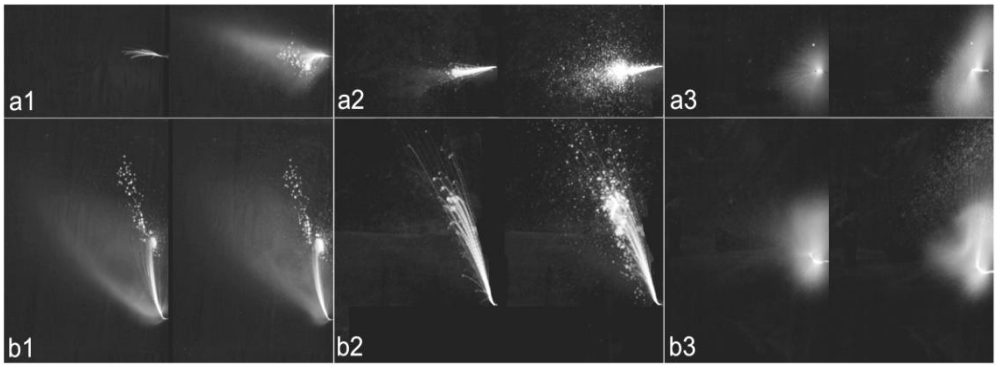

Fig. 5. Spatter and aerosol production right after start and after 2s of tip movement using the two ultrasonic scalers (a/b1: TIG, a/b2: VEC) and one sonic scaler (a/b3: AIR). The upper pictures (a1-a3) show the tip movement in vertical direction and the lower pictures (b1-b3) in horizontal direction.

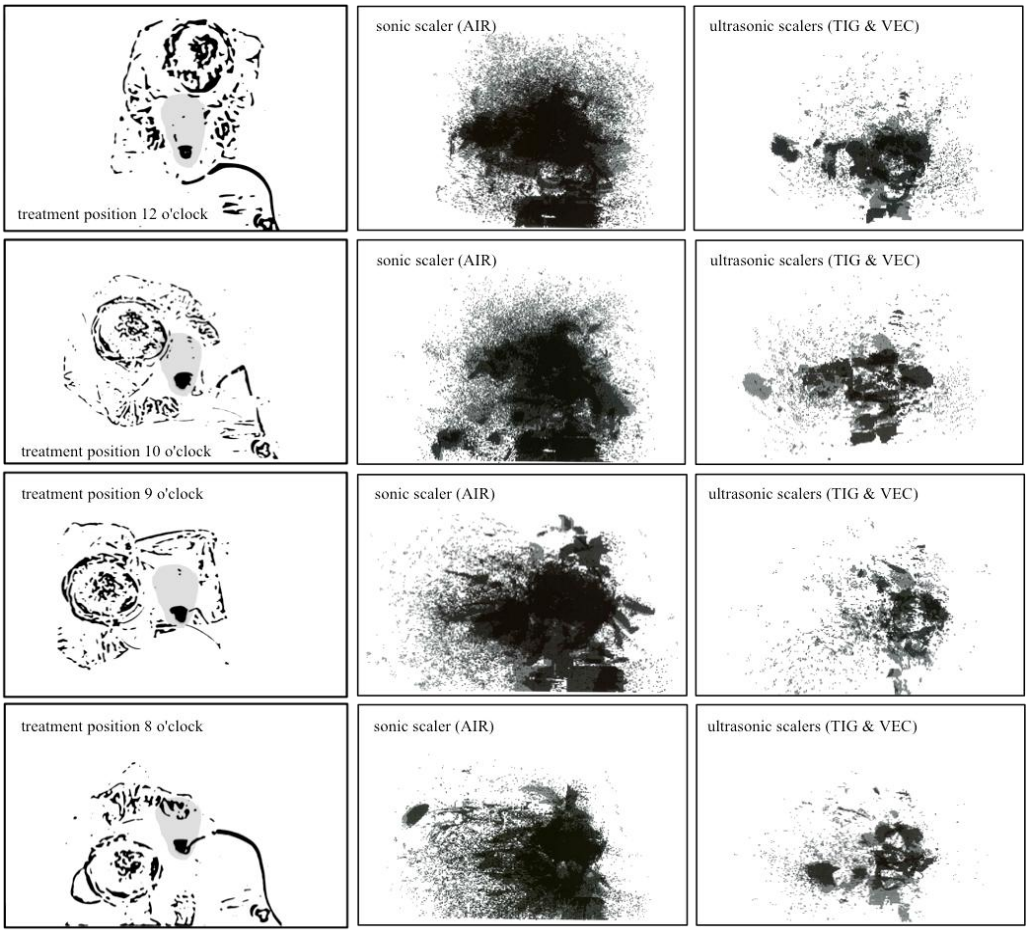

Fig. 6. Area of contamination in the treatment room (measured area: 1,11 m x 1.35 m) according to the treatment positions 8, 9, 10 and 12 o'clock as a summation of 18 trials with a sonic device (AIR) and 18 trials for each of the two ultrasonic devices (TIG and VEC). Due to the identical characteristics, the two ultrasonic scalers were analysed together for this visualization. All three different evacuation systems (STS, PS and CDS) were used. The gradation of the spatter was as follows; black was used when the area was contaminated in all 18 trials, dark grey was used when the area was contaminated in 8 to 17 trials and light grey was used when the area was contaminated in 1 to 7 trials.

Along with the already discussed variables such as instruments and type of suction, the part of the dentition that is being worked on as well as the treatment position greatly influence the occurrence and spreading direction of spatter. In this context, the lips can work as a protection visor, when working from a 12 o´clock position (41). The results of our investigation showed a different picture for the risk of contamination also in this treatment position, especially during the use of the sonic scaler with significantly more spatter production (fig. 6). It could be possible that a

single operator is often unable to work the suction from buccal and therefore spray rebound is unavoidable even from a 12 o'clock position. Another fact to discuss may also be the characteristic of the less flexible lips due to the rubber material and the maximum opening of the manikin head´s mouth. However, the use of the PS as well as the STS seems cumbersome from a subjective point of view.

One limitation of this study as well as other studies was the 2D visualisation of the treatment room (fig. 2) (41). Only the horizontal dimension of the area of interest was photographically documented during treatment. The spatter, which settles on vertical surfaces such as furniture of the room, clothes, the face or face guard, is only conditionally viewable. Even the modified technique, with a fluorescein solution we used to visualize spatter and droplets, could not solve these problems, even though it seemed that the spots produced on horizontal areas could be evaluated more accurately compared with the erythrosine (13). Another aspect that has to be mentioned is that the size of the spatter produced by the sonic and ultrasonic devices seemed different (fig. 5), but the sensitivity of the used detection method failed to measure this. The analysis of the difference between the used and the sucked in volume of cooling medium cannot solve that problem, nevertheless the amount of lost cooling water that can potentially form spatter as well as aerosols was shown (fig. 4).

Despite the limitations of the research design, it can be said that by using the opening of the mouth as a shield, a reduction of the risk of contamination for the posterior teeth can be assumed from all treatment positions. Still a higher risk of infection for the dentist in treatment positions like 12 o´clock for the anterior teeth has to be discussed. It seems that in the treatment position behind the patient's head the face of the operator, eyes and nose are most important for transmission of infections (42), as well as his chest area (30, 43) are the most contaminated area. Therefore it is recommended to use protective means like glasses, masks and especially in treatment positions between 10 and 2 o'clock as a protective shield, which offers the greatest protection in this area. Furthermore, the use of pre-procedural rinsing with an antiseptic mouthwash may be of value in protecting patients and dental professionals due to the reducing effect on the microbiology flora of the oral cavity (43-48).

CONCLUSIONS

The risk of spatter contamination of the area next to the patient's mouth during scaling increases with the use of sonic versus ultrasonic device as well as with the use of saliva ejector versus high-volume evacuation devices. Also the treatment position of the operator and the region of the mouth that is being treated can influence the generation of potentially infectious spatter. It is therefore strongly advised to use high-volume evacuation devices and to wear a visor during treatment in all positions behind the patient's head to protect the face of the operator. Since even under ideal conditions spatter cannot be avoided, it is strongly recommended to follow the common suggestions for protection during dental treatment: use of eye protection, masks, gloves, clothes coverage and rinsing the oral cavity of a patient pre-procedural with antiseptic mouthwash (7, 12, 33, 46, 48).

NEWS

RELATIONSHIP BETWEEN OBESITY AND ORAL DISEASES

The aim of a study realized by a group of researchers from University of Benin, Nigeria was to determine the relationship between obesity and periodontal status and dental caries experience of a group of nigerian dental patients. Participants were selected from patients attending dental outpatient clinics of the University of Benin Teaching Hospital, Benin City, Nigeria. Their weight and height were measured and body mass index (BMI) estimated in kg/m^2, gingival health assessed using bleeding on probing index, oral hygiene estimated using the simplified Oral Hygiene Index (OHI-S), periodontal health estimated using the Basic Periodontal Examination (BPE) and caries experience was estimated with the Decayed, Missing, Filled teeth (DMFT) index. A few participants (3.8%) were underweight, 52.6% fell within the normal BMI range, 28.2% pre-obese, 12.2% obese class I and 3.2% obese class II. The mean OHI-S score was 2.16 ± 1.13 among the overweight participants and 2.05 ± 1.13 among those who are not (P = 0.543). The mean DMFT score was 3.03 ± 4.25 among the overweight participants and 2.32 ± 3.01 among those who are not (P = 0.223). Sixty-five percent of participants with BPE score of 0, considered to signify periodontal health, had normal BMI while all the participants with the worst BPE score recorded belong to the obese 1 group (P = 0.070). The binary logistic regression revealed that the likely predictor of gingival bleeding in the study is BMI between 35.0 and 39.9 (obese class 2) (P = 0.046, odds ratio = 0.07, 95% confidence interval = 0.01-0.96). It can be concluded that there was no statistically significant relationship between obesity and periodontal status and dental caries experience in the studied group of dental patients. Increased body mass index may however be a predictor of gingival bleeding (Sede MA, Ehizele AO. Relationship between obesity and oral diseases. *Niger J Clin Pract*, 2014 ; 17 (6) : 683-690)

UTILITY OF AUTOPSY IN MEDICAL EDUCATION - STUDENTS' OPINIONS AND ATTITUDES

UTILITY OF AUTOPSY IN MEDICAL EDUCATION- STUDENTS' OPINIONS AND ATTITUDES (Abstract): Autopsy has been for centuries part of medical education, providing benefits to medical students in terms of knowledge, skills, and development of respect, empathy and compassion. **Aim:** To evaluate the utility of autopsy in medical education based on the opinions and attitudes of medical students. **Material and methods:** A questionnaire was applied to 219 medical students. The answers were grouped according to two main themes: the utility of autopsy in medical education and students' attitudes toward autopsy. **Results:** Most of the respondents considered that autopsy is useful to society, medical practice and medical education. On average, participants felt "moderately uncomfortable" on exposure to the first autopsy. **Conclusions:** Our study indicates the need for medical education to emphasize the utility of autopsy in the medical practice. Extracurricular activities to deepen the medico-legal knowledge and skills would be beneficial for the students who are particularly interested in this specialty. It is also necessary to take into account the possible negative psychological reactions of the students caused by the first exposure to autopsy and identify adequate methods to solve them. **Keywords**: AUTOPSY, MEDICAL EDUCATION, MEDICAL PRACTICE

Autopsy has been for centuries an important educational tool (1, 2) and the findings during autopsies allowed the achievement of many of the modern medical knowledge (3). Autopsy has many educational roles. It facilitates understanding of the clinical and pathological, physiological and anatomical correlations, improves the observation and communication skills, and provides the students the opportunity to address specific topics, such as: death certificate, violent death, attitudes towards death (4, 5).

However, the use of autopsy in medical education is decreasing due to the progressive change of university curricula, the emergence of teaching alternative technologies, such as video projections, and the overall decrease in the number of autopsies due to the legal, bureaucratic, financial or religious barriers (6, 7). Unfortunately, many times alternative technologies fail to match the immediate impact of exposure to autopsy (6), making less likely that the clinicians who did not attend any autopsy to become supporters of autopsy (4, 5) or identify the need for

this examination (8).

Forensic Medicine is taught at the Iasi Faculty of Medicine in the sixth year of studies. During the practical activity, the students attend five autopsies, and become familiar with the legal procedures, technical aspects of autopsy, death certificate, and ethical issues which stem from the respect for the deceased and his/her family. During the practical activity students are not required to participate effectively in the autopsy but only to attend and learn the procedure.

MATERIAL AND METHODS

The aim of our study was to analyze the opinions of the medical students about the utility of autopsy in medical education and practice. We also sought the respondents' attitudes toward autopsy, i.e. their reaction to the first autopsy and the degree to which they accept and recognize the value of postmortem examination.

We used a quantitative methodology applying a 14-items questionnaire with a 6-point Lichert scale (1- disagree to 6- always agree). The data were analyzed with *SPSS* using the factorial analysis and Mann–Whitney–Wilcoxon test.

The study group comprised 219 sixth year medical students who completed the Forensic Medicine course. They answered the questions anonymously and received no financial compensation for their participation. Before completing the questionnaire, the aim of the study and the questionnaire sections were explained and the subjects were asked to give their written consent to participate in this study. The study was approved by the Research Ethics Committee of the "Grigore T. Popa" University of Medicine and Pharmacy.

RESULTS AND DISCUSSION

The mean age of the participants was 24.56 ± 0.98 years (range 23 ÷ 29). Gender distribution showed a preponderance of females (139; 63.5%). The majority of the participants were of Romanian nationality (95%), most were Orthodox Christians (92.2%), and 49.3% declared themselves religious persons.

Most of the participants were first exposed to autopsy in the sixth year, during the Forensic Medicine practical activity (196-89.5%). Some of the students were first exposed to autopsy during the first five years of studies during the Anatomy or Pathology classes (tab.I, II).

To investigate the influence of various sociological characteristics we applied the Mann-Whitney-Wilcoxon test (tab. III).

TABLE I

Centralization of the answers from participants

Question	N	Median (quartile interval)	Average ± Standard deviation	Median answer
1. Students should attend more autopsies	219	3 (2÷4)	2.8±1.39	sometimes agree
2. Autopsy will be useful to my future medical activity	219	4 (3÷5)	4.07±1.26	often agree
3. During autopsy I have learned many things that I will use in the medical practice	219	4 (3÷5)	4.11±1.18	often agree
4. Autopsy should be a compulsory part of academic curriculum	219	5 (4÷6)	4.64±1.44	very often agree

Question	N	Median (quartile interval)	Average ± Standard deviation	Median answer
5. Students should actively participate in autopsy	219	3 (2÷4)	2.97±1.53	sometimes agree
6. Autopsy is useful for the progress of medicine	219	6 (4÷6)	5.1±1.14	always agree
7. Autopsy is contrary to religious beliefs	219	1 (1÷3)	1.96±1.25	disagree
8. Exposure to autopsy has influenced my perspective on clinical activity	219	3 (1÷4)	2.81±1.53	sometimes agree
9. I would accept to be autopsied after death	219	5 (3÷6)	4.33±1.85	very often agree
10. I would consent for a deceased close relative to be autopsied	219	5 (3÷6)	4.61±1.64	very often agree
11. Afterlife exists	218	3 (2÷6)	3.72±1.98	sometimes agree
12. Participation to autopsy made me wish to become a forensic pathologist	219	1 (1÷2)	1.71±1.25	disagree
13. Autopsy is useful to society	219	6 (5÷6)	5.17±1.05	always agree
14. Reaction at the first autopsy	218	3 (2÷3)	2.6±1.05	moderately uncomfortable

We grouped the respondents successively by gender (male/ female), religiousness (Yes / No), the preference for Forensic Medicine specialty (answers "very often disagree" and "always agree" to question 12), nationality (Romanian/ other), religious affiliation (Christian Orthodox/ other religion), and discipline where the participants were first exposed to autopsy (forensic medicine/ another discipline).

I. Utility of autopsy in medical education

Most of the participants considered that autopsy is useful to society and progress of medicine (”always agree”). They also considered that autopsy should be part of the academic curriculum (”very often agree”), a lower level of agreement being expressed by the female participants ($p = 0.024$). The students who acknowledged the utility of autopsy for the progress of medicine agreed with its educational utility and considered that it should be part of the academic curriculum.

The results of other studies also emphasize the educational role of autopsy. Autopsy provides knowledge in many medical fields and facilitates the development of a proper behavior towards the patients and their families (1). Khoo (9) shows that students believe that autopsy is a useful and beneficial experience that should be available to all students. In the study by Ekanem and Akhigbe (10) the majority of students agreed that autopsy is an important educational tool and students should be encouraged to watch and actively participate in this procedure.

The participants in our study partially agreed (”often agree”) that autopsy is useful to their medical practice. However, to a lesser extent they felt that attending an autopsy influenced the way they relate to clinical activity (”sometimes agree”), possibly due to a greater awareness of the risks of medical profession, legal risk included.

Benbow (1) showed that a sizeable proportion of students considered autopsy valuable to the medical practice. In the study by Khoo (9), the participants admitted that attending an autopsy allowed them to reflect on death and made them more prepared to accept patient death.

Most students participating in our study attended and watched autopsies, without being actively involved in the procedure (99.1% witnessed; 0.9% worked effective-

ly). To a lesser extent ("sometimes agree"), they believe that medical students should actively participate in autopsy. We found a statistically significant trend in favour of the active participation in autopsy from students who were first exposed to autopsy during the first five years of studies ($p = 0.032$).

In a study by Conran (11), most students considered that autopsy should be a compulsory part of the medical education, but only a few wanted autopsy on themselves. Khoo (9) found that the students showing interest in actively participating in autopsy, believed that this experience was likely to bring them real benefits.

The participants in our study attended on average six autopsies. Only 56 respondents felt that the students should attend more autopsies ("sometimes agree") assessing that the optimum number of autopsies would be 10 ($8 \div 10.5$). The foreign students advocated to a greater extent for an increased number of autopsies ($p = 0.004$), which may suggest their greater interest in the practical aspects of medical education. Generally, the preference to participate in (and perform) more autopsies is accompanied by a greater recognition of the utility of autopsy in clinical activity and an interest for Forensic Medicine specialty.

Ekanem and Akhigbe (10) found that 69.2% of the participants in their study attended 6- 15 autopsies and 57% of the participants considered that the number of autopsies was enough; however 74% of the participants believed that the students should be encouraged to watch and effectively participate in more autopsies. Sanner and Charlton *et al.* (12, 13) showed that the students are aware that attending a single autopsy is not enough.

II. Students' attitudes toward autopsy

On average the participants in our study felt "moderately uncomfortable" on the first exposure to autopsy. Discomfort was reported to a greater extent by the female participants ($p = 0.003$) and by the religious persons ($p = 0.002$).

The students may experience moderate to serious psychologic reactions on their first exposure to autopsy (14). In the study by Benbow (1), 20% of students acknowledged the utility of autopsy but found it unpleasant and considered they should have been prepared psychologically before the first exposure to autopsy.

It is well recognized that the students should be psychological prepared before attending the autopsy in order to avoid unpleasant reactions and to take advantage of the benefits of attending such a procedure (13, 15, 16). However the potential negative psychological reactions caused by exposure to autopsy is usualy neglected in medical education although autopsy may raise "emotional feelings with regard to human mortality and dignity" (17). He Miao-Xia *et al.* (18) observed that students, after getting over the psychological impact of the first exposure to autopsy became calm, took notes, and focused without getting involved emotionally.

To a large extent ("very often agree") the participants in our study would agree to an autopsy on themselves or a deceased close relative. These findings correlate with the recognition of the social and medical utility of autopsy.

Students who were exposed to autopsy in the first five years of studies years showed less objection to their own autopsy ($p = 0.033$) or the autopsy of a deceased close relative ($p = 0.041$). On the other

hand, the religious persons wanted to a lesser extent an autopsy on themselves (p <0.001) and a close relative (p = 0.005) than the non-religious participants.

Other studies showed that most students would agree with their own autopsy (12, 17), but the thought of it made them feel uncomfortable (12). Khoo (9) found that only 34.1% of the students would agree with an autopsy on themselves or a close relative, but 72.9% would request an autopsy on their patients if necessary. Verma and Benbow (2, 15) found that many students, after attending an autopsy felt stressed knowing that a close person underwent a procedure which ”mutilates the body".

Most participants in our study did not consider autopsy contrary to their religious beliefs. No statistically significant differences were found between religious and non-religious subjects in this respect. This result is consistent with other studies that concluded that generally, religious beliefs are not valid reasons to deny an autopsy because religion does not prohibit autopsy *per se* (9, 19).

We found a partial agreement (”sometimes agree”) on the belief in afterlife. Females (p = 0.055) and religious persons (p = 0.002) agreed to a greater extent that afterlife exists. The respondents who endorsed the existence of afterlife and the conflict between religious beliefs and autopsy reported uncomfortable feelings on the first exposure to autopsy and would not pursue a career in Forensic Medicine.

Williams *et al.* (20) consider that belief in afterlife is a strategy chosen by 40% of medical students and resident physicians to deal with the death of their patients and relatives.

Most of the participants in our study believed that attending an autopsy did not instill the desire of becoming forensic pathologists. We found that the attitude toward autopsy of the students who consider becoming forensic pathologists is generally positive but we did not identify any significant differences between them and their colleagues in terms of gender, religiousness, or the number of autopsies attended. Similarily, Papadodima et al. showed that the students who wish to pursue a career in Forensic Medicine got involved more actively in autopsy but did not identify different characteristics in terms of age, gender, religious belifs, reactions, emotions, attitudes, and lifestyle compared to the rest of their colleagues (14).

CONCLUSIONS

The results of our study show that the students recognize the utility of autopsy for society and medical practice. They also consider that autopsy is an important educational tool. To a large extent, the respondents felt that the number of autopsies provided currently in the curriculum is sufficient and that it is enough for them to watch the procedure without being effectively involved. However, some students considered that attending more autopsies and the hands-on experience are beneficial for their medical education. For these students it would be useful to organize extracurricular activities that would allow them to deepen their knowledge and practical skills in this specialty.

Although students' attitudes toward autopsy are generally positive, on average participants stated that they felt moderately uncomfortable on their first exposure to autopsy. This result supports the fact that the possible negative psychological reactions caused by the first exposure to autopsy should be taken into account, and effective

ways of managing them, such as debriefing or preparatory sessions need to be used.

It would also be useful to mainstream Forensic Medicine among other specialties both conceptually and practically so that the students can perceive autopsy as a part of medical practice and develop a positive attitude toward postmortem examination.

PREDICTORS OF POSTSURGICAL STRESS AMONG CARDIAC PATIENTS

Lavinia Maria Pruteanu
Universitatea „Petre Andrei" din Iasi

PREDICTORS OF POSTSURGICAL STRESS AMONG CARDIAC PATIENTS (Abstract). **Aim:** To explore the role of stress vulnerability, dispositional optimism, fears of surgery and negative affective disposition in prediction of postsurgical stress among cardiac patients who underwent heart surgery. **Material and methods:** The sample included 60 cardiac patients (39 males and 21 females, aged 58.50±10.97 years). All patients completed two sets of standardized questionnaires. Before surgical intervention, stress vulnerability, dispositional optimism and negative affective disposition were measured with N6-Scale (from NEO Personality Inventory–Revised Form), Life Orientation Test-Revised Form and Mental Health Index-5, respectively. Fear of surgery among patients was measured with an 8-item questionnaire designed for the current study. After intervention, patients completed a short postsurgical data form along with the Perceived Stress Scale. **Results:** There was no significant difference in postsurgical stress between the female and male cardiac patients ($t = 0.96$; $p = 0.34$). A similar result was obtained when the presence/absence of postsurgical complications was considered as an independent variable ($t = 1.30$; $p = 0.19$). As expected, a higher level of postsurgical stress was associated with higher stress vulnerability, surgery-related fear, negative affective disposition, and with a lower dispositional optimism score. Moreover, stress vulnerability and negative affective disposition were significant predictors of postsurgical stress. **Conclusions:** Cardiac patients who are prone to stress and negative affective disposition are also at higher risk for postsurgical stress. On its turn, this psychological condition interferes with time and quality of postsurgical recovery. A careful assessment of psychological condition along with counseling before surgical intervention is needed in order to reduce the risk of postsurgical stress and improve medical recovery in cardiac patients. **Keywords:** CARDIAC PATIENTS, STRESS VULNERABILITY, DISPOSITIONAL OPTIMISM, FEAR OF SURGERY, NEGATIVE AFFECTIVE DISPOSITION, POSTSURGICAL STRESS

Surgery is a stressful life event which triggers many physiological, cognitive, and emotional responses among patients due to certain personality traits (i.e. dispositional optimism, emotional instability, confidence in the ability to control postsurgical course of the disease etc.), patient social network (i.e. the level of emotional and social support) or disease-associated clinical characteristics (1). The social, emotional, and cognitive consequences of a surgical intervention have also drawn the attention of professionals and researchers in medical care and social services. The psychological (pre- and post- surgical) state of patients is due to recurrent afflictions, post-surgery complications, mortality rate, and also certain recovery quality indicators (i.e. the

psychological and physical well-being, or the outlook on quality of life) (2).

Usually, the pre-surgical stage of a cardiac intervention is stressful for the patient, as well as for his/her family (3), while recovery is physically and psychologically challenging. The research concerning patients undergoing stress before or during surgery revealed higher levels of anxiety and depression in those cases (1, 3). Nevertheless, the dysfunctional emotional reactivity of cardiac patients is one of the risk factors that explain the high level of postoperative mortality and morbidity (1), the longer postoperative hospital stay and physical recovery time, and the persistence of certain negative emotional states (3).

This research is focused on the variables associated with postoperative stress experienced by cardiac patients who underwent specific surgery. Thus, optimism is important for the postoperative course of cardiac patients. For the scholars this notion embodies the positive expectations (full of hope) a person experiences in a given situation (4). Optimistic stance tends to be a protective factor against functional deterioration and also a consistent indicator of the quality of life in patients with chronic afflictions (5, 6, 7, 8).

Another area of research that has generated numerous empirical clinical and health psychology studies is the relation between personality traits, stress, and health. Neuroticism/emotional instability is one of the most studied personality traits in relation with stress and/or other psychopathological manifestations, and also with adaptation to disease. This type of personality trait describes the general tendency of a person to experience negative emotions (anxiety, sadness, guilt, anger), irrational ideas, and difficulties in impulse control (9). The neurotic state tends to be one of the most important personality factors that determine the vulnerability of a person in stressful situations that influence the functions and adaptation strategies of a person (10).

On the other hand, given the complexity, extent, and risk (predictable and unpredictable complications) of heart surgery, it is natural that most cardiac patients to experience preoperative fear (cognitive preoccupations and unpleasant emotional reactions, accompanied by somatic-neural-vegetative reactions). There is a positive association between the level of preoperative fear and the risk of postoperative stress.

This article summarizes the results of a transversal study designed to explore the role of stress vulnerability (as expression of emotional instability), dispositional optimism, surgery-related fear, and negative affective stance in explaining the individual differences in the level of postoperative experienced by heart surgery patients. The practical applicability of this study consists in the identification of the predisposing individual traits (emotional and cognitive) which can explain the differences in postoperative medical and psychological outcomes between cardiac patients. These findings can be useful in preventive psychological counseling of patients about to undergo surgery and possibly experience a critical stress level.

MATERIAL AND METHODS

Sixty cardiac patients, admitted and operated (October, 2010 - May, 2011) in the "Prof. Dr. I. M. Georgescu" Institute of Cardiovascular Diseases at Iasi were assessed before and after surgery. The 39 male and 21 female patients were aged between 24 and 76 years (M = 58.50 years; SD = 10. 97 years). Over 75% of the patients had at least one cardiovascular disor-

der (high blood pressure, acute myocardial infarction, ischemic cardiomyopathy, coronary insufficiency, stroke), or other type of disorders (diabetes, prostate adenoma, chronic renal failure, plasmacytoma, gastric ulcer), treated over the past 5 years or on therapy. Almost half of the cardiac patients eligible and enrolled in this study underwent coronary bypass. Some of them also underwent other surgical procedure, such as: aortic prosthetic reconstruction, aneurysmectomy, mitral or tricuspid prosthetic reconstruction. The remaining patients underwent: aortic prosthetic reconstruction, mitral or mixed, subvalvular diaphragm resection, atrial myxomectomy, or surgical removal of an atrial septal defect. Surgeries were performed 1 to 28 days after admission (M = 7.40; SD = 5.37). On average, the patients required 15.45 days of postoperative hospital stay (SD = 0.01).

The patients completed two sets of standard questionnaires. The first set included five preoperative questionnaires (on average 5.11 days after admission; SD = 5.77), while the second set consisted in two questionnaires applied to the patients eight days after the surgery (SD = 3.15). Four of the questionnaires (scale N6 – stress vulnerability from NEO Personality Inventory – Revised Form/NEO PI-R, Life Orientation Test-Revised Form/LOT-R, Mental Health Index-5 Items Version/MHI-5, and Perceived Stress Scale/PSS) were taken from the literature, translated, and adapted to the purpose of this study. Three other questionnaires (socio-demographic data and medical history, scale for assessing surgery-related fear, and postoperative medical data) have been developed for this study. Stress vulnerability was measured according to the homonymous scale of NEO PI-R inventory (9). The instrument included eight items. The total score was obtained by summing the score of each item (range 0-32). A high score (range 0-24) was interpreted as high stress vulnerability. For our series of cardiac patients, the value of internal consistency was acceptable ($\alpha = 0.69$). The level of dispositional optimism was assessed with LOT-R (11, 12). The instrument has 10 items, of which 4 are distractors. A high score (range 0-24) signifies a high level of predisposition to conceptualized optimism. For our series patients, $\alpha = 0.65$. Surgery-related fear was assessed using an 8-item scale. The total score was obtained by summing the item scores (range 0-32). A high score was interpreted as a high level of concern regarding heart surgery. For our series of patients the value of internal consistency was acceptable ($\alpha = 0.67$). The negative affective disposition experienced by our patients in the last month was assessed with MHI-5 (13). The instrument is part of the Medical Outcomes Study 36-item Short Form Health Survey and it includes 5 items. A high score (range 0-25) indicates a high level of the negative affective disposition. For our series of patients the value of internal consistency was 0.73.

Postoperatively, the patients completed a short modified version (10 items) of PSS (14). In the original version, the instrument has been developed to evaluate the degree to which individuals believe their life has been unpredictable, uncontrollable, and overloaded during the previous month (15). The assessed items are general in nature rather than focusing on specific events or experiences. In this study a high score (range 0-40) was interpreted as an indicator of a high postoperative stress. The value of the internal consistency was good ($\alpha = 0.82$). More than 25% of the cardiac patients developed clinical complications due to unfavorable postoperative course. Two

patients (1 man and 1 woman) died. Only one of them survived long enough to participate in postoperative assessment. Another patient (who survived) refused it. Thus, PSS scores were obtained from 58 of the 60 patients.

RESULTS

Over 50% of the investigated patients had a moderate postoperative stress score (15-24), 4 patients a moderate to high (score 25-27), and other 5 – a high or very high score (28-36).

There was a positive correlation between the level of postoperative stress and the levels of the stress vulnerability (as personal predisposition), surgery-related fear, and preoperative negative affective disposition, and a negative correlation with the dispositional optimism score (tab.I). In the patients who developed complications due to unfavorable postoperative course, the correlation between postoperative stress level and stress vulnerability ($N = 17$; $r = 0.75$; $p = 0.001$; two-tailed) was stronger than in the patients who did not experience postoperative complications ($N = 41$; $r = 0.53$; $p < 0.001$; two-tailed), but the difference was not significant ($z_{r1-r2} = 1.22$; $p = 0.22$; two-tailed).

TABLE I

Correlations between the measured variables

Variables	M ± SD	Correlations with the level of postoperative stress
1. Postoperative stress	17.50 ± 6.11	-
2. Stress vulnerability	10.90 ± 3.93	0.57 ***
3. Dispositional optimism	13.70 ± 2.96	- 0.38 **
4. Surgery-related fear	13.10 ± 3.29	0.47 ***
5. Negative affective disposition (preoperative)	10.35 ± 4.33	0.45 ***
6. Age	58.50 ± 10.97	- 0.13
7. Preoperative hospital stay (number of days)	7.40 ± 5.37	- 0.06
8. Postoperative hospital stay (number of days)	15.45 ± 10.87	- 0.04

** $p < 0.01$; *** $p < 0.001$

The correlations between postoperative stress level and patients' age, duration of pre- and postoperative hospital stay were not statistically significant.

The difference in PSS scores between female and male patients were not statistically significant (women/18.52 ± 5.53; men/18.52 ± 5.53; $t = 0.96$; $p = 0.34$; two-tailed). Also, the complications due to unfavorable postoperative course had an insignificant influence on postoperative stress (patients with complications/19.11 ± **7**.13; patients without complications /16.82 ± 5.59; $t = 1.30$; $p = 0.19$; two-tailed). However, the patients who developed postoperative complications presented a slightly higher level of stress. The difference between the average score of patients on treatment for diagnosed conditions ($N = 46$; 17.52 ± 6.34), and patients not on treatment ($N = 11$; 17.72 ± 5.53) was not high enough to be significant ($t = - 0.09$; $p = 0.92$; two-tailed).

Stress vulnerability, dispositional optimism, surgery-related fear, and negative affective disposition were all taken into account as independent variables of linear regression model, where the dependent

variable (the criterion) was the level of postoperative stress. The coefficient of multiple correlation was statistically significant ($R = 0.66$; $F = 10.47$; $p < 0.001$; two-tailed). Together with the constant, the independent variables accounted for about 40% of the variation in postoperative stress score distribution, but only stress vulnerability and negative affective disposition were significant predictors (Table II). The score of stress vulnerability accounted for 13.1% of postoperative stress variation, while the negative affective disposition score 5.1%.

TABLE II

Multiple linear regression data

Independent variables	B	SE	β	r^2_{sp}
Stress vulnerability	0.67	0.19	0.42 **	0.131
Dispositional optimism	- 0.12	0.25	- 0.06	0.002
Surgery-related fear	0.21	0.26	0.11	0.007
Negative affective disposition	0.38	0.17	0.26 *	0.051

$p < 0.05$; ** $p < 0.01$ (two-tailed)

DISCUSSION

Scientists unanimously agree that surgery is a stressful factor for those directly involved (the patients), as well as for their family and friends (1, 3, 16, 17). Our correlational data of dispositional optimism and concerns about surgical outcome are all in agreement with those reported by other studies on the mental health and perception of the quality of life among cardiac patients undergoing heart surgery life (5, 7).

In this study the scores of stress vulnerability and negative affective disposition were positive predictors of the level of postoperative stress experienced by cardiac patients. As an aspect of neurosis, stress vulnerability is characteristic to people feeling unable to cope with difficulties, and who are prone to experience helplessness and being emotionally dependent of others (9). Such people are liable to exhibit dysfunctional ways of coping, and difficult recoveries after stressful experiences. On the other hand, the negative affective disposition (i. e. depressive symptoms) is rather common among patients awaiting heart surgery (17, 18, 19).

In a future study we want to continue the analysis of the factors that could explain the patient differences with respect to the psychological and medical indicators of recovery after heart surgery. This would be possible by including other variables, such as: predisposition for anxiety, postsurgical expectancies, perceived self-efficiency, coping abilities (and style) for stressful situations, trust in future and emotional and social support from family.

CONCLUSIONS

Even though the literature emphasizes the importance of preparing a patient for surgery to help them deal with problems resulting from hospital stay, surgery itself, convalescence, rehabilitation period, and increase their resilience to stress (20), many of the medical professionals do not regard this action as an essential part of a comprehensive and integrative medical act (16). In these circumstances it is not surprising that poor psychological status experienced pre-surgically by patients is significantly associated with difficulties of postoperative recovery, this fact emphasizing the importance of psychological factors in the dynamics of medical treatment.

Knowledge by the medical staff of the individual traits of cardiac patients and implementation of specialized pre-and postoperative counseling can help increase resilience to stress and thereby improve the indicators of medical rehabilitation.

DEVELOPMENT AND OPTIMIZATION OF THE SYNTHESIS OF NEW THIAZOLIDIN-4-ONE DERIVATIVES OF IBUPROFEN (Abstract): Ibuprofen, an important nonsteroidal anti-inflammatory agent, is one of the most prescribed drugs for the treatment of pain and inflammation from various rheumatic diseases, but some side effects can occur on long-term use. **Aim:** The method for synthesis optimization of new derivatives of Ibuprofen with thiazolidin-4-one moiety, with improved pharmacological and toxicological profile. **Material and methods:** To optimize the derivatization method of free carboxyl group of Ibuprofen (2-(4-isobutylphenyl)propionic acid) the reaction conditions were varied (reagent ratio, catalyst, reaction medium). **Results:** The most favorable method was proved to be the reaction between ibuprofen hydrazone and mercaptoacetic acid, in excess, at 80-85°C, for 6 h with 96% conversion rate. **Conclusions:** The synthesis of 2-phenyl-3-[2-(4-(isobutyl)phenyl)-2-methyl]acetamido-thiazolidin-4-one derivative was optimized in view of applying it as a general procedure for the synthesis of other derivatives with related structure. The chemical structure and molecular weight of the synthesized compound were confirmed by spectral methods (IR, ^{1}H NMR, ^{13}C NMR, HR-MS). **Keywords:** IBUPROFEN, THIAZOLIDIN-4-ONE, SYNTHESIS, OPTIMIZATION.

Development of new nonsteroidal anti-inflammatory drugs (NSAIDs) is the major concern of researchers in the field because of the impact of inflammatory and rheumatic diseases on patient health status. NSAIDs are some of the oldest classes of drugs, the humanity having being related to pain, fever and inflammation from its beginnings. From *Hippocrates* who used a willow bark extract to treat fever and inflammation to the discovery of salicin and then the synthesis of salicylic acid, the researches have evolved and at the end of 19th century, *Hoffman* synthesized the acetylsalicylic acid, which was introduced in therapy under the name Aspirin by Bayer Company (1).

Researches on the discovery of new active drugs, safer than classical therapeutic agents had continued and so Ibuprofen was patented as a new analgesic and anti-inflammatory drug in 1961 by *Dr. Stewart Adams* (Boots Company) and his collaborators. Even if Ibuprofen was proved to be an efficient therapeutic alternative to treat

inflammatory and rheumatic diseases, its long-term use was associated with gastrointestinal and renal side effects. Today, it is known that the toxicological potential of Ibuprofen is related to the lack of the cyclooxygenase (COX) selectivity, an enzyme responsible for prostaglandin synthesis. Ibuprofen is a nonselective COX inhibitor that inhibits COX-2 isoform at the site of inflammation but also COX-1 isoform responsible for the gastric cytoprotective prostaglandin synthesis (2).

To increase the analgesic and anti-inflammatory activity and reduce the side effects, the recent researches were focused on derivatization of carboxyl group of classical NSAIDs with various heterocyclic systems (oxazole, izoxazole, pyrazole, oxadiazole, thiazole, thiadiazole, triazole etc.) (2, 3).

On the other hand, thiazolidin-4-one derivatives are an important class of heterocyclic organic compounds because of their various biological properties: anti-inflammatory and analgesic activity (4), antimicrobial, antifungal (5) and antimycobacterial effects, antioxidant potential (6), antiviral and anti-HIV activity, anticonvulsant effect (7), hypoglycemic or antitumor activity (6).

In order to develop potential new therapeutic agents with anti-inflammatory properties, a general procedure for the synthesis of thiazolidin-4-one derivatives by structural modulation of carboxyl free group of ibuprofen has been optimized.

MATERIAL AND METHODS

Ibuprofen sodium salt, thionyl chloride, hydrazine hydrate, benzaldehyde, mercaptoacetic acid, organic solvents (*p.a.* quality) were purchased from Sigma Aldrich Company.

Fourier transform infrared (FTIR) spectra were recorded on a FT-IR Bomem MB-104 spectrometer (Canada), with a resolution of 4 cm^{-1} after 32 scans between 4000 and 600 cm^{-1}. NMR spectra (^{1}H-NMR, ^{13}C-NMR) were determined using NMR Bruker 400 MHz spectrometer (Germany), and molecular weight was determined by using Maxis Bruker high resolution mass spectrometer.

Chemistry

The synthesis of thiazolidin-4-one derivative of Ibuprofen (9) was realized through two methods (fig. 1).

Method A is based on "one step" reaction between Ibuprofen hydrazide (**5**), benzaldehyde (**6**) and mercaptoacetic acid (**7**) using different ratios between reagents, reaction medium, catalyst, time and reaction temperature.

Method B is a two-step reaction that firstly involves the condensation of hydrazide (**5**) and benzaldehyde (**6**) resulting Ibuprofen hydrazone (**8**), which in the next step is cyclized with mercaptoacetic acid (**7**) using various ratios between reagents, reaction medium, catalyst, time and reaction temperature.

Ibuprofen hydrazide was obtained from ibuprofen (2-(4-(isobutyl)phenyl)propionic acid) (**2**) that was formed by treating the sodium salt (**1**) with hydrochloric acid. After several steps that include the synthesis of acid chloride (**3**), its conversion to corresponding ethyl ester (**4**) and then the reaction with excess hydrazine hydrate, the Ibuprofen hydrazide (**5**) was obtained (8).

General procedure for synthesis of thiazolidin-4-one derivatives of Ibuprofen

Method A. In a corresponding flask were introduced 2-(4-isobutylphenyl) pro-

pionyl hydrazine (MW = 220,31 g/mol), benzaldehyde (MW = 106,12 g/mol, d = 1,0415 g/cm^3) and mercaptoacetic acid (MW = 92,12 g/mol, d = 1,32 g/cm^3). The reaction conditions were modified: reagents ratio (1.5:1:1.3; 1:2:3), reaction medium (anhydrous toluene, dichloromethane = DCM), reaction temperature (120°C, 22°C), time (24h, 45h), in the presence or absence of catalyst (N,N`-dicyclohexyl-carbodiimide, DCC). The reaction mixture was evaporated and the obtained residue was dissolved in ethyl acetate. The organic layer was washed with sodium bicarbonate, sodium chloride (saturated solutions) and water, after which it was dried under anhydrous $MgSO_4$, filtered and concentrated under reduced pressure.

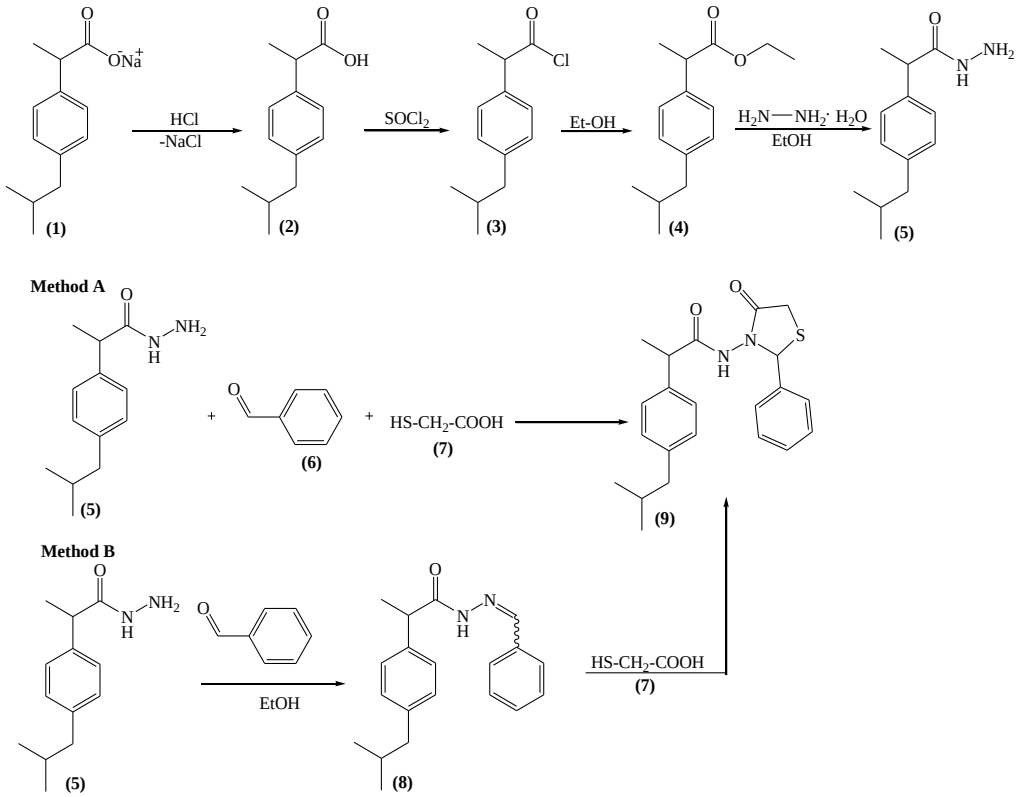

Fig.1. Scheme of the synthesis of Ibuprofen derivative with thiazolidin-4-one structure

Method B. N′-benzylidene-2-(4-isobutylphenyl)propionyl hydrazine (MW = 308.42 g/mol) and mercaptoacetic acid (MW = 92,12 g/mol, d = 1,32 g/cm^3) were introduced in a flask. The reaction conditions were modified: reagents ratio (1:1.5; 1:1.3; 1:1.5; 1:4.5), reaction medium (anhydrous toluene, anhydrous dioxane, acetic acid), reaction temperature (80-85°C, 105°C, 120°C), time (6h, 12h, 24h, 30h, 38h), catalyst (zinc chloride, sodium acetate). The reaction mixture was dissolved in

ethyl acetate and the organic layer was extracted and washed with sodium bicarbonate, sodium chloride (saturated solutions) and water. The organic layer was collected, dried under anhydrous $MgSO_4$ and filtered. After evaporation under reduced pressure, the residue was purified by flash chromatography on silica gel column (dichloromethane:methanol = 9.8:0.2) resulting a colorless residue that was precipitated with diethyl ether to afford a white powder (reaction condition - reagents ratio 1:4.5, reaction temperature 80-85°C, time reaction 6h).

RESULTS AND DISCUSSION

The analysis of nuclear magnetic resonance spectra revealed that the application of method A for synthesis of 2-phenyl-3-[2-(4-(isobutyl)phenyl)-2-methyl]acetamido-thiazoli-din-4-one derivative was carried on conversion rate between 40% and 60%. The highest rate (60%) was obtained when anhydrous toluene was used as reaction medium at 120°C and during 24 hours (tab. I).

For method B it was observed that the reagent conversion rates in the final compound was between 34% and 96%, which varied according to the reaction conditions (reagents ratio, reaction medium, temperature, time, catalyst). The highest conversion rate was 96% when the mercaptoacetic acid was used in excess (1:4.5). At temperatures higher than 95°C (120°C) the synthesis of the final compound but also the presence of the mercaptoacetic dimmer that could not be removed by crystallization, precipitation, liquid-liquid extraction, flash chromatography on silica gel column were observed (tab. I).

The chemical structure of the thiazolidin-4-one derivative was confirmed by IR, NMR and HR-MS spectroscopy. In IR spectrum the characteristic absorption bands of the functional groups were identified. The characteristic absorption band of amidic group (CO-NH-) was observed at 1666 cm^{-1} and the cyclic C=O group (thia-

zolidin-4-one) appeared at 1716 cm^{-1}. The characteristic band of C-S bond was identified at 694 cm^{-1} and the NH group at 3243 cm^{-1}. The aromatic ring was observed by the characteristic absorption bands of C-H bond at 2959 cm^{-1}.

TABLE I
Optimization of synthesis of thiazolidin-4-one derivative

Method		Reagents (eq.)		Catalyst (eq.)	Solvent	t°C	Time (h)	C (%)

C (%) = conversion percentage in the final compound

The aromatic ring protons were identified on ^{1}H-NMR spectrum as multiplet and doublet signals at 7.50-7.01 ppm, and the NH proton appeared at 10.26 ppm. The proton of CH from thiazolidin-4-one appeared as singlet at 5.82 ppm and the characteristic protons of the two aliphatic CH groups were identified as multiplet or doublet signals at 3.61-3.47 ppm or 1.79 ppm. The characteristic protons of CH_2 from thiazolidin-4-one were observed as triplet or doublet signals at 3.86 ppm and 3.72 ppm. The protons of aliphatic CH_2 were identified in ^{1}H-NMR spectrum as doublet signal at 2.39 ppm and the protons of the three CH_3 appeared as doublet of doublet or doublet at 1.25 ppm or 0.85 ppm.

In the ^{13}C-NMR spectrum the aromatic carbons were identified at 128.69-126.87 ppm, the carbon of the thiazolidin-4-one cyclic CH appeared at 61.43 ppm and for the aliphatic CH at 42.12 or 29.62 ppm. The CH_2 carbons were observed at 29.27 ppm for the thiazolidin-4-one cycle and at 44.22 ppm for the aliphatic moiety. The two methyl group (-CH_2-CH-***(CH$_3$)$_2$***) resonances were superimposed in one peak at 22.13 ppm and the third one (-CH-***CH$_3$***)

appeared as two peaks at different values 18.81 ppm and17.90 ppm because the E/Z isomerism.

High Resolution Mass Spectroscopy confirmed the molecular weight of the synthesized compound.

CONCLUSIONS

Two synthesis methods of new thiazolidin-4-one derivative of Ibuprofen were developed in order to be used as general procedure for synthesis of new ibuprofen derivatives. The most efficient conversion rate was obtained when the Ibuprofen hydrazone was reacted with mercaptoacetic acid, at 80-85°C for 6 h. The structure of the synthesized derivative of Ibuprofen was confirmed by Infrared spectroscopy (IR), Nuclear Magnetic Resonance spectroscopy (^{1}H-NMR, ^{13}C-NMR) and High Resolution Mass Spectroscopy (HR-MS).

THE CHEMICAL COMPOSITION OF ESSENTIAL OILS ISOLATED FROM SWEET FENNEL FRUITS AVAILABLE AS HERBAL TEA PRODUCTS (Abstract): Sweet fennel fruits (*Foeniculum vulgare* subsp. *vulgare* var. dulce Mill.) are a spice with various uses in medicine, but also in food, pharmaceutic and cosmetic industries. Their biological activities as well as the flavoring properties are due to the essential oil. **Aim**: In this paper, the essential oils obtained from seven Romanian fennel herbal tea products were comparatively characterized in terms of their chemical composition. **Material and methods:** The volatile oils obtained by hydrodistillation, according to the Ph. Eur. 6th edition, were analyzed by GC and GC-MS. **Results**: The volatile oil content of fennel herbal tea products varies widely (28.10-101.00 mL/kg dried fruits), but all the samples meet the requirements of the Ph Eur. 6th edition (min. 20 mL/kg dried fruits). Phenylpropanoid derivatives (52.12%-57.66%) and monoterpenes (39.25%-45.28%) represent the bulk of the fennel volatile oils. Trans-anethole, estragole, limonene, fenchone, α-pinene, γ-terpinene and myrcene were the main compounds in all samples, but their levels vary greatly. **Conclusions**: The Romanian fennel herbal tea products showed important differences in terms of volatile oil content. The qualitative and quantitative differences in the chemical composition of fennel volatile oils were also observed. The most striking variations concern trans-anethole and estragole phenylpropanoid derivatives. Furthermore, these variations could have a significant impact on the flavouring and biological effects of fennel volatile oils. **Keywords:** *FOENICULUM VULGARE*, ESSENTIAL OILS, CHEMICAL COMPOSITION.

Sweet fennel (*Foeniculum vulgare* subsp. *vulgare* var. dulce Mill, Apiaceae), is a valuable medicinal and aromatic plant, native in the Mediterranean area. Fennel fruits and their volatile oil are largely used as a flavouring agent in food, pharmaceutical and cosmetic products. In traditional Romanian medicine, fennel fruits are recommended in the treatment of dyspeptic disorders and symptoms of the upper respiratory tract, but also to prevent flatulence and spasms in nursing infants. The pharmacological effects of fennel are largely atributed to their essential oil. Various experimental studies have reported multiple biological activities for fennel essential oil: hepatoprotective, antioxidant, antithrombotic, antiinflammatory, antidiabetic or antimicrobial (1, 2, 3, 4, 5). The chemical composition of volatile oils is decisive for

the expression of their biological activity, but, in turn, it is influenced by many endogenous and exogenous factors, such as: fruit ripening stage, agronomic practices, pedoclimatic conditions, geographic area or extraction method (6).

Considering those facts, in this paper, the essential oils obtained from seven Romanian fennel herbal tea products were comparatively characterized in terms of their chemical composition.

MATERIAL AND METHODS

Plant samples. Seven herbal tea products of fennel fruits were purchased from local pharmacies in May 2011. All samples were available in 50g packets, came from various inland producers, and they had been manufactured in the same year (2010). The codification of the samples was made as follows: Fares Orastie-FT1; Plafar Bucuresti-FT3; Trident Ilfov-FT4; Dacia Plant batch 11677/1-FT4; Dacia Plant batch 11677/8-FT5; Larix Sovata-FT6; Cyani Ploiesti-FT7.

Essential oils isolation. The essentials oils were obtained from dried fruits by hydrodistillation in the Clevenger apparatus (2 hours), according to the European Pharmacopoeia 6th edition (7). The volatile oils were separated, dried over anhydrous sodium sulfate and kept in a dark glass bottle at 4°C for the analysis.

GC-MS analysis. The GC-MS analysis of the volatile oils was carried out on an Agilent type 7890A gas cromatograph, equipped with an Agilent 5975C mass spectrometer and a DB-5MS capillary column (25 m x 0.25 mm internal diameter, 0.25 µm film thickness). The injection volume was 0.3 µL of pure essential oil. The oil samples were injected in split mode (split ratio: 100/1), using pressured controlled He as carrier gas with a flow rate of 1 mL/min. The injector and detector temperatures were maintained at 250°C. The analyses were performed using the following temperature program: the oven temperature was raised at a rate of 3°C min^{-1} from 40 to 250°C (isothermal for 4 min), then raised to 280°C at 10°C min^{-1} and the final temperature was held for 8 min. The identification of the components was based on the comparison of their mass spectra in the apex of each peak with those of analytical standards from Willey Mass Spectral Library.

RESULTS

The volatile oil content of fennel samples varies widely (28.10-101.00 mL/kg dried fruits) (fig.1). The FT6 (Larix), FT7 (Cyani) and FT1 (Fares) were the richest samples (101 mL/kg; 92.7 mL/kg and 71.1 mL/kg). All volatile oils comply with the requirements of the European Pharmacopoeia 6th edition (min. 20 mL/kg dried fruits).

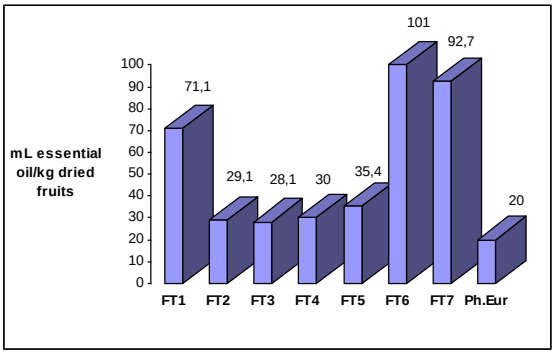

Fig.1. Essential oil content (mL/kg) of dried fennel fruits

The results of the GC-MS analysis are showed in table I.

*RT, retention time

In the fennel volatile oils were identified a variable number of components, as follows: twenty-six in FT1, forty in FT2, thirty-nine in FT3, forty-two in FT4 and FT5, twenty-eight in FT6 and thirty-five in FT7, representing 99.17%, 99.49%, 99.03%, 98.60%, 98.93%, 98.70% and 98.08%, respectively, of the total oil (tab. I).The major constituents in all samples were: trans-anethole, estragole, fenchone, limonene, α-pinene, γ-terpinene and myrcene. Phenylpropanoid derivatives were the predominant compounds representing between 52.12% and 57.66% of the fennel volatile oils' composition (tab. I, fig. 2). FT2 (Plafar Bucuresti) and FT5 (Dacia Plant lot 2) were the richest samples in such components (57.66% and 57.27%, respectively). The monoterpenes (hydrocarbons and oxygenated derivatives) constitute the second most important structural group of the fennel volatile oils, with values between 39.25% and 45.28%. The highest levels of monoterpenes were found for samples FT6 (Larix) and FT7 (Cyani) (44.81% and 45.28%, respectively). Sesquiterpenes were absent (FT6) or poorly represented (below 2%).

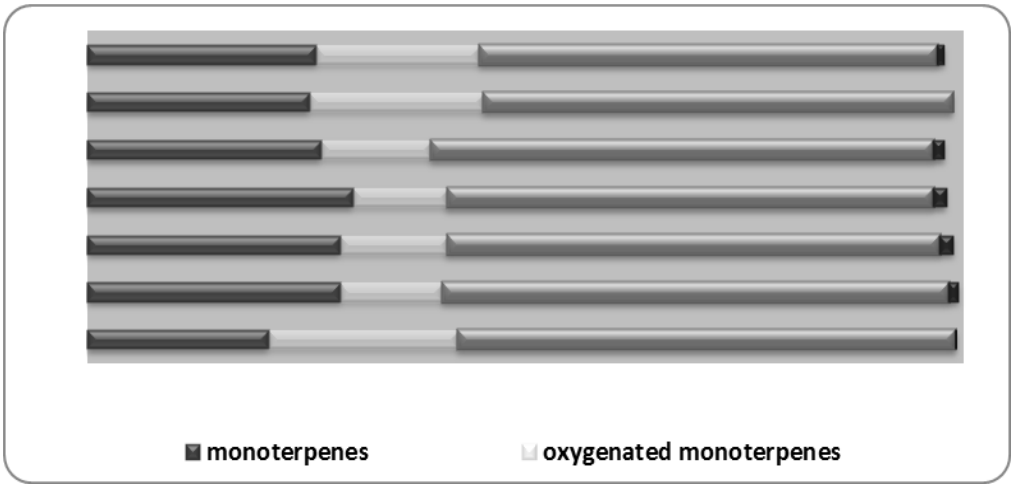

Fig. 2. The percent composition of fennel volatile oils on major component types

DISCUSSION

The content of volatile oil in fennel samples is good, but it varies largely. Thus, in FT6 (Larix), the volatile oil content was about 3.6 times higher than in FT3 (Trident). The variations concern not only the samples from diverse producers, but they were registered at different batches of the same producer (FT4 and FT5 samples), even if they are of lower magnitude (only 1.18 times). Regarding their chemical composition, fennel volatile oils are predominantly composed of phenylpropanoid derivatives (over 50%) and monoterpenes. The number and proportion of the components from each structural group also varies. The main phenylpropanoid compounds encountered in fennel volatile oils, like trans-anethole and estragole, were present in all samples, but there are significant differences regarding their proportion (even about 6 times). Trans-anethole was the major compound only in FT1 (Fares), FT6 (Larix) and FT7 (Cyani) fennel herbal tea products, while in FT2 (Plafar Bucuresti), FT3 (Trident), FT4 and FT5 (Dacia Plant), estragole predominated. It is interesting that the lowest level of oxygenated monoterpenes (10.86%-12.62%) was found in the same samples (FT2-FT5). These differences are even more important as estragole is suspected to be carcinogenic, and its intake should be restricted (8).

CONCLUSIONS

The fennel herbal products were characterized by a highly variable content of volatile oils. The richest samples were Larix-Sovata, Cyani-Ploiesti and Fares-Orastie, with 101 mL/kg, 92.7 mL/kg and 71.1 mL/kg respectively. Trans-anethole, estragole, fenchone, limonene, α-pinene, γ-terpinene and myrcene were the main components in all volatile oils, but they were present in varying proportions. The most striking differences concern the level of trans-anethole and estragole phenylpropanoid derivatives. Trans-anethole was the major compound in Fares (Orastie), Cyani (Ploiesti) and Larix (Sovata) while estragole prevailed in the other samples. Furthermore, these variations could have a significant impact on the flavoring and biological effects of fennel volatile oils.

NEWS

CLOSTRIDIUM DIFFICILE INFECTION IN LUNG CANCER PATIENTS

Clostridium difficile infection (CDI) is a common nosocomial infection. Lung cancer patients have a high risk of developing CDI because of continuous antibiotic treatment or chemotherapy, prolonged hospitalization, and general weakness. This study aimed to analyze predisposing or associated risk factors for CDI in lung cancer patients receiving chemotherapy. This study was a retrospective review of 188 lung cancer patients who were admitted to the Wonkwang University Hospital between 2008 and 2009. Of the 188 patients, 44 were diagnosed with CDI. The albumin levels were significantly lower and the performance status (PS) score was significantly higher in lung cancer patients with CDI than in those without CDI ($P < 0.05$). In conclusion, clinicians should consider the possibility of CDI occurrence in lung cancer patients receiving chemotherapy, particularly in those with low albumin levels and high PS scores, because most lung cancer patients have a high risk of developing CDI. (Hwang KE, Hwang YR, Seol CH, et al. *Clostridium difficile* infection in lung cancer patients. *Jpn J Infect Dis* 2013; 66(5): 379-82)

NEW DERIVATIVES OF ARYL-PROPIONIC ACID. SYNTHESIS AND BIOLOGICAL EVALUATION(Abstract): **Aim:** To design new derivatives of aryl-propionic acid with potential antibacterial and antioxidant activity. **Material and methods**: New hydrazone of ibuprofen (2-(4-isobutylphenyl)propionic acid) have been synthesized by reaction of ethyl ester of ibuprofen with hydrazine hydrate and then condensation of corresponding hydrazide with various aromatic aldehydes. **Results:** The synthesized compounds were screened for their antibacterial activity against Gram positive (*Staphylococcus aureus*ATCC 25923, *Sarcinalutea*ATCC 9341, *Bacillus cereus*ATCC 14579, *Bacillus subtilis*) and Gram negative bacterial strains (*Escherichia coli*ATCC 25922). Some of them were found to have good antibacterial activity. The antioxidant activity of these compounds was also tested using the total antioxidant capacity test. **Conclusions:** The chemical modulations performed on ibuprofen structure have a good influence on the biological activity of the synthesized compounds. **Keywords:** IBUPROFEN, HYDRAZIDE, HYDRAZONE, ANTIBACTERIAL, ANTIOXIDANT.

The aryl-propionic acid derivatives are a large and important family of nonsteroidal anti-inflammatory agents (NSAIDs) (1). Ibuprofen, chemically called 2-(4-isobutylphenyl) propionic acid, is a well-known drug which has analgesic (pain-relieving), antipyretic (fever-reducing) and anti-inflammatory properties (2, 3). It is particularly known for its use in pain relief from arthritis (4). Long-term use of NSAIDs has been associated with gastro-intestinal (GI) ulceration, bleeding and nephrotoxicity (5). The gastrointestinal (GI) damage is generally attributed to two factors: local irritation by carboxylic acid moiety, common to most NSAIDs (topical effect) and decreased tissue prostaglandin production, which reduces the physiological role of cytoprotective prostaglandins in maintaining GI health and homeostasis (6). Studies described that the derivatization of the carboxylate function of representative NSAIDs resulted in an increased anti-inflammatory activity with reduced ulcerogenic effect. Furthermore, certain compounds bearing 1,3,4-oxadizole/thiadiazole and 1,2,4-triazole nucleus have been reported to possess significant anti-inflammatory

activity (7-8). In the last two decades there has been a considerable amount of interest in the role of reactive oxygen species in inflammation. Inflammation is one of the manifestations of oxidative stress, and the pathways that generate the mediators of inflammation, such as adhesion molecules and interleukins, are all induced by oxidative stress (9).

In our attempt to discover new and useful agents for treating inflammatory diseases we have replaced the carboxylic acid group with hydrazone group. The synthesized compounds were physicochemically and spectrally characterized and their antioxidant and antimicrobial potential assessed.

MATERIAL AND METHODS

Ibuprofen, hydrazine hydrate, aromatic aldehydes (benzaldehyde, 2-NO_2/3-NO_2/4-NO_2-benzaldehyde, 4-Cl/4-F/4-Br-benzaldehyde, 2-OH/4-OH-benzaldehyde, 2-OCH_3-benzal-dehyde, 4-dimethlaminobenzaldehyde, organic solvents (*p.a.* quality), standard reagents for antioxidant and antimicrobial tests, were purchased from Sigma Aldrich Company. All solvents and reagents were used without further purification.

Chemistry.*Synthesis of ibuprofen derivatives.*Ibuprofen (2-(4-isobutyl-phenyl) propionic acid) (1) was reacted with ethanol in acidic conditions and the resulting ethyl ester (2) was treated with hydrazine hydrate. The corresponding hydrazide (3) was condensed with various aromatic aldehydes, resultingnew hydrazone derivatives (4-14) of ibuprofen (fig. 1).

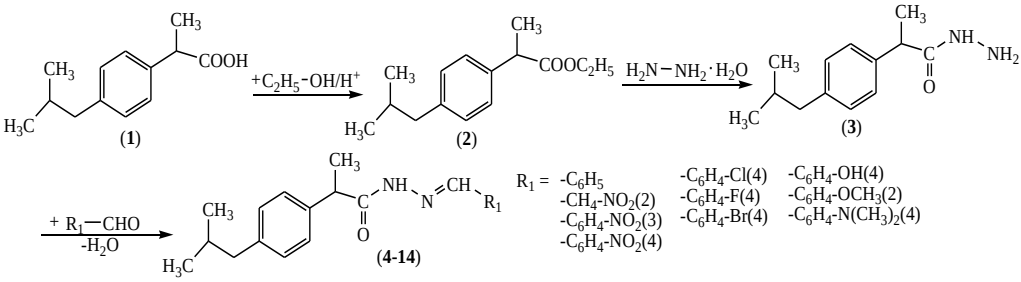

Fig. 1. Synthesis of new hydrazones of ibuprofen

Synthesis of ethyl ester of ibuprofen (2). Ibuprofen (0.08 mol, 16.5 g) was treated with ethanol (70 ml) in the presence of sulphuric acid (2 ml) as catalyst. The mixture was heated under reflux for 8 h, and then the solution was neutralized with sodium carbonate 100 g/L until pH 8. The product was extracted 3 times with ethyl ether, dried with sodium sulphate, filtered and evaporated under reduced pressure. The product was a yellow liquid, b.p. 260-262°C. IR (cm^{-1}): 1750 (CO), 3350 (C-OH).

Synthesis of ibuprofen hydrazide(3).The ethyl ester of ibuprofen (0.07 mol) a solution of hydrazine hydrate 98% (0.3 mol) and ethanol (60 ml) were added. The mixture was heated under reflux for 12 h, and then concentrated to ¼ of initial volume. The product was treated with cold water when the hydrazide of ibuprofen was separated under stirring as white solid, m.p. 70-73°C. IR (cm^{-1}): 1645 (CO-NH), 3420, 3280 (NH_2).

General procedure for synthesis of 1-(R-benzyliden-hydrazinyl)-2-(isobutylphenyl)-

propionamide(4-14).To a solution of ibuprofen hydrazide (0.012 mol, 2.83 g) (3) in ethanol (50 ml), aromatic aldehydes (0.012 mol) and glacial acetic acid (2-3 drops, pH 4-5) were added. The reaction mixture was heated under reflux for 5 h. After cooling the obtained solid was filtered off and recrystallized from ethanol.

Characterization by FTIR Spectroscopy. Fourier transform infrared (FTIR) spectra were recorded on a FT-IR Bomem MB-104 spectrometer (Canada). FTIR spectra were acquired after 32 scans between 4000 and 600 cm^{-1}, with spectral resolution of 4 cm^{-1}. Spectra processing was carried out with a Grams/32 program (Galactic Industry Corporation).

Antioxidant assays. *Determination of total antioxidant capacity*.The antioxidant activity of tested compounds was evaluated by the phosphomolybdenum method according to the procedure of (10) with minor modifications. Briefly, 300 µL sample solution (500 µg/ml) in DMSO was mixed with the reagent solution (2 ml, 0.6 M sulphuric acid, 28 mM sodium phosphate, and 4 mM ammonium molybdate). The samples were incubated at 95°C for 90 minutes. After the mixture had cooled to room temperature, the absorbance of each solution was measured at 695 nm against a blank (DMSO mixed with reagent solution). Ascorbic acid (AA) was used as standard antioxidant in the same concentration of the samples.

Antimicrobial assessment. The antimicrobial activity was evaluated using Gram positive (*Staphylococcus aureus*ATCC 25923, *Sarcinalutea*ATCC 9341, *Bacillus cereus*ATCC 14579, *Bacillus subtilis*,), and Gram negative (*Escherichia coli*ATCC 25922) bacterial strains. An extended-spectrum beta-lactamase-producing strain, *Escherichia coli*CTX-M-14, was also used. Antimicrobial activity was evaluated by agar disc diffusion method according to described protocols (CLSI, 2012). Sterile stainless steel cylinders (50 mm internal diameter, 100 mm height) were applied on the agar surface in Petri plates. 200 µL of the tested compounds (4-14) (10 mg/ml) were added to each cylinder. Commercially available discs containing ampicillin (25 mg/disc), chloramphenicol (30 mg/disc) were used. The plates were incubated at 37°C for 24 h. After incubation the diameters (mm) of inhibition zones were measured.

RESULTS AND DISCUSSION

Chemistry. The physical measurements of the compounds are presented in tab. I and the characteristic IR spectroscopic bands are given in tab. II.

In the IR spectra of the hydrazone derivatives of ibuprofen (compounds 4-14) the characteristic absorption bands of all functional groups were observed. The absorption band for the C=O group was in the range of 1656-1673 cm^{-1} and for the C=N group in the range of 1528-1548 cm^{-1}. The characteristic band for the NH group appears in the range of 3144-3275 cm^{-1}, and due to the phenyl ring (C-H arom) the absorption band was observed at 2947-2965 cm^{-1}. The bands of the benzilydene ring substituents appeared in the range of 1520-1537 cm^{-1} (NO_2 group), 778 cm^{-1} (C-Cl), 1142 cm^{-1} (C-F), 706 cm^{-1} (C-Br), 3043-3053 cm^{-1} (Ar-OH), 3070 cm^{-1} (OCH_3) and 2838 cm^{-1} (CH_3). The presence of these bands confirmed the chemical structure of the synthesized compounds.

Antioxidant assays. *Determination of total antioxidant capacity*. The assay for total antioxidant capacity is based on the reduction of Mo^{+6} to Mo^{+5} by the tested com-

pounds followed by formation of a green phosphate/ Mo^{+5} complex at acidic pH. The results of the tested compounds are listed in tab. III. The test was carried out in triplicate. Data were statistically analyzed by the analysis of variance (ANOVA) ($p < 0.05$) and were expressed as means ± SD. The most active compound was derivative (12) obtained through condensation of hydrazide of ibuprofen with 4-hydroxibenzaldehyde. For this compound the absorbance was 0.3862± 0.0551, being four times more active than unsubstitutedbenzylidenhydrazone derivative (4) (0.1070±0.019). Compared to ascorbic acid (AA) all tested compounds were less active in similar conditions.

Antimicrobial assessment. The inhibition zone diameter (mm) of the tested compounds is listed in tab. IV. According to the obtained results some compounds were active on Gram positive bacterial strains, especially *Staphylococcus aureus* ATCC 25923. The most active compounds were 6, 7 and 12, their inhibition zone diameter being 20 mm (6, 7) and 21 mm (12). The compound with broad antibacterial spectrum was compound 9 which was active on *Staphylococcus aureus* ATCC 25923 (15 mm), *Sarcinalutea* ATCC 9341 (12 mm) and *Bacillus cereus* ATCC 14579 (14 mm).

CONCLUSIONS

Some new hydrazones of ibuprofen have been synthesized and optimal conditions of reaction were established for obtaining compounds with high yields and advanced purity. The synthesized compounds have been physically characterized (melting point, yield, molecular formula,

molecular weight, solubility in different organic solvents), and their chemical structure was confirmed by FT-IR spectroscopy. Their antibacterial and antioxidant activities have been also evaluated. Some compounds have antimicrobial and antioxidant activity.

THE POLYPHENOLIC CONTENT OF COMMON *LAMIACEAE* SPECIES AVAILABLE AS HERBAL TEA PRODUCTS IN ROMANIAN PHARMACIES (Abstract): The plants belonging to *Lamiaceae* family are widely used in medicine, cosmetic and food industry. Besides volatile oils, the main constituents of these plants are polyphenols. These compounds are secondary metabolites with multiple biological activities useful in the prevention and treatment of many disorders. **Aim**: To determine the flavonoids, hydroxycinnamic acids and total polyphenols content in several aromatic *Lamiaceae* plants available in Romanian pharmacies as herbal tea products*: Melissa officinalis, Lavandula officinalis, Rosmarinus officinalis, Mentha piperita, Thymus vulgaris* and *Salvia pratensis*. **Material and methods**: The quantitative determination of different types of polyphenols was performed in ethanolic extracts 70% and 50%, respectively, of each sample, using spectrophotometric methods. **Results and discussion**: The total polyphenols levels in the investigated products ranged between 3.10% and 6.51% (expressed as g GAE/100 g dry weight), the largest amount being identified in *Melissa officinalis* (6.51%). The samples of *Salvia pratensis* and *Mentha piperita* were the richest in flavonoid derivatives expressed as g rutin/100 g dry weight (1.83% and 1.53%, respectively), the optimal extraction being with 70% ethanol. The highest content in hydroxycinnamic acids expressed as g rosmarinic acid/100 g dry weight was found in *Melissa officinalis* sample (4.15%). **Conclusions**: There is a wide variability of polyphenolic content not only by species, but also depending on the polyphenols type or solvent used for extraction. The best extraction rate of total polyphenols in the investigated *Lamiaceae* species was obtained with 50% ethanol. **Keywords**: *LAMIACEAE*, POLYPHENOLS, QUANTITATIVE STUDY

Polyphenols are secondary plant metabolites characterized by high structural diversity and considerable potential biological action. Depending on the chemical structure there are ten main classes and among these, flavonoids and polyphenolic acids are the most abundant compounds. Antioxidant capacities represent one of the major biological properties of polyphenols, an intrinsic action as well as a possible mechanism to explain many other effects of these constituents (antiatherosclerotic, anti-inflammatory, and antitumor). As antioxidants, polyphenols protect cell constituents from oxidative damage, limiting the risk of oxidative stress-related diseases. Experi-

mental and epidemiological studies have highlighted the role of polyphenols in preventing cardiovascular disease, cancer, osteoporosis, diabetes and neurodegenerative diseases as well as aging (1).

The *Lamiaceae* family is one of the most important plant families comprising about 200 genera, of which 40% are aromatic plants (2). Although *Lamiaceae* species are known primarily for their volatile oil content, their therapeutic activities as well as other properties reflect the presence of other groups of chemical components, of which the most important are the polyphenols. Such compounds frequently encountered in *Lamiaceae* family are flavonoids and polyphenolic acids (mainly hydroxylcinnamic acids). Of the aromatic plants belonging to *Lamiaceae* family, the most popular and commonly used are: *Melissa officinalis* L. (lemon balm), *Lavandula officinalis* Chaix ex Vill. (lavender), *Thymus vulgaris* L. (thyme), *Mentha piperita* L. (peppermint), *Rosmarinus officinalis* L. (rosemary) and *Salvia pratensis* L. (meadow sage). These plants are mainly used for digestion stimulation, as spasmolytic, carminative and antimicrobial or antioxidant agents. The amount of polyphenols present in plants varies inter and intraspecifically, in the latter case depending on many factors, such as: area and harvesting time, origin (cultures or spontaneous flora), or processing methods including extraction type. Because polyphenols and volatile oils are bioactive markers for *Lamiaceae*, the content differences may lead to variations in therapeutic action (3).

The aim of this study was to determine the total amount of specific phenolic compounds (flavonoids, hydroxycinnamic acid derivatives, and total polyphenols) in alcoholic extracts obtained from several aromatic *Lamiaceae* plants available in Romanian pharmacies as herbal tea products. To estimate the true level of these compounds in plants, 50% and 70% ethanol was used as extraction solvent, given the fact that a better overall extractability for a wide spectrum of polyphenols can be obtained using hydro alcoholic solutions. This way, the quantitative variation of polyphenols was observed both in terms of species, but also depending on the solvent used for extraction.

MATERIAL AND METHODS

Chemicals and apparatus

All chemicals and reagents were analytical grade and were purchased from Sigma Aldrich Chemical Co. (Germany) and Merck (Germany). All spectrophotometric measurements were performed on ABLE-JASCO V 550 UV-VIS spectrophotometer.

Plant samples

Herbal tea products made from the leaves of *Melissa officinalis*, *Mentha piperita*, *Salvia pratensis*, *Rosmarinus officinalis*, flowers of *Lavandula officinalis* and aerial parts of *Thymus vulgaris* were purchased from local pharmacies. All samples were available in 50 g packets and come from the same manufacturer and same production year (2010).

Plant extraction

The plants (1 g) were ground into a fine powder in a mill and were extracted under reflux with 100 ml solvent, for 30 minutes. Then, extracts were filtered; after cooling, the filters were rinsed with the same solvent and the filtrates and rinsing were added in a volumetric flask and diluted ad 100 *ml*. For each sample, the extractions were performed using both ethanol 70% (v/v)

and ethanol 50% (v/v) as solvents. For the extraction of hydroxycinnamic acid derivatives the method described in European Pharmacopoeia 6th edition (*Melissae folium* monograph) was used (4).

Quantitative investigations

Before performing the quantitative determinations the polyphenolic spectrum was established. Thus, rutin and luteolin-7-glucoside are the major flavonoids and rosmarinic and caffeic acids are the predominant hydroxycinnamic acid derivatives in all samples.

- Determination of flavonoids

It was performed by a spectrophometric method based on the formation of yellow colored complexes with aluminium chloride, according to Romanian Pharmacopoeia 10th edition. Optical density was measured at a wavelength of 430 nm. Rutin was chosen as standard. The calibration curve was performed using rutin in the concentrations range of 4-16 μg/ml. The total flavonoid content was expressed as g rutin/100 g dry plant material (5).

- Determination of hydroxycinnamic acids

Total hydroxycinnamic acid derivatives were quantified in alcoholic extracts (ethanol 50%, v/v) using a European Pharmacopoeia 6th edition assay (*Melissae folium* monograph). The method is based on the formation of carmine red colored complexes in the presence of sodium nitrite and sodium molybdate, in alkaline medium. Optical density was measured at a wavelength of 505 nm. Rosmarinic acid was used as standard. The concentration range of rosmarinic acid for calibration curve was of 3-6 μg/ml. The amount of hydroxy-cinnamic acid derivatives was expressed as g rosmarinic acid/ 100 g dry plant material (4).

- Determination of total polyphenols

Total phenolic content of plant extracts was determined by Folin-Ciocalteau reagent (Singleton & Rossi method) using gallic acid as standard. Absorbance was measured at a wavelength of 765 nm. A standard curve was calculated using gallic acid concentrations in the range of 0.39-12.5 μg/ml. The results were expressed as gallic acid equivalents (GAE) (g gallic acid per 100 g dry plant material) (6).

All determinations were performed in triplicate and results are presented as means ± standard deviations.

RESULTS

Dependening on the extract type, flavonoids content varied between 0.35% and 1.83% for the 70% ethanolic extracts, and between 0.83% and 1.78% for the 50% ethanolic extracts (table I). The flavonoids were present in greater amounts in both extracts obtained from *Salvia pratensis* (1.83%; 1.78%) and *Mentha piperita* tea products (1.53%; 1.41%). Also, the level of hydroxycinnamic acid varied widely (0.43%-4.15%) between investigated species, the highest amount was found in *Melissa officinalis* (4.15%), followed by *Rosmarinus officinalis* (1.96%) (tab. I).

The total polyphenols amount ranged from 3.6 to 5.16 g GAE/100 g dry weight in 70% ethanolic extracts, while in 50% ethanolic extracts it varied between 3.10 to 6.51 g GAE/100 g dry weight (table II); 50% ethanolic extracts of *Melissa officinalis*, *Rosmarinus officinalis* and *Salvia pratensis* are polyphenol richest products (6.51%, 5.09% and 4.59%, respectively). Both ethanolic extracts of *Lavandula officinalis* had the lowest content of polyphenols (3.07%; 3.10%).

TABLE I

Flavonoids and hydroxycinnamic acid derivatives content (%) in *Lamiaceae* extracts

Sample	Total flavonoids (g rutin/ 100g dry weight)		Total hydroxycinnamic acids (g rosmarinic acid /100g dry weight)
	70% ethanol (v/v)	50% ethanol (v/v)	
Melissa officinalis	0.76±0.01	0.83±0.00	4.15±0.05
Lavandula officinalis	0.35±0.01	0.42±0.00	0.51±0.06
Mentha piperita	1.53±0.00	1.41±0.00	0.80±0.07
Thymus vulgaris	0.94±0.03	1.26±0.03	0.43±0.08
Salvia pratensis	1.83±0.00	1.78±0.01	0.63±0.09
Rosmarinus officinalis	0.97±0.00	1.02±0.00	1.96±0.17

TABLE II

The percentage amount of polyphenols in *Lamiaceae* extracts

Sample	Total polyphenols (g gallic acid/100 dry weight)	
	70% ethanol (v/v)	50% ethanol (v/v)
Melissa officinalis	5.16±0.01	6.51±0.01
Lavandula officinalis	3.07±0.01	3.10±0.01
Mentha piperita	4.11±0.06	4.32±0.07
Thymus vulgaris	3.67±0.03	4.56±0.04
Salvia pratensis	3.72±0.11	4.59±0.03
Rosmarinus officinalis	4.01±0.06	5.09±0.10

DISCUSSION

Polyphenols are metabolites of particular interest in determining antioxidant properties and other biological activities of *Lamiaceae* species. The polyphenols level found in the investigated species is relatively good, but modest compared to values reported in literature for *Mentha piperita* (6-12%) and *Lavandula officinalis* (5-10%) (1). Apart from *Mentha piperita* and *Salvia pratensis*, in the investigated species flavonoids are minor components of the polyphenolic spectrum, accounting for less than 30%. Also, hydroxycinnamic acid derivatives represent less than 20% of the polyphenolic distribution, except for *Melissa officinalis* (over 60%) and *Rosmarinus officinalis* (over 30%). For each plant, the use of 50% ethanol lead to better extractibility of total polyphenols, in most species the increase exceeding 20%. In the case of *Mentha piperita* and *Salvia pratensis* species, a larger amount of flavones was extracted using 70% ethanol, probably due to the presence of more pronounced lipophilic structures (methoxylated flavonoids). In the leaves of *Melissa officinalis*, European Pharmacopoeia requires a minimum content of 4.0% of hydroxycinnamic derivatives, expressed as rosmarinic acid, so that the investigated sample corresponds to pharmacopoeia

requirements (4).

CONCLUSION

The quantitative composition of polyphenols varies greatly between investigated *Lamiaceae* species. *Salvia pratensis* and *Mentha piperita* samples are the richest in flavonoid derivatives, the optimal extraction being with 70% ethanol. The highest content in hydroxycinnamic acids is found in 50% ethanolic extracts of *Melissa officinalis* and *Rosmarinus officinalis* plants. The *Lavandula officinalis* sample shows the lowest levels of flavonoids and total polyphenols, in both 70% and 50% ethanolic extracts. The solvent that provides a better extraction of total polyphenols in the investigated *Lamiaceae* species is 50% ethanol.

OLMESARTAN HEXETIL: A NEW ESTER PRODRUG OF OLMESARTAN

A new prodrug of olmesartan named olmesartan hexetil was synthesized. In vitro and in vivo studies were performed on olmesartan hexetil in comparison to olmesartan medoxomil, a known prodrug of olmesartan with long-lasting antihypertensive activity. The olmesartan hexetil exhibited higher effects than olmesartan medoxomil, probably due the hexetil moiety that increased lipophilicity. The new prodrug was rapidly hydrolyzed to olmesartan in rat liver microsomes and plasma. In vivo studies on male rats showed a good absorption from gastrointestinal tract. The pharmacokinetic parameters values were higher than those of olmesartan medoxomil. The results are intended to be a promise for the discovery of a new angiotensin receptor blockers effective in the treatment of hypertension (El-Gamal MI, Anbar HS, Chung HJ et al. Discovery of olmesartan hexetil: a new potential prodrug of olmesartan. Bioorg Med Chem Lett 2013; 23: 1347-1350).

EFFICACY OF ANTIBIOTIC PROPHYLAXIS FOR PREVENTING INTRATHORACIC INFECTIONS AFTER THORACOSTOMY FOR TRAUMATIC HAEMO/PNEUMOTHORAX – EXPERIENCE OF ORADEA COUNTY EMERGENCY HOSPITAL

D. Grigorescu[1], A. Maghiar[2]

2. Department of Surgery

EFFICACY OF ANTIBIOTIC PROPHYLAXIS FOR PREVENTING INTRATHORACIC INFECTIONS AFTER THORACOSTOMY FOR TRAUMATIC HAEMO/PNEUMOTHORAX –EXPERIENCE OF ORADEA COUNTY EMERGENCY HOSPITAL (Abstract): The **aim** of the paper is to observe the effectiveness of prophylactic administration of antibacterials against empyema and pneumonia after tube thoracostomy for traumatic collections. **Material and methods:** Observational retrospective study over a ten years period (2002-2011), at the Oradea County Emergency Hospital on 939 patients with chest tube drainage for traumatic haemo/pneumothoraces. The morbidity by intrathoracic infections was 5,5% in the curative antibiotic group. **Results:** The median number of risk factors for surgical infections and case severity were not statistically different (*p=0.9653 and p=0,6601*) between cases with antibioprophylaxis and curative treatment, but the incidence of intrathoracic infection in the prophylaxis group (n=86) was half (2,3%). Antibioprophylaxis was effective in over 95% of the cases and it associated in-hospital length of stay, length of stay in the ICU and costs of care significantly (*p<0.0001, p<0.0001, p=0.0046*) lesser than of those patients treated with curative regimen. The overall mortality was 8.6% within the curative regimen group with an attributable mortality to infections of 17.39%; but it was only 2.3% and respectively 0 within the prophylaxis group. **Conclusions:** Antibiotic prophylaxis for intrathoracic infections after tube thoracostomy for traumatic collections was justified by case severity and risk factors and was effective and cost-efficient, but it should be administered selectively. **Keywords**: ANTIBIOPROPHYLAXIS, TUBE THORACOSTOMY, TRAUMA, INTRATHORACIC INFECTIONS.

The literature oscillates between the opinion that antibioprophylaxis after tube thoracostomy for traumatic collections lowers the incidence of empyema and pneumonia(1) as opposed to non-administration of antibacterials, and the finding that administrated before, during or after tube thoracostomy the antibacterials do not change the outcome(2). Some authorities consider that the level of evidence is good enough to recommend prophylaxis for pneumonia, but not for empyema (3). More recent studies are encouraging the use of prophylaxis by some institutions; meanwhile others remain very selective with this indication (4, 5). The benefit from the antibacterial must be

significant, because of the risk of bacterial resistance generation and dissemination with excessive use of antibacterial drugs (6).

MATERIAL AND METHODS

The study is a retrospective observational review over ten years (2002-2011) conducted in the Emergency County Hospital Oradea, on all admitted trauma patients who underwent tube thoracostomy for haemo/pneumothorax, exclusively on those who needed urgent thoracostomy in the first 48 hours. We identified the risk factors for infection after a selected (7, 8, 9, 10, 11) list (COPD, TB, diabetes mellitus, heart diseases, liver diseases, renal diseases, neoplasms, alcohol consumption, obesity, age over 65 years, leucocytosis, polytrauma, multiple rib fractures or flail chest, more than one chest drain) and their association with antibacterial prescriptions, surgical procedures, intrathoracic infections (pneumonia/empyema) and with mortality. We retrospectively noticed the prescribing and non-prescribing of antibacterial drugs and pneumonia and/or empyema developing after 48 hour from tube thoracostomy. We considered as prophylactic regimen the prescribing of one antibacterial drug in one or two doses or at most for 24 hours, and as curative regimen, the prescribing of one antibacterial for more than 24 hours or the prescribing of more than one antibiotic drug. We compared the in-hospital length of stay, the length of stay in the ICU, the morbidity by intrathoracic infections and the mortality, respectively after the prophylactic administration, the curative administration and the non-administration of antibacterial drugs.

As the dedicated trauma severity scores (AIS, ISS) were used neither in prehospital nor in the hospital settings and as also the physical/physiological status scores (ASA, APACHE) were not consistently evaluated in all patients, we assessed the severity of cases as the presence of serious traumatic lesions in more than one anatomical region of the body (polytrauma).

The statistical analysis was performed with the MedCalc program, version 9.4.3.0 (MedCalc Software, Mariakerke, Belgium). The results were represented as the 'null' hypothesis presence probability (*p*), with the *p value* <0.05 proving the statistical significance of the difference between variables.

RESULTS

In our hospital, between 01.01.2002 and 31.12.2012 were admitted 939 patients with thoracic trauma who underwent closed chest tube thoracostomy with the intent of definitive treatment for haemo/pneumotoraces. Ninety-eight percent of the patients suffered a blunt chest trauma (n=922). Most of the 654 patients (70%) were prescribed antibacterial drugs in curative regimen; 86 of them (9%) were prescribed antibiotics in prophylactic regimen, and 199 (21%) received no antibacterial agents. But only 78 of 654 (12%, *p<0.0001 Chi-square test*) of those who received antibacterial agents in curative regimen had a diagnosis of infection or solid evidence of infection documented in their paper forms, such as the presence of pus in respiratory aspirates or pleural fluid, the identification of pathogen strains in the biologic specimens, or sensitivity test results.

The logistic regression analysis showed that two risk factors were statistically significant associated with the antibiotic prescription (n=740): leucocytosis [OR 4.3584 (CI 95%: 2.05-9.26) *p=0.0001*] and polytrauma [OR 1.9032 (CI 95%:1.22-2.96) *p=0.0045*].

Morbidity. We found 42 septic complications (21 pneumonias and 21 empyemas) in 40 patients (4.24%), with 2 patients associating both of the infections. Of all 40 infected cases, 34 (85%) were cured by treatment and 6 died (15%). In the non-antibiotic group of patients (n=199), 2 manifested empyema, and 2 of those who received antibiotic prophylaxis also suffered of intrathoracic infections after the pleural drainage. The rest of 36 of the infected patients (90%) belonged to the curative antibiotic group. The infectious morbidity with pneumonia/empyema in the curative group was 5.5%, in the prophylaxis group was 2.3% and in the non-antibiotic group was 1%. The patients with septic complications had longer mean hospital stay: 18 days (CI 95%:14.5-21.5) comparative to 9 days (CI 95%:8-9) (*p<0.0001 Mann-Whitney test*), and median costs of care higher than uninfected patients: 5184RON (CI 95%: 2303-8616) comparative to 2588 RON (CI 95%: 2445-2769). (*p<0.0001 Mann-Whitney test*)]. The retrospective analysis with logistic regression did not find the prophylactic or curative antibiotic prescribing to lower the risk for infection outcomes (pneumonia and empyema) (OR=0.4087; CI 95%: 0.09-1.72).

Mortality. There were 28 deaths (3%) in ten years. In the curative treatment group died the largest number (23 deaths) of patients (82%), 4 of those died with intrathoracic infections. The overall mortality in this group was 3.5%, and the specific mortality by intrathoracic infections was 17.39%. In the non-antibiotic group the overall mortality was 1.5% (3 deaths), with no deaths due to infections. In the prophylaxis group the overall mortality was 2.3% (2 deaths) and no specific infectious mortality. Among the patients with intrathoracic infections the mortality was 15%. Mortality was statistically significant more frequently associated with two risk factors: the polytrauma condition [OR=19.898; CI 95% (6.81-54) *p=0.0001*] and age over 65 years [OR=2.5080; CI 95% (1.06-5.88) *p=0.0045*].

Prophylaxis. Two patients in the prophylaxis group suffered intrathoracic infections and were converted to curative antibacterial regimen with successful recovery. Eighty-two of 86 of the patients with antibiotic prophylaxis (>95%) were discharged in good recovery. The median hospital length of stay of the prophylaxis patients was 7.5 days (CI 95% 7-8), the median length of stay in ICU was 1 day (CI 95% 1-1), and the cost of care was 2196 RON (CI 95%: 1879-2842) and all the three variables were significantly lesser than those for the curative group (*p<0.0001, p<0.0001 and p=0.0046* respectively *Mann-Whitney test*). Although the prophylaxis patients also had lesser lengths of stay in the ICU than the non-antibiotic patients, the median cost of care did not significantly differ between the prophylaxis and non-antibiotic groups (*p=0.1584 Mann-Whitney test*).

DISCUSSION

Tube thoracostomy is the definitive treatment for 85-90% of the chest trauma patients (3, 4, 15). Trauma lowers immunity, jeopardizes tissues making them vulnerable to infection and contaminates spaces that are normally sterile. Thoracostomy itself may care intrathoracic infection either by procedural contamination or by missing complete evacuation of the pleural collections that secondary become infected (1, 3). The incidence of pneumonia and bacterial empyema after closed tube thoracostomy is reported as

2-35% and carries mortality as high as 30% (12, 13). Forty percent of the traumatic haemo-thoraces, complicated by respiratory insufficiency, empyema or fibrothorax will need thoracostomy with the associated morbidity (14, 15).

The curative prescribing of the antebacterials is justified by infection or by penetrating contaminated or grossly dirty wounds (16, 17, 18). In our hospital the prescribing of antibacterials is strongly associated with leucocytosis (neutrocytosis) and with polytrauma. The risk of prescribing antibiotics was 4,3 times higher in the presence of leucocytosis and 1.9 times higher in the presence of polytrauma. But it is well known the fact that trauma is an activator of the systemic and local inflammatory response and that the activation and mobilization in great numbers of inflammatory white blood cells both in the circulatory torrent and organs (affected or not by lesions), in trauma setting does not imply infection or antibacterial fight (16,17,19), without pertinent evidence of the presence and multiplication of bacteria. In these cases, white blood cell count based antibacterial prescribing is not justified without other arguments (19). Should the antibiotic be mandatory, only the prophylactic regimen was justified (20). The polytrauma setting by severity may involve not only ventilatory but also haemodynamic assisting or control, circumstances that may elicit preventing infection, but also only in a prophylactic regimen (16, 19, 20).

The incidence of one intrathoracic infection at every 25 tube thoracostomies for trauma over ten years would intuitively demand 25 antibacterial prophylactic administrations in order to avoid one infection. But actually it would be justified to select patients for prophylaxis instead of routine prophylaxis. In fact, the morbidity by empyema and pneumonia was 1% in the non-antibiotic group but more than double (2.3%) in the prophylaxis group which means more than superfluous prophylaxis. That is why the actual study suggests selective prophylaxis.

CONCLUSIONS

Antibiotic prophylaxis for intrathoracic infections after tube toracostomy for traumatic haemo/pneumothoraces was justified in the presence of the risk factors and case severity and demonstrated efficacy and cost effectiveness.

Antibiotic prophylaxis in our hospital should be selective with this indication.

Unjustified antibacterial therapy in curative regimen must be abandoned because of the useless and long exposure of hospital pathogens to antibacterials, with emerging and dissemination of bacterial resistance. In trauma setting, the antibacterials are adjuvants for the treatment, while in pneumonia they are the basic treatment, and the loss of the effectiveness of the basic treatment of nosocomial pneumonia would become (again) an immense danger concerning the actual mortality of 30% or more.

MAIN NEUROENDOCRINE FEATURES AND THERAPY IN PRIMARY SLEEP TROUBLES (Abstract): Insomnia is a sleep trouble in which the patient has difficulties in falling or in staying asleep. There are patients who fall asleep easily, but wake up too early; others have troubles in falling asleep and a third category has troubles with both falling and staying asleep. Independent of the type of insomnia, the final result is a poor-quality sleep, responsible for depressive or irritable mood, loss in concentration, learning and memory capacities. Sleep is essential to emotional and physical health. Inadequate sleep over a period of time is increasing the risks for obesity, diabetes, heart disease and depression. People suffering of chronic insomnia show an increased predisposition for psychiatric problems. People who had sleep troubles reported impaired ability to fulfill tasks involving memory, learning, logical reasoning and mathematical operations. New studies show that insomnia might be a result of the decrease of gamma-aminobutyric acid (GABA), a neurochemical responsible for the decrease of activity in many brain areas. Lower brain GABA levels were also found in people with major depressive disorder and anxiety disorders. Hypnotics, such as benzodiazepines are acting increasing the activity of the GABA neurons. Exposure to stress is associated with a greater risk for insomnia, with individual differences. Stress activates the sympathetic nervous system and the hypothalamic-pituitary-adrenal (HPA) axis. Increased activity of HPA axis is stimulating the secretion of corticotropin-releasing hormone, further inducing sleep disruption. Insomnia is also associated with depression and anxiety disorders, in which the HPA axis is characteristically overactive. People who show predisposition to sleep troubles have a hyperactive sympathetic nervous system, they are usually suffering from hyperarousal and they have a more intense response to stressful events. Primary sleep troubles (insomnia) has no apparent causes, is lasting more than one month, and is affecting approximately a quarter of the adult population. Secondary insomnia is associated with chronic heart and/or lung diseases, medication which interfere with onset or duration of sleep, constant change of the sleep habits, restless leg syndrome, etc. Besides lifestyle changes and cognitive-behavioral therapy, in the treatment of insomnia are used hypnotic medicines, advised to be prescribed on short-term cures of one or two weeks. Benzodiazepines are inducing and maintaining sleep. Longer use is responsible for severe side effects – dependency and withdrawal syndrome, daytime drowsiness and dizziness, low blood pressure, memory troubles and change in the melatonin secretion during night-time period. For these reasons were created non-benzodiazepines hypnotics – zolpidem, zaleplon, which are as effective as benzodiazepines, but have fewer side effects. Nevertheless the use of these hypnotics is also restricted to 7 – 10 days. Zopiclone (Imovane) another short-acting non-benzodiazepine hypnotic

has a different chemical structure, but a pharmacologic profile similar to that of the benzodiazepines; the treatment should be of maximum four weeks. Besides generally known concerns related to the use of hypnotics (residual sedative effects, memory impairment, rebound insomnia, abuse, dose escalation, dependency and withdrawal problems) it was signaled a risk of death associated with the use of current hypnotic medications. **Key words:** SLEEP TROUBLES, INSOMNIA, HYPNOTIC MEDICATION

DEFINITION, OCCURENCE, TYPES, SYMPTOMS AND RISKS OF PRIMARY SLEEP TROUBLES

Insomnia is a sleep trouble characterized by the difficulty in falling or in staying asleep. There are patients who fall asleep easily, but wake up too soon, others have troubles in falling asleep and finally, the third group has troubles with both falling and staying asleep. Indifferent of the type of insomnia, the result is a poor-quality sleep. This situation is responsible for an inactive mind along the day and the lack of refreshness after sleep. In this view, insomnia is the most common cause of depressive or irritable mood, loss in concentration, learning and remembering. Sleep is essential to physical and emotional health. Inadequate sleep over a period of time is associated with obesity, diabetes, heart disease and depression (Stores 2007, Schroeder 2005). Emotional and mental benefits of sleep are significant. Some people with chronic insomnia show an increased predisposition for psychiatric problems. People who had sleep troubles reported impaired ability to fulfill tasks involving memory, learning, logical reasoning and mathematical operations (Estivill 2003).

In contrast with the secondary insomnia, which is related with other diseases or troubles, being the most common type, the primary insomnia appears without any coexisting cause, it lasts at least one month and is found at approximately a quarter of the adult population. Secondary insomnia is found in eight people of ten with insomnia. Some of the major causes of secondary insomnia are – heart and/or lung chronic diseases, medicines which interfere with onset or duration of sleep, substances like caffeine, tobacco and alcohol, constant change in sleep routine or a poor sleep environment, restless legs syndrome. Main symptoms associated with insomnia are poor concentration, impaired motor coordination and memory troubles, depressive or irritable mood (Silber 2005, Sateia 2009, Panossian 2009).

NEUROENDOCRINE FEATURES OF THE PRIMARY SLEEP TROUBLES

Many adults suffering from insomnia complain of an inability to “shut down” their mind at night. New studies show that this is a result of the decrease of gamma-aminobutyric acid (GABA). People with primary insomnia with more than six months have 30 % less GABA, a neurochemical responsible for the decrease of activity in numerous brain areas. Lower brain GABA levels have also been found in people with major depressive disorder and anxiety disorders. Primary insomnia has a lot of features in common with these conditions, being as well a critical risk factor (Winkelman 2009, Riemann 2003, Roth 2007). In this view, the GABA deficiencies found in people with mood and anxiety

disorders, might be linked to sleep disturbances. Many hypnotic medications, most effective in treating insomnia, are benzodiazepine receptor antagonists (BzRAs) which increase the activity of the GABA neurons. Besides sleep, GABA is involved in cognitive, memory and psychomotor functions.

Exposure to stressful events is usually associated with a greater risk for insomnia, with individual differences. Stress factors activate the sympathetic nervous system and the hypothalamic-pituitary-adrenal axis (HPA). In insomniacs there is an increased activity of HPA axis, which by secretion of corticotropin-releasing hormone is further producing sleep disruption. Sleep loss is also activating HPA axis. Insomniacs have reduced melatonin levels at night, while corticotropin-releasing hormone was demonstrated to reduce nocturnal melatonin levels, in normal subjects (Passarella 2008).

These data suggest that HPA hyperactivity may be involved in neuroendocrine changes that lead to insomnia. Furthermore, insomnia is associated with depression and anxiety disorders, in these illnesses the HPA axis is characteristically hyper activated. People which show predisposition to sleep troubles have an overactive sympathetic system; they are more likely to suffer from hyper arousal and have a more intense response to stressful events (Benca 2005, Roth 2007).

THERAPY OF THE PRIMARY SLEEP TROUBLES

Treatment options for insomnia include lifestyle changes, cognitive-behavioral therapy and sleep or hypnotic medications. Lifestyle changes are focusing on good sleep habits: dark and quiet bedroom, with adequate temperature; avoidance of overintake of caffeine, alcohol, tobacco or other stimulants; avoidance of medicines that disrupt sleep; stable bedtime habits – going to bed at the same hour. Cognitive-behavioral therapy includes relaxation training and biofeedback at bedtime, to reduce anxiety; positive thinking and replacing worries related to falling asleep; talking to therapists; reduction of time spend in bed while awake (Smith 2002, Morin CM 2009). Usually, sleeping pills are prescribed only for one or two weeks, helping to establish a regular sleep schedule. Sleep medication can become habit-forming, thus it is considered that sleep medication works best as a short-term treatment, combined with lifestyle and behavior changes.

Benzodiazepines are used for short-term relief from insomnia. They induce sleep and they maintain sleep. Examples such as diazepam (Valium), lorazepam (Activan) or quazepam (Doral) have troubling side effects – dependency and withdrawal syndrome, daytime drowsiness and dizziness, low blood pressure, especially in older people and memory troubles (Cotroneo 2007). They affect the melatonin secretion, during the night-time period (Garfinkel 1999). Using such hypnotics may also worsen sleep apnea and other breathing disorders (Budur 2007, Schutte-Rodin 2008).

Zopiclone (Imovane) is a short-acting hypnotic. Zopiclone is a cyclopyrrolone derivative, with a structure unrelated to other hypnotics. However, the pharmacologic profile of zopiclone is similar to that of the benzodiazepines. In sleep laboratory, studies of one to 21 days duration in man, the hypnotic reduced sleep latency, increased the sleep-duration and reduced the

number of nocturnal awakenings. Zopiclone delayed the onset of REM sleep, but did not reduce consistently the total duration of REM periods. The course of treatment should be of maximum 4 weeks as duration. The most common adverse reaction of zopiclone is taste alteration (bitter taste). Drowsiness, dizziness, somnolence, asthenia, may be signs of intolerance or excessive doses (Dundar 2004). Non-benzodiazepines hypnotics, zolpidem and zaleplon are short-acting, being as effective as benzodiazepines. They have fewer side effects and lesser withdrawal symptoms. They are used as alternative therapy and to treat the dependency and withdrawal problems induced by benzodiazepines. However the use of these hypnotics is also restricted to 7 – 10 days. Some studies have signaled dependency and withdrawal symptoms with these medicines too. Expert opinion is strongly against long-term drug treatment because of possible residual sedative effects, memory impairment, falls, respiratory depression, rebound insomnia, abuse, dose escalation, dependency and withdrawal difficulties and an increased risk of death possibly associated with the use of current hypnotic medications (Wagner 2000, Barbera 2005, Morin A K 2007).

IMPULSIVITY COULD BE DECREASED BY HIGHER DOPAMINE LEVELS

Dopamine is a neurotransmitter that plays a key role in motivations, mood, learning, cognition, behavior and attention. Higher levels of dopamine in the frontal cortex of the brain decrease impulsivity, according to a study conducted by Kayser et al. Impulsivity characterizes subjects with frontal lobe damage and behavioral disorders and is a common risk factor associated with substance abuse. To test the hypothesis that lower dopamine in the frontal cortex contributes to impulsivity by impairing corticostriatal function, researchers performed a randomized, double-blind, placebo-controlled study in which they administered the brain penetrant catechol-O-methyltransferase inhibitor tolcapone or placebo to healthy subjects performing a delay discounting task. The results of the study showed that tolcapone significantly increased choice of delayed monetary rewards and also changed corticostriatal connectivity by inducing a decrease in the coherence between ventral putamen and pregenual cingulate cortex. In conclusion, the study states that raising cortical dopamine levels attenuates impulsive choice by changing corticostriatal function (Kayser AS, Allen DC, Navarro-Cebrian A et al. Dopamine, corticostriatal connectivity, and intertemporal choice. *J Neurosci* 2012; 32(27): 9402-9).

CURRENT MICROBIOLOGICAL DATA ON LOWER RESPIRATORY TRACT INFECTION IN CYSTIC FIBROSIS. PART I: MICROORGANISMS ISOLATED AND THEIR CLINICAL SIGNIFICANCE (Abstract): Cystic fibrosis (CF) is a disease that degrades the local defense mechanisms of the lower respiratory tract. As a result, patients develop recurrent infections that progressively deteriorates antiinfection defenses and represent the major cause of mortality. A hallmark of those infections is the diversity of microorganisms isolated from broncho-alveolar lavage or sputum. The clinical significance of isolates is different, the recognition of the role in altering of respiratory function being important in guiding antibiotic therapy. Current data support pathogenicity in CF of *S. aureus*, *P. aeruginosa* and *B. cepacia* complex, the latter two being considered "preterminal bacteria". *S. aureus* was the most common cause of mortality and morbidity in preantibiotic era. Today, life expectancy was improved with the introduction of antistaphylococcal antibiotics. Hypermutation of *P. aeruginosa* - the most common species isolated from patients with CF, is the essential factor in the development of multi-resistance to antibiotics. *As P. aeruginosa, B.cenocepacia* is a virulent species that cause infections with poor prognosis. Microorganisms with secondary role *(H. influenzae, S. maltophilia*, atypical Mycobacteria, *Aspergillus* spp) whose clinical significance has not been clarified yet, require further studies. **Key words**: CYSTIC FIBROSIS, RESPIRATORY TRACT INFECTION, MICROBIAL PATHOGENS, CLINICAL SIGNIFICANCE

Fibroza chistică (FC) este o afecțiune congenitală care degradează, încă din perioada de sugar, mecanismele de apărare locală ale tractusului respirator inferior (TRI): secreția de mucus capătă o consistență vâscoasă şi *clearance*-ul muco-ciliar devine nefuncțional. Ca o consecință, pacienții dezvoltă repetate infecții acute, care într-o etapă mai tardivă devin cronice cu exacerbări, ce deteriorează progresiv apărarea antiinfecțioasă şi constituie cauza majoră de mortalitate prin insuficiență cardiopulmonară. Progresele recente în domeniu au condus la prelungirea vârstei la care apare declinul ireversibil al funcției respiratorii.

O particularitate a acestor infecții este reprezentată de diversitatea microorganis-

melor izolate din lavajul bronho-pulmonar sau spută, în diverse asociații, care variază în raport cu vârsta pacienților. Semnificația clinică a izolatelor este diferită, recunoaşterea rolului jucat de anumite specii în alterarea funcției respiratorii fiind importantă în orientarea antibioterapiei. În plus, în infecția cronică apar modificări fenotipice la unele tulpini, ceea ce determină dificultăți în identificarea acestora la nivel de specie prin metode convenționale.

Pe baza unor sinteze recente din literatură (1, 2, 3) şi a numeroase studii publicate în ultimii ani, ne-am propus să detaliem mai jos aceste aspecte cu impact în ameliorarea diagnosticului microbiologic, al strategiei terapeutice şi măsurilor de prevenție.

Staphylococcus aureus este, din punct de vedere istoric, prima specie asociată cu infecția TRI la pacienții cu FC, care poate determina infecții acute şi cronice, responsabile de amplificarea răspunsului inflamator local. În perioada preantibiotică a reprezentat cea mai frecventă cauză de morbiditate şi mortalitate la copilul de vârstă mică, speranța de viață fiind ulterior ameliorată odată cu introducerea antibioticelor antistafilococice.

Colonizarea nazală cu *S.aureus* este un factor de risc pentru infecții ulterioare pulmonare cu acelaşi genotip (4). Sunt autori care susțin că profilaxia continuă cu antibiotice determină o reducere a numărului de spitalizări la copii sub vârsta de cinci ani, alții consideră că ar favoriza suprainfecția cu *Pseudomonas aeruginosa*, microorganism cu agresivitate mai importantă (5).

În ultimii ani a crescut progresiv frecvența infecțiilor determinate de tulpini meticilino-rezistente la toate vârstele, mai ales la adolescenți. Un studiu realizat în SUA a raportat o creştere a prevalenței de la 2,1% în 1996 la 17,2% în 2005 (6). Este posibilă transmiterea acestor tulpini între pacienți cu FC sau de la persoane fără această boală de fond; condițiile de spitalizare constituie un factor de risc. Date contradictorii apar în literatură privind consecințele pe termen lung ale infecțiilor cu tulpini meticilino-rezistente; infecțiile cu tulpini comunitare, recunoscut mai virulente, pot explica declinul mai rapid al funcției respiratorii (7, 8, 9).

De la pacienții tratați cu trimethoprim-sulfametoxazol sau aminoglicozide poate fi izolat un fenotip particular, *S.aureus* cu colonii mici, ce prezintă auxotrofism pentru hemină, menadionă sau timidină (10). Aceste tulpini se dezvoltă lent (după 48-72 ore) şi prezintă unele caractere întâlnite la stafilococii coagulazo-negativi: cultivă sub formă de colonii nehemolitice, nepigmentate, manito-negative, cu testul coagulazei pe lamă negativ (11); în aceste condiții există riscul de a nu fi depistate de microbiolog. Ele au fost izolate şi din alte infecții persistente şi recidivante ca osteomielite, artrite septice sau infecții tegumentare.

Pseudomonas aeruginosa este cea mai frecventă specie izolată din sputa pacienților cu FC, cu variații în raport de vârstă: aproximativ 30% la copii în primii 5 ani de viață şi peste 80% la adulți (4, 11, 12). La vârste mici este prezent intermitent, consecutiv tratamentului cu antibiotice sistemice şi locale. Infecțiile devin ulterior cronice, cu acutizări intermitente care la un moment dat apar refractare la tratament şi conduc la deces (13,14). Terapia precoce cu antibiotice, când infecția este pentru prima data detectată, are un efect benefic întrucât realizează eradicarea temporară a *P. aeruginosa* şi întârzie trecerea spre infecția cronică (15).

În stadiul cronic, sub efectul stresului oxidativ, sunt izolate tulpini modificate,

consecutiv unor mutații, care sintetizează în exces o matrice extracelulară din alginat ce le conferă avantaje adaptative la condițiile locale: aderență sporită la suprafața epiteliului respirator, rezistență la mecanismele de apărare (opsonizare, fagocitoză), acces redus al antibioticelor către celulele bacteriene ce poate explica în parte neconcordanța între sensibilitatea *in vitro* și răspunsul terapeutic (16, 17, 18, 19). Coloniile au un aspect mucos, lipsite de pigmentul caracteristic, prezența lor fiind recunoscută ca o cauză majoră a deteriorării pulmonare ("fenotip hipermutator"). Microbiologul va consemna prezența acestor colonii mucoide a căror izolare de la un pacient cu diagnostic neprecizat impune investigații pentru FC, indiferent de vârstă (13).

În plus, în infecțiile cronice, mai ales după tratamente cu tobramicină sau colistin în aerosoli, au fost izolate tulpini cu multiplicare lentă care dezvoltă colonii mici, dar relevanța clinică a acestora este neconcludentă (20). În cazul tulpinilor atipice, studii comparative au demonstrat că identificarea biochimică cu minigalerii API 20NE riscă să conducă la neconcordanțe semnificative în raport cu tehnicile moleculare (21, 22).

Hipermutația reprezintă factorul esențial în dezvoltarea multirezistenței la antibiotice (18, 23). În timp ce tratamentul prelungit cu agenți terapeutici anti-*Pseudomonas* este folosit pentru evitarea declinului rapid al funcției respiratorii, în paralel are loc selecția de mutanți rezistenți care sunt responsabili in final de eşec terapeutic. A fost dovedit că rata mutației genelor care controlează sinteza pompelor de eflux și producerea de beta-lactamaze la tulpinile "hipermutante" este mult mai mare decât la tulpinile sălbatice. În aceste condiții este recomandat ca în orice stadiu al bolii să se recurgă la asociații sinergice de antibiotice și nu la monoterapie.

În infecții cronice au fost descrise tulpini "epidemice" responsabile de *cross*-infecții, care necesită măsuri de control, cele mai eficiente fiind izolarea pacienților necolonizați de cei infectați (4, 24, 25).

***Burkholderia cepacia* complex** (BCC) este un grup taxonomic care cuprinde în prezent 17 specii identificate prin tehnici moleculare, diferențierea pe baza caracterelor fenotipice prezentând un risc crescut de eroare (22, 26). Sunt bacili gram-negativi cu habitat în mediul extern (sol și plante), unii fitopatogeni, rar prezenți în infecții la om. *B.cenocepacia* și *B.multivorans* sunt cel mai frecvent izolate de la pacienții cu FC, prevalența cea mai mare, de aproximativ 5%, fiind înregistrată la adulți cu vârsta de 18-25 ani (6, 17, 27). Utilizarea mediilor selective a crescut şansa de izolare a acestora (28).

În general, prognosticul acestor infecții este sever: infecții cronice pulmonare evoluează cu episoade de exacerbare mai ales în faza tardivă a bolii pe care o agravează (aproximativ un sfert dintre bolnavi mor în primul an de la debutul acestei infecții). Dintre speciile din BCC, *B.cenocepacia* este considerată cea mai virulentă, dar pacienții pot fi colonizați cu tulpini cu patogenitate diferită, ceea ce face dificilă o predicție a evoluție. Perioadele de acutizare nu s-au dovedit a fi determinate de achiziția unei alte tulpini decât cea inițială (17, 29).

BCC prezintă niveluri înalte de rezistență la majoritatea antibioticelor, după cure repetate putând fi selectate clone panrezistente (11). Studii de tipare moleculară au evidențiat transmiterea unor tulpini între pacienți spitalizați, dar în infecții cu *B. multivorans* sunt recunoscute surse în special din mediul natural. Măsurile de control

al acestor infecții depind de capabilitatea laboratorului de a izola şi identifica aceste bacterii.

La aproximativ 20% dintre cei infectați poate să apară o formă clinică severă numită "sindromul cepacia" care evoluează cu pneumonie gravă, bacteriemie şi deces (4, 11, 30). În Marea Britanie şi Canada a fost descrisă o clonă, ET12 (*electrophoresis type* 12), înalt patogenă şi transmisibilă, responsabilă de infecții rapid fatale.

Ca şi *P.aeruginosa*, specii BCC au potential de a produce în exces un polizaharid extracelular (diferit chimic de alginat) dar aceste tulpini mucoide sunt considerate mai puțin virulente. Conversia fenotipului mucoid în non-mucoid a fost indusă *in vitro* sub efectul ciprofloxacinei şi ceftazidimei dar nu cu meropenem (31).

De menționat o altă specie, *B.gladioli*, foarte asemănătoare fenotipic cu BCC, capabilă să determine mai ales colonizări tranzitorii (32). Medii selective folosite în izolarea BCC care conțin gentamicină inhibă dezvoltarea acestei specii.

***Stenotrophomonas maltophilia* şi alți bacili gram negativi nefermentativi** (*Achromobacter* spp, *Pandoraea* spp, *Ralstonia* spp, *Inquilinus limosus*). Sunt bacterii ubicvitare, dificil de identificat la nivel de specie prin teste biochimice (21). Au fost izolate în FC din probe de spută, precum şi în alte tipuri de infecții de predilecție la imunocompromişi (6, 4, 33, 34). Prezența în căile respiratorii poate fi inițial tranzitorie, dar *S.maltophilia* şi *A. xylosoxidans* au fost puse în evidență în faza avansată a bolii, când pacienții devin cronic colonizați (2). Mai mulți autori pun în discuție semnificația clinică a acestora (11, 17, 35, 36, 37); un studiu recent consideră că infecțiile cronice (nu şi colonizări intermitente) cu *S. maltophilia* reprezintă un factor de risc pentru exacerbările pulmonare (38).

Haemophilus influenzae a fost izolat cu o frecvență de aproximativ 20% la copii cu FC sub vârsta de 1 an, 32% între 2-5 ani iar la adulți sub 10% (6). Aceste date urmează dinamica colonizării la purtători, ceea ce impune criterii cantitative de diagnostic care să diferențieze infecția de contaminarea cu flora oro-faringiană. În ambele condiții sunt prezente tulpini necapsulate, neinfluențate de vaccinul anti-*H.influenzae*. Deşi este luat în discuție rolul real al acestei specii în FC, majoritatea clinicienilor tratează exacerbările acute cu antibiotice (11).

Streptococcus pneumoniae, un recunoscut patogen implicat în infecții ale TRI, este rar izolat de la pacienți cu FC (1, 35).

Micobacterii atipice. FC nu reprezintă un risc pentru infecția cu *Mycobacterium tuberculosis* dar în ultimii 20 ani a sporit numărul cazurilor colonizate sau cu infecții determinate de micobacterii atipice. Un studiu multicentric din SUA a evidențiat o prezență a acestora prin examene microscopice şi culturi repetate în medie la 13% (7-24%) din cazuri, asociate cu modificări radiologice (39). Au fost izolate de la toate grupele de vârstă dar prevalența este semnificativ mai joasă înainte de 15 ani. Pacienții sunt în special adulți cu funcție respiratorie bună, care prezintă concomitent infecții pulmonare cu *S.aureus* şi mai rar cu *P.aeruginosa*.

M.avium complex *şi M.abscessus* sunt cel mai frecvent izolate; *M.abscessus* este întâlnit la toate grupele de vârstă în timp ce *M.avium* complex mai ales la adulți (40, 41). Este posibil ca infecții cu *M.abscessus* să fi fost anterior descrise ca determinate de *M.fortuitum* complex sau *M.chelonae* din cauza dificultăților de identificare sau

schimbărilor taxonomice.

Micobacteriile atipice, prezente intermitent şi în număr mic în spută, sunt considerate de contaminare sau colonizante, fără indicaţii de tratament antibacterian.

Alte bacterii izolate de la pacienţi cu FC. Bacterii normal prezente în cavitatea bucală şi căile aeriene superioare pot fi puse în evidenţă în număr semnificativ în probe de spută şi lavaj bronho-alveolar. Dintre acestea, grupul *Streptococcus milleri* (*S. constellatus, S. intermedius, S. anginosus*), izolat pe mediu selectiv McKay, a fost asociat cu pusee de acutizări respiratorii. Administrarea de antibiotice, lipsite de activitate pentru patogenii recunoscuţi, a determinat ameliorarea manifestărilor clinice (42, 43).

În FC, tensiunea scăzută de oxigen în secreţiile căilor respiratorii poate oferi condiţii locale favorabile pentru dezvoltarea bacteriilor anaerobe: *Prevotella, Bacteroides, Veillonella, Propionibacterium, Peptostreptococcus, Actinomyces*. Prin determinări cantitative, realizate pe probe purulente de spută, au fost izolate > 10^5 UFC/ml bacterii anaerobe. Lichefierea acestor produse prin sonicare şi izolarea în număr important face improbabilă prezenţa din flora oro-faringiană; în plus, a fost demonstrată persistenţa acestora prin izolarea din probe repetate de la acelaşi pacient (44). În acest context, este luată în discuţie influenţa bacteriilor anaerobe în evoluţia clinică a bolii; ca şi în alte infecţii cronice mixte (sinuzite, abcese pulmonare), este posibil ca unele dintre acestea să interacţioneze cu speciile recunoscut patogene, contribuind la modularea virulenţei prin sinergism microbian.

Alte specii (*Serratia marcescens, Enterobacter cloacae, Klebsiella pneumoniae* şi alte enterobacteriacee, *Acinetobacter* spp, *Comamonas* spp, *Moraxella* spp, *Corynebacterium* spp etc) pot coloniza tranzitoriu TRI sau sunt considerate contaminanţi (35).

***Aspergillus* spp şi alţi fungi.** Diferite specii *Aspergillus* ubicvitare în natură, în special *A. fumigatus*, sunt izolate din sputa pacienţilor cu FC cu o frecvenţă care variază în limite largi. La majoritatea cazurilor prezenţa este tranzitorie, fără relevanţă clinică (11). Tratamentul intensiv cu antibiotice pentru infecţia cu *P. aeruginosa* favorizează această colonizare, care atunci când devine persistentă poate afecta funcţia respiratorie; administrarea de antifungice poate ameliora manifestările clinice (45). Rar sunt posibile infecţii sistemice. La copii peste vârsta de 4 ani şi la adulţi colonizaţi cronic este descrisă o entitate clinico-radiologică, aspergiloza bronho-pulmonară alergică, care beneficiază de tratament cu steroizi (46).

Scedosporium apiospermum, un alt fung filamentos saprofit cu largă distribuţie în natură a fost izolat din sputa pacienţilor cu FC; un studiu european a raportat o incidenţă de 8,6%. Importanţa sa în evoluţia bolii rămâne controversată dar a fost dovedită implicarea în infecţii invazive la cei cu transplant pulmonar (47, 48).

Specii *Candida*, în special *C. albicans*, izolate din produse provenite din TRI sunt în cele mai multe cazuri expresia unui dismicrobism consecutiv curelor repetate cu antibiotice (35, 49). Nu există dovezi certe care să susţină un rol semnificativ al speciilor *Candida* în FC.

Virusuri. La pacienţii cu FC pot evolua infecţii cu virusul respirator sincitial, virusurile gripale, paragripale, adenovirusuri şi mai recent metapneumovirus, fără ca aceştia să fie mai receptivi comparativ cu populaţia generală. Manifestările clinice sunt însă mai severe prin afectarea funcţiei de

clearance bacterian a aparatului mucociliar deja deteriorată, fiind admis un sinergism între flora bacteriană din TRI şi virusurile respiratorii (2, 4, 50). Virusul respirator sincițial a fost cel mai frecvent identificat, urmat de virusurile gripale A şi B. Această categorie de pacienți, indiferent de vârstă, au indicație de terapie şi profilaxie specifică antigripală.

CONCLUZII

Datele actuale din literatură susțin patogenitatea certă în FC a *S.aureus*, *P. aeruginosa* şi *B. cepacia*, ultimele două fiind considerate "bacterii preterminale". Microorganisme cu rol secundar, *H. influenzae*, *S.maltophilia*, *A. xylosoxidans*, micobacterii atipice, *A .fumigatus* şi virusurile respiratorii, a căror semnificație clinică nu a fost încă clarificată, necesită studii suplimentare.

PPARs: PHYSIOLOGICAL FUNCTIONS AND PHARMACOLOGICAL ROLES OF AGONISTS IN HUMAN DISEASES. Note II (Abstract) Increasing attention paid to the main family of peroxisome proliferator activated receptors - PPARs is generated, on one hand by the multiple functions of its members in numerous metabolically active tissues, and on the other hand by the therapeutic benefits expresed by some specific ligands that are used in certain metabolic diseases treatment plan. PPARα stimulates the β-oxidative degradation of fatty acids and controls plasma lipid transport through the mediated action upon the triglycerides and fatty acids metabolism and by modulation of biosynthesis and catabolism of bile acids in the liver. PPARγ promotes adipocytes differentiation and fat storage. PPARβ/δ is involved in control and management of adipogenesis. While PPARα mediates the hypolipemiant actions of fibrates, PPARγ is the receptor for thiazolidinediones (glitazones) reccomended in type 2 diabetes treatment; by binding to PPARγ, glitazones modulates transcription of genes involved in lipid and carbohydrate metabolism. **Key words:** PEROXISOME PROLIFERATOR-ACTIVATED RECEPTORS, AGONISTS, FIBRATES, THIAZOLIDINEDIONE, DIABETES MELLITUS, LIPIDS METABOLISM.

PPARs (peroxisome proliferators-activated receptors) reprezentați de un trio de receptori nucleari (PPAR-α, -γ, -β/δ) acționează ca factori de transcripție, activați de ligand. Fiecare din aceste izotipuri formează obligatoriu heterodimeri cu partenerul specific, receptorul acid 9-cis-retinoic (RXR). Heterodimerii PPARs: RXR (factori de transcripție funcționali) reglează exprimarea genelor țintă prin legarea la o secvență din ADN cunoscută ca PPRE (peroxisome preliferator response elements) amplasată în domeniile reglatoare ale genelor. După legarea agoniştilor, conformația PPARs se modifică astfel încât eliberează corepresorii permițând recrutarea cu afinitate mare a coactivatorilor care remodelează cromatina şi comunică astfel cu maşinăria transcripțională celulară ce va induce inițierea transcripției (1).

PPARs modulează transcripția genei prin două mecanisme: **a**. transactivare ADN-dependentă care implică legarea la PPRE a genelor țintă şi heterodimerizarea cu RXR şi **b**. mecanismul transrepresiei, o cale ADN-independentă, realizată prin interferența cu alți factori de transcripție ce pot explica, spre exemplu, acțiunea antiin-

flamatoare a PPAR-γ. În ultima decadă s-a acordat o deosebită atenţie acestor factori datorită implicării lor în reglarea diferitor gene cu funcţii fiziologice variate şi efecte farmacologice distincte ale agoniştilor (2).

PPAR-α, clonat în 1990, identificat şi la om, se exprimă preponderent în ţesuturi active metabolic, care cer energie, precum ficat, muşchi scheletic, intestin, cortex renal (3) şi celule cu leziuni aterosclerotice (celule endoteliale, celulele muşchiului neted, monocite/ macrofage)(1).

Mecanism de acţiune. PPAR-α activat după legarea ligandului sau după fosforilare, induce modificări conformaţionale ale receptorului care permit recrutarea de activatori şi facilitarea transcripţiei genei ţintă. Descoperirea liganzilor specifici PPARs şi identificarea multiplelor nivele de control a acestor factori a permis o mai bună înţelegere a mecanismului molecular de activare ligand-dependentă şi a rolului lor de ţinte moleculare pentru droguri utile în tratamentul bolilor metabolice umane.

Liganzii PPARα, sunt compuşi naturali sau sintetici. Liganzii naturali sunt reprezentaţi de: **a**. acizi graşi (AG) – liganzi primari care activează genele implicate în consumul, transportul intracelular, catabolismul oxidativ al AG şi **b**. eicosanoizi derivaţi din acid arahidonic pe calea lipoxigenazei sau cicloxigenazei (4). Liganzii sintetici sunt activatori farmacologici folosiţi în tratamentul bolilor metabolice precum dislipidemia (5). Legarea agonistului induce o conformaţie activată a receptorului care determină disocierea proteinelor corepresor şi permite recrutarea diferenţiată a coactivatorilor (6) care vor declanşa un răspuns biologic specific.

Agoniştii PPARα precum derivaţii acidului fibric (fibraţii): clofibrat, gemfibrozil, fenofibrat, bezafibrat, ciprofibrat sunt folosiţi în virtutea beneficiului lor terapeutic, pentru tratamentul hiperlipidemiei.

PPAR-α şi metabolismul AG, triglicеridelor (TG) şi a fracţiei LDL (low density lipoprotein). PPARα este recunoscut ca ţintă primară a clasei de droguri hipolipidemiante – a fibraţilor.

Cea mai bine caracterizată acţiune a agoniştilor PPARα priveşte metabolismul lipidelor şi lipoproteinelor la nivel hepatic şi extrahepatic. Aproape fiecare faţetă a metabolismului acizilor graşi este sub controlul transcripţional al PPARα (transport, sinteză, depozitare, mobilizare, activare, β-oxidare) (6) acţionând ca un senzor molecular al AG endogeni şi al derivaţilor lor (3), precum şi a proteinelor esenţiale implicate în metabolismul lor (7). Efectele benefice ale fibraţilor se datorează în parte creşterii exprimării genelor implicate în β-oxidarea AG, catabolismului crescut al particulelor bogate în TG şi producerii reduse de VLDL (very low density lipoprotein) (8) care, indirect scad sdLDL (small dense LDL), cresc formarea particulelor HDL şi dirijează excesul de colesterol spre excreţie hepatică în bilă.

PPARα activat de fibraţi creşte activitatea LPL (lipoprotein lipazei) responsabilă de activitatea lipolitică în ficat, muşchi (9) şi macrofage (10). Acest efect promovează lipoliza şi catabolismul lipoproteinelor bogate în TG (VLDL şi LDL), diminuându-le nivelul plasmatic.

În ficat, PPARα reglează exprimarea enzimelor căii de producere a corpilor cetonici şi ai gluconeogenezei (11).

Lipsa alimentaţiei este compensată prin lipoliză din ţesutul adipos care eliberează acizi graşi disponibili pentru oxidare în ţesuturile periferice şi conversia la corpi cetonici în ficat (11) a căror sinteză este stimulată la diabetici de PPARα.

PPARα reglează metabolismul glicerolului hepatic prin promovarea gluconeogenezei din glicerolul produs în ţesutul adipos în cursul lipolizei şi importat în ficat (12).

Fibraţii, activatori ai PPARα, reduc exprimarea apolipoproteinei (apo) C-III care inhibă atât activitatea LPL de a hidroliza TG cât şi consumul de lipoproteine remanente bogate în TG.

În hepatocitele umane, exprimarea apo A-V activator al lipolizei este reglată pozitiv de agoniştii PPARα. Administrarea agoniştilor PPARα cresc circulaţia apolipoproteinei A-V din ser şi rapotul apo A-V/apo C-III (13).

PPAR-α şi fracţia HDL.

- Fibraţii cresc transcripţia apolipoproteinelor majore ale HDL, apo AI şi apo AII (14) şi în consecinţă creşterea concentraţiei HDL. La persoanele tratate cu fibraţi scade incidenţa evenimentelor cardiovasculare, iar la pacienţii cu diabet tip 2 caracterizaţi prin hiper-trigliceridemie moderată şi concentraţie mică de colesterol HDL, fibraţii scad incidenţa infarctului de miocard.
- Activatorii PPARα cresc transportul invers de colesterol (RTC-reverse cholesterol transport) prin accelerarea efluxului de colesterol din celulele periferice şi creşterea consumului lui de către ficat de unde colesterolul este eliminat prin bilă, fie direct, fie după metabolizare la acizi biliari. PPARα influenţează calea RTC prin reglarea efluxului de colesterol din macrofage (3).

Efectele pleiotrope ale fibraţilor. În plus de principalele efecte benefice în homeostazia lipidică induse de fibraţi, diferite studii efectuate *in vitro* şi *in vivo* au demonstrat numeroase efecte pleiotrope suplimentare. PPARα, activaţi de fibraţi, se exprimă în sistemul cardiovascular, în celulele endoteliale, celulele muşchiului neted vascular, monocite, macrofage (1).

- Principala acţiune a PPARα la nivelul cordului este aprovizionarea cu energie prin activarea genelor care reglează consumul şi oxidarea mitocondrială a AG (15).
- Fenofibratul, (denumit iniţial procetofen), asigură protecţia miocardului, prevenind instalarea şi evoluţia hipertensiunii, hipertrofia cardiacă, insuficienţa cardiacă, miocardita, disfuncţia vasculară endotelială (16, 17).
- Fenofibratul, ca agonist al PPARα îmbunătăţeşte funcţia endotelială prin exprimarea crescută şi eliberarea de NO (18).
- PPARα reglează exprimarea proteinelor cheie implicate în toate stadiile aterogenezei incluzând inflamaţia vasculară, instabilitatea plăcii şi tromboza (19). Activarea PPARα poate avea efecte antiaterogene directe asupra diferitor tipuri de celule din peretele vascular, de ex. scăderea exprimării moleculelor de adeziune, a factorului tisular, Il-6 (interleukinei-6), endotelinei-1.
- Interacţiunea cu diferiţi factori de transcripţie (VCAM-vascular cell adhesion molecule, ICAM-intercellular adhesion molecule, PECAM-platelet endothelial cell adhesion molecule, molecule de adeziune plachetare şi endoteliale, CRP-C-reactive protein ş.a.) PPARα inhibă gene proinflamatoare (16). De asemeni, activarea PPARα scade inflamaţia celulară prin inhibarea căilor de semnalizare precum AP-1 (activator protein-1), factorul nuclear kappa B, care împreună scad stresul oxidativ vascular şi sistemic.

PPARγ factor de transcripţie ce acţionează ca receptor pentru tiazolidindione (TZD)(glitazone) creşte transcripţia genelor sensibile la insulină (20), şi este cel mai bine caracterizat, în parte datorită potenţia-

lului terapeutic pentru tratamentul diabetului (21) şi al consecinţelor legate de sindromul metabolic (22). După descoperire, glitazonele au devenit foarte populare şi frecvent prescrise datorită sensibilităţii crescute la insulină fără să determine hipoglicemie şi implicării şi în alte condiţii patologice umane (23).

Mecanism de acţiune. Glitazonele ca agonişti selectivi ai PPARγ, acţionează prin legarea la PPARγ. Când este activat de ligand, PPARγ formează heterodimerul PPARγ:RXR care se leagă la ADN şi reglează transcripţia genetică şi translaţia unei mari varietăţi de proteine implicate în diferenţierea celulară, metabolismul glucidic şi lipidic.

Liganzii PPARγ. PPARγ leagă şi este activat de compuşi (liganzi) care apar în mod natural precum 15-deoxi-Δ12,14 – prostaglandin J2 (15-PGJ2), diferite eicosanoide şi compuşi sintetici precum TZD (24). Faptul că liganzii se deosebesc prin capacittea lor de a interacţiona cu coactivatori explică diferitele răspunsuri biologice descrise.

Primii agonişti sintetici identificaţi pentru PPARγ au fost TZD care ameliorează rezistenţa la insulină (diabet zaharat non-insulino-dependent, NIDDM). TZD utilizate în tratamentul diabetului zaharat de tip 2 includ: ciglitazone, pioglitazone (Actos), troglitazone (Rezulin), rosiglitazone (Avandia), rivoglitazone, balaglitazone compuşi cu profil de securitate diferit, astfel că cele mai utilizate clinic sunt pioglitazone şi rosiglitazone.

Efectele PPARγ-dependente ale TZD. Funcţiile celulare ale PPARγ se exprimă abundent în ţesutul adipos şi celulele epiteliale ale colonului şi multe alte ţesuturi precum muşchi scheletic, ficat, inimă, intestin, monocite/macrofage, pneumocite, miocite (1).

Defectul de început în dezvoltarea diabetului de tip 2 este rezistenţa la insulină-factor de risc major, caracterizat prin scăderea transportului glucozei şi a metabolismului ei în muşchiul scheletic (25).

Prin activarea PPARγ, TZD cresc exprimarea proteinelor implicate atât în metabolismul glucidic, cât şi lipidic.

▪ TZD contribuie la scăderea rezistenţei la insulină, atenuarea hiperinsulinismului, îmbunătăţirea sensibilităţii la insulină dovedită în ţesutul adipos, ficat, muşchi scheletic. Pot reface sensibilitatea la insulină prin scăderea citokinei TNF-α (26) şi creşterea exprimării adiponectinei (27).

▪ Activarea PPARγ creşte exprimarea şi translocarea transportorilor 1 şi 4 de glucoză de la suprafaţa celulei, crescând consumul de glucoză în ficat şi muşchiul scheletic.

▪ La pacienţi cu control glicemic neadecvat, TZD reduc nivelul hemoglobinei glicate (glicozilate) (Hb A1c) şi al glucozei plasmatice în condiţie de post.

În plus, de eficacitatea în controlul glicemiei prin sensibilitatea la insulină, TZD au **efecte pleiotrope** asupra metabolismului lipidelor, presiunii sanguine, funcţiei endoteliale, celulelor muşchiului neted vascular, macrofage, inflamaţiei, aterosclerozei, plăcii aterosclerotice, coagulării, albuminuriei ş.a. în funcţia imună a monocitelor/macrofagelor (28, 29, 30, 31, 32).

▪ Se consideră că TZD şi alţi agonişti PPARγ îşi exercită efectele pleiotrope direct în ţesutul adipos, care în final duc la sensibilizarea la insulină în muşchiul scheletic şi ficat (33).

▪ În ţesutul adipos, activarea PPARγ duce la inducţia multor gene implicate în eliberarea şi consumul de acizi graşi având

drept consecinţă scăderea nivelului de acizi graşi liberi şi trigliceride şi în final la reducerea depozitelor de grăsimi în muşchi, ficat şi viscere .

▪ TZD cresc secreţia de adiponectină şi scad producerea de rezistină şi a factorului de necroză tumoral (TNF-α) (34), în contextul inflamaţiei acute. La persoanele obeze s-a observat producere crescută de TNF-α în ţesutul adipos implicat ca factor cauzativ în obezitatea asociată cu rezistenţa la insulină şi patogeneza diabetului de tip 2. De asemenea, TZD cresc cHDL, cresc mărimea/scad densitatea LDL. Alte efecte PPARγ-dependente includ: inducţia diferenţierii adipocitare, inhibarea angiogenezei indusă de factorul de creştere endotelial vascular (VEGF), modificarea nivelului leptinei.

▪ În contextul rezistenţei la insulină şi a diabetului de tip 2, dislipidemia se caracterizează prin modificarea lipidelor plasmatice, în principal prin oxidare şi glicare. Aceste lipide modificate sunt implicate în iniţierea aterogenezei. În virtutea efectelor favorabile asupra profilului lipidic (35), pioglitazona poate avea efecte pozitive asupra sistemului cardiovascular (36) şi a complicaţiilor cardiovasculare. TZD modifică favorabil distribuţia grăsimilor şi îmbunătăţesc factorii de risc cardiovasculari precum presiunea sanguină, markeri inflamatori, acidul uric, întârzie evoluţia aterosclerozei, atenuează nivelul circulator al mediatorilor proinflamatori (37). De asemenea, TZD reduc nivelul plasmatic al chemokinelor, proteinei-1 monocitare chemotactice (MCP-1), proteinei antifibrinolitice, inhibitor-1 al activatorului plasminogenului, moleculei de adeziune a celulei endoteliale, C-selectinei, ICAM-1 (38) şi au efect antioxidant (39).

▪ Deşi TZD utilizate terapeutic sunt considerate ca droguri fără probleme, s-au observat unele efecte comune colaterale care includ: câştig în greutate (40), retenţie de apă care reprezintă un risc semnificativ pentru pacienţii cu funcţie ventriculară scăzută. Retenţia de sodiu şi expansiunea volumului plasmatic au fost legate de stimularea PPARγ în epiteliul ductului colector renal.

▪ De asemenea, glitazonele scad formarea osului şi a masei osoase şi cresc frecvenţa fracturilor cel puţin la femei (41). Un risc crescut pentru boala coronariană s-a observat cu rosiglitazonă (41), în timp ce s-a dovedit că rosiglitazona scade evoluţia aterosclerozei (42).

Această listă este departe de a fi completă, dar poate oferi o idee asupra multiplelor gene reglate după stimularea PPARγ.

Pentru că mulţi pacienţi cu rezistenţă la insulină manifestă dislipidemie, a fost practic judicios să se producă agonişti duali PPARα/γ în tratarea acestor bolnavi. Aceşti agonişti, denumiţi glitazari, combină efectul de sensibilizare la insulină ale activării PPARγ, cu efectul de scădere a lipidelor, ale agoniştilor α care scad trigliceridele, cresc nivelul HDL şi sensibilitatea la insulină şi reducerea riscului cardio-vascular. De asemenea, în tratamentul diabetului zaharat tip 2 se pot administra pioglitazonă în combinaţie cu metformin, sulfoniluree, exenatide, insulină (43) ş.a. Terapia cu aleglitazar (agonist dual PPARα/γ) reduce hiperglicemia şi modifică în mod favorabil nivelul c-HDL şi al trigliceridelor. În continuare, acest glitazar se studiază clinic dacă reduce riscul major de infarct miocardic, stroke, moarte, la pacienţi cu diabet şi boli arteriale.

Terapia combinată poate fi o importantă paradigmă pentru tratamentul şi încetinirea aterosclerozei, a bolilor coronariene, a

dezordinilor de co-morbiditate metabolică caracterizate prin disfuncţie endotelială şi rezistenţă la insulină (44).

PPAR β/δ a fost clonat în 1990.

Distribuţia. Exprimarea PPARβ/δ este esenţială în toate tipurile de celule şi ţesuturi. Nivele mari a acestei izoforme se găsesc în intestin subţire, colon, inimă, ţesut adipos, creier (1).

Mecanismul de acţiune impune, ca şi în cazul celorlalte izotipuri, formarea de heterodimeri cu RXR (PPAR:RXR), dar se deosebeşte de acestea prin selectivitate şi sensibilitate la liganzi care la rândul lor diferă prin capacitatea de a interacţiona cu coactivatori, ceea ce explică diferite răspunsuri biologice. Liganzii PPARβ/δ sunt agenţi sintetici eficace şi selectivi precum acizii fenoxiacetici 4-tiosubstituiţi (45).

Efectele PPARβ/δ. Deşi sunt disponibile informaţii limitate asupra funcţiilor biologice ale acestui receptor datorită lipsei unui antagonist utilizat curent în clinică pot contribui la mai puţina cunoaştere a acţiunilor lui. Exprimarea PPARβ/δ în aproape toate tipurile de celule şi ţesuturi sugerează rolul lor potenţial fundamental în biologia celulară şi posibelele efecte ale agoniştilor.

◊ Studii recente au arătat implicarea lui în reglarea metabolismului glucidic, în transportul şi oxidarea acizilor graşi (46, 47), implicarea în diferenţierea epidermică, maturarea şi vindecarea rănilor pielii (48).

◊ Activarea PPAR β/δ are efecte benefice directe asupra homeostaziei vasculare prin protejarea celulelor endoteliale de inflamaţie şi apoptoză, scăderea, scăderea inflamaţiei şi promovarea angiogenezei.

Aceste efecte conferă un potenţial promiţător agoniştilor PPAR β/δ pentru tratamentul diferitor afecţiuni.

METALLO-BETA-LACTAMASE-MEDIATED RESISTANCE AMONG CARBAPENEM-RESISTANT *PSEUDOMONAS AERUGINOSA* CLINICAL ISOLATES (Abstract): **The aim** of our study was to evaluate the antimicrobial susceptibility profile and the presence of metallo-beta-lactamases (MBLs) among carbapenem-resistant *Pseudomonas aeruginosa* clinical isolates. **Material and methods.** A total of 84 *P. aeruginosa* clinical isolates collected between January 2007- February 2011 from four university hospitals in Iasi (North-East region of Romania) were randomly selected. Antimicrobial susceptibility testing was performed according to CLSI 2010 (*Clinical and Laboratory Standards Institute*) guidelines. The isolates were tested for MBLs using EPI (EDTA-phenanthroline-imipenem) phenotypic test and polymerase chain reaction (PCR) for bla_{VIM} and bla_{IMP}. **Results.** Fifty-eight carbapenem resistant strains were identified, from which 24 (41,3%) were positive for VIM - type MBLs. No IMP - type MBL was detected. All MBL-producing isolates displayed a MDR (multidrug resistant) phenotype, two of them were XDR (extensively drug-resistant). Colistin remained the most effective antibiotic. **Conclusions**. The high proportion of MBL producing *P. aeruginosa* clinical isolates urges the need for a better use of antibiotics and for efficient infection control measures to prevent dissemination of MBL producers. This is the first report of VIM-like enzymes in *P. aeruginosa* isolates from the Iasi area. **Key words**: *PSEUDOMONAS AERUGINOSA*, CARBAPENEM-RESISTANCE, METALLO-BETA-LACTAMASES

Pseudomonas aeruginosa este un frecvent patogen nosocomial, implicat într-o gamă largă de infecții şi care, prin rezistența intrinsecă la numeroase antibiotice şi prin acumularea de noi mecanisme de rezistență, pune mari probleme de tratament şi de control al infecției.

Rezistența la imipenem rezultă adesea prin pierderea porinei *OprD* sau prin creşterea expresiei pompelor de eflux. Carbapenemazele (incluzând serin carbapenemazele de clasă A şi D şi metalo-β-lactamazele - MBL) sunt enzime emergente de mare interes, deoarece conferă rezistență la carbapeneme, antibiotice valoroase împotriva bacililor Gram-negativi multirezistenți. Metalo-beta-lactamazele (MBL) transferabile aparțin clasei moleculare B, cu zinc în centrul activ, nu sunt influențate de inhibitorii terapeutici de β–lactamaze şi conferă rezistență la toate β-lactaminele, exceptând aztreonamul. Genele ce codifică

MBL se găsesc pe elemente genetice mobile, împreună cu alți determinanți de rezistență, astfel încât prezența lor constuie un marker pentru multidrog rezistență (1). Prima MBL transferabilă, IMP-1 a fost descoperită în Japonia spre sfârşitul anilor 80' la tulpini de *Pseudomonas aeruginosa* multirezistente la antibiotice. În ultimii 10 ani 9 tipuri de MBL au fost descrise, pe baza secvenței de aminoacizi, ulterior acestea diseminând rapid printre tulpini de *Pseudomonas* spp., *Acinetobacter* spp., *Enterobacteriaceae*. Cele mai frecvente şi mai răspândite la nivel mondial sunt enzimele IMP (*imipenemase*) şi VIM (*Veronese imipenemase*); SPM (*Sao Paulo metallo-β-lactamase*), endemică în America de Sud, a fost importată recent în Elveția, GIM (*German imipenemase)*, SIM (*Seul imipenemase)* şi AIM (*Australian imipenemase*) au fost semnalate în Germania, Coreea de Sud, respectiv Australia (2). Enzimele KHM (*Kyorin Hospital metallo-β-lactamase*) şi DIM (*Dutch imipenemase*) au fost identificate doar la tulpini de *Citrobacter freundii* în Japonia, respectiv *Pseudomonas stutzeri* în Olanda. Deşi depistată inițial la tulpini de *Klebsiella pneumoniae* şi *Escherichia coli* din India, MBL NDM-1 s-a transmis la *P. aeruginosa*, primul izolat fiind raportat în Serbia (3).

Prevalența MBL la tulpini de *P. aeruginosa* variază semnificativ între țări, între oraşe şi chiar între centrele medicale: 1,3% în Italia la nivel național, respectiv 9,2% la Napoli; 0,1% în Spania, 7,5 - 44% în Brazilia, 1,9% în Japonia (1).

Studiile noastre au identificat prezența VIM-2 şi IMP-13 la două izolate de *P. aeruginosa* din Galați (Pa16GL), respectiv Iaşi (Pa247), tulpina producătoare de IMP-13 din Iaşi fiind înrudită clonal cu cea responsabilă de o izbucnire epidemică în sudul Italiei (4).

În acest studiu ne-am propus investigarea profilului de sensibilitate la antibiotice şi determinarea frecvenței MBL la tulpini de *P. aeruginosa* rezistente la imipenem, izolate în 4 spitale universitare din Iaşi.

MATERIAL ŞI METODE

Tulpinile bacteriene. Lotul a inclus 84 tulpini de *Pseudomonas aeruginosa* izolate în 4 spitale universitare din Iaşi: Spitalul Clinic Universitar de Boli Infecțioase (58 tulpini), Spitalul Clinic Universitar Județean de Urgențe "Sf. Spiridon" (12 tulpini), Centrul de Cardiologie Iaşi (8 tulpini), Spitalul Clinic Universitar "Dr. C. I. Parhon" (6 tulpini), în perioada ianuarie 2007 - februarie 2011. Majoritatea izolatelor au provenit din puroi şi urină (41,8%, respectiv 40,3%), restul din spută, hemocultură, aspirat traheal, lichid cefalorahidian, exsudat faringian.

Testarea sensibilității la antibiotice am efectuat-o conform standardelor CLSI (*Clinical and Laboratory Standards Institute*) 2010 (5). Am testat prin metoda difuzimetrică sensibilitatea la piperacilină-tazobactam (TZP), ceftazidim (CAZ), cefepim (FEP), aztreonam (ATM), imipenem (IPM), ciprofloxacin (CIP), tobramicină (TOB), gentamicină (GM), amikacină (AK) şi colistin (COL) (*Oxoid Ltd., Basingstoke*, Hampshire, Marea Britanie). Concentrațiile minime inhibitorii (CMI) la IPM şi CAZ le-am determinat prin metoda microdiluțiilor în bulion. Procentele de rezistență la CAZ şi IPM au fost calculate pe baza punctelor de ruptură recomandate de CLSI 2010 pentru categoria total sensibil (izolatele intermediare le-am considerat rezistente).

Detectarea fenotipică a producerii de metalo-β-lactamaze am efectuat-o prin testul fenotipic EPI (*EDTA-phenanthroline-imipenem*), care are la bază susceptibilitatea MBL la inhibiția prin chelatori de metale, amestecul de EDTA şi o-fenan-

trolină (6). Acest test constă în determinarea CMI la imipenem în absența şi în prezența amestecului chelator. O scădere de ≥4 ori a valorii CMI pentru imipenem în prezența chelatorilor este considerată ca sugestivă pentru producerea de MBL.

Analiza prin moleculară prin *polymerase chain reaction* (PCR).

Pentru detectarea genelor de tip bla_{VIM} şi bla_{IMP} am efectuat un multiplex PCR cu următorii primeri (*Eurogentec*, Liège, Belgia):

IMP-DIA-FWD (5'-GGAATAGAGTGGCTTAATTCT-3'),
IMP-DIA-REV (5'-GTGATGCGTCYCCAAYTTCACT-3'),
VIM-DIA-FWD (5'-CAGATTGCCGATGGTGTTTGG-3'),
VIM-DIA-REV (5'-AGGTGGGCCATTCAGCCAGA-3') (7),

care generează ampliconi de 361 bp pentru bla_{IMP} şi de 523 bp pentru bla_{VIM}. Reacția a cuprins: ADN matriță 2 µl (vezi mai jos), 50 pmol din fiecare primer, dezoxinucleozidtrifosfați 200 µM, 1 U de polimerază Taq (*Fermentas International Inc.*, Canada), $MgCl_2$ 1,5 mM şi soluție tampon asigurat de producător până la un volum final de 50 µl. Matrița ADN am obținut-o astfel: din cultura proaspătă pe agar Mueller-Hinton am preparat o suspensie densă în 500 µl apă distilată, pe care am fiert-o 15 min. Resturile celulare distruse le-am îndepărtat prin centrifugare (5 min, 13000 rpm), iar supernatantul l-am folosit ca sursă de ADN pentru amplificare, în termocilor *Corbett CG1-96* (*QIAGEN*). Parametrii reacției au fost: 3 min la 94°C, 30 cicluri de 1 min la 94°C, 1 min la 52°C, 1 min la 72°C, şi o extensie finală de 10 min la 72°C. Produşii de amplificare au fost separați prin electroforeză în gel de agaroză 1,5%, cu scală de 100 bp (*Promega*, SUA) la putere de 100 V, 1,5 ore, folosind un aparat *Scie-Plas HU13W*, Marea Britanie.

Controlul de calitate l-am asigurat utilizând tulpina de *Pseudomonas aeruginosa* ATCC 27853, iar tulpinile de *P. aeruginosa* Pa16GL şi Pa247 au reprezentat martorii pozitivi.

REZULTATE ŞI DISCUȚII

Prin antibiograma difuzimetrică, din 84 de tulpini *P. aeruginosa* incluse în studiu 54 au fost rezistente la IPM, 55 la CAZ, 47 la FEP, 57 la CIP, 50 la TZP, 11 la ATM, 55 la GM, 57 la TOB, 53 la AK, niciuna la COL.

Analiza comparativă a rezultatelor antibiogramei difuzimetrice şi ale antibiogramei prin metoda microdiluțiilor a reîncadrat în valori de sensibilitate tulpinile testate astfel: 2 tulpini rezistente şi 5 sensibile la IPM au fost încadrate ca intermediare (CMI=8 mg/L); față de CAZ, 3 tulpini rezistente au fost clasificate ca intermediare (CMI=16 mg/L), una rezistentă ca sensibilă şi 2 sensibile ca rezistente.

Valorile CMI la CAZ şi IPM pentru tulpinile investigate s-au încadrat între 1 - ≥ 128 mg/L (fig.1), cu predominanța izolatelor cu rezistență înaltă la cele două antibiotice (CMI ≥ 128 mg/L).

Pentru urmărirea modificărilor în timp ale rezistenței bacteriene, standardele internaționale recomandă prezentarea datelor de supraveghere a rezistenței ca valori CMI_{50} sau CMI_{90} (8). Tulpinile de *P. aeruginosa* studiate s-au remarcat prin valori ridicate ale CMI_{50} şi CMI_{90} atât pentru IPM (32 mg/L, respectiv >128 mg/L), cât şi pentru CAZ (32 mg/L, respectiv 128 mg/L) şi procente crescute de rezistență la IPM şi CAZ (69,1%, respectiv 60,8%). Conform definițiilor propuse în 2011 (9), 55 de tulpini (65,47%) au prezentat fenotip MDR (*multidrug resistant*), fiind rezistente la cel

puțin un antibiotic din cel puțin trei clase diferite: peniciline anti-*Pseudomonas* şi un inhibitor de β-lactamază, cefalosporine anti-*Pseudomonas*, carbapeneme, aminoglicozide, fluorochinolone, polimixine; 9 tulpini (10,71%) au fost XDR (*extensively drug-resistant*), deoarece au prezentat rezistență la cel puțin un antibiotic din cel puțin şase din categoriile de antibiotice menționate. Nu am depistat nicio tulpină PDR (*pandrug-resistant*), definită ca rezistentă la toate categoriile de antibiotice.

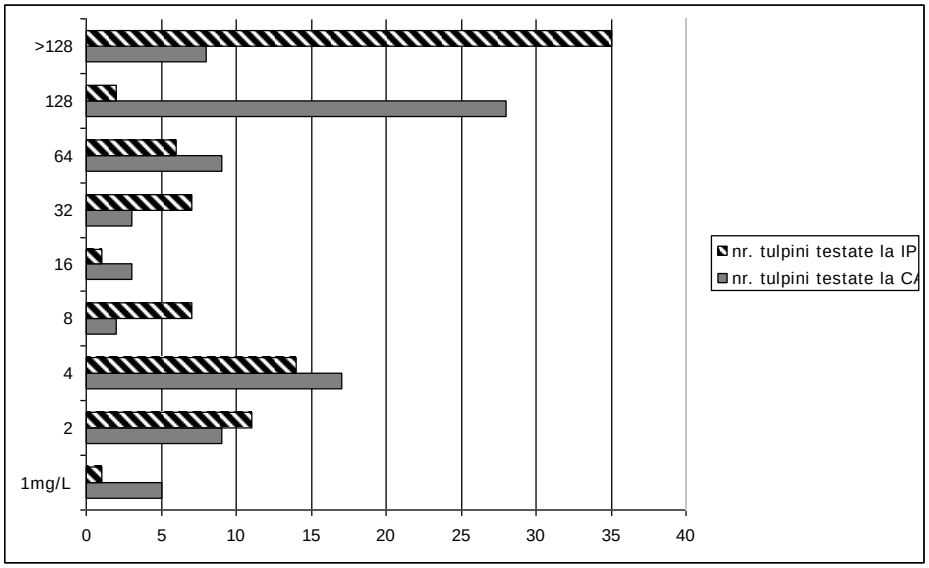

Fig. 1. Distribuția CMI (mg/L) la ceftazidim (CAZ) şi imipenem (IPM) pentru cele 84 tulpini de *P. aeruginosa* studiate.

Din totalul de 84 tulpini de *P. aeruginosa*, pentru 24 (28,5%) am obținut rezultate pozitive la testul fenotipic EPI, reprezentate de o scădere de ≥4 ori a CMI pentru imipenem în prezența chelatorilor.

Prin multiplex PCR am detectat gene codante pentru MBL tip VIM la 24 izolate din lotul investigat (fig. 2). Nu am identificat în acest studiu nici o genă bla_{IMP} şi nici gene pentru MBL, la tulpinile sensibile la imipenem.

Majoritatea tulpinilor producătoare de MBL au provenit din urină (15 tulpini), restul fiind izolate din puroi (5), aspirat traheal (2), spută (1) şi hemocultură (1).

Tulpinile de *P. aeruginosa* producătoare de MBL au prezentat fenotipul MDR, două dintre ele fiind XDR. Ele au fost rezistente la ceftazidim (CMI între 32-128 mg/L), cefepim, imipenem (cu rezistență de nivel înalt CMI>128 mg/L), ciprofloxacin, gentamicină, tobramicină, amikacină, toate fiind sensibile la colistin. Aztreonamul s-a dovedit al doilea antibiotic, ca eficiență, doar 2 tulpini fiind rezistente, sugerând asocierea şi a altor mecanisme de rezistență la beta-lactamine.

Izolatele pozitive pentru gena bla_{VIM} au fost depistate în toate cele patru spitale: o tulpină la Centrul de Cardiologie Iaşi, 2 tulpini la Spitalul Clinic Universitar "Dr. C. I. Parhon", 5 la Spitalul Clinic Universitar Județean de Urgențe "Sf. Spiridon" şi 16 la Spitalul Clinic Universitar de Boli In-

fecțioase.

În ansamblu, proporția tulpinilor producătoare de MBL a fost de 28,5% din întregul lot şi de 41,3% din izolatele intermediare şi rezistente la imipenem. Am detectat numai MBL tip VIM, acestea fiind cel mai frecvent raporatate şi la nivel mondial (1, 2).

Prevalența rezistenței la carbapeneme mediate prin MBL la tulpini de *P. aeruginosa* variază semnificativ între țări. În Polonia, din 311 izolate, 22% au fost rezistente la carbapeneme, dintre acestea 60% produceau MBL, iar majoritatea au fost de tip VIM (10). În Brazilia MBL au fost identificate la 30,4% din 69 tulpini de *P. aeruginosa* rezistente la imipenem izolate din hemoculturi (11). Un studiu din Croația a identificat 6 tulpini producătoare de VIM-2 dintre 100 tulpini rezistente la imipenem sau meropenem (12). Din 104 tulpini rezistente la imipenem izolate în Nord-Vestul Iranului 23% produceau MBL, predominant VIM (13). În Norvegia şi Suedia între 1999 şi 2007 au fost raportate numai 4, respectiv 9 tulpini de *P. aeruginosa* producătoare de MBL (2). Un studiu recent realizat în Germania semnalează că 1,6% dintre 489 izolate de *P. aeruginosa* şi 11,7% dintre tulpinile cu sensibilitate redusă la imipenem sunt producătoare de MBL, procente similare cu cele raportate în Italia şi Coreea unde însă diversitatea MBL este mai mare (14).

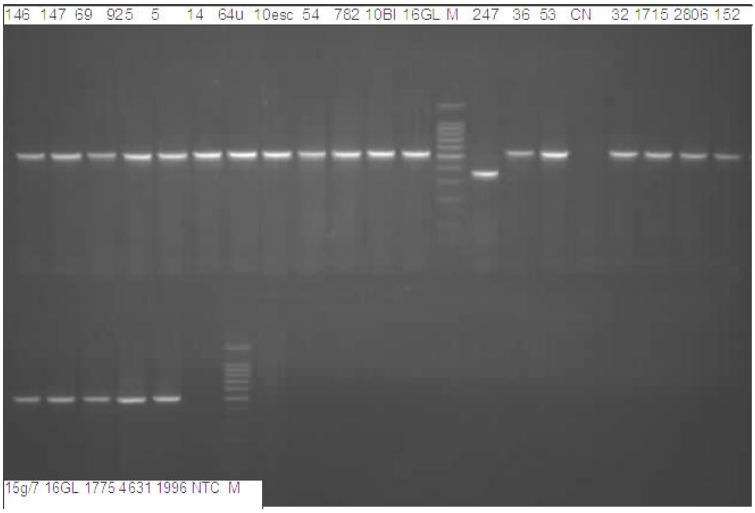

Fig. 2. Multiplex PCR pentru detectarea genelor de tip bla_{VIM} şi bla_{IMP}. M = 100 bp DNA ladder; CN= control negativ; NTC= *non template control*. 16GL= martor pozitiv pentru gena bla_{VIM}, cu fragment amplificat de 523 bp; 247= martor pozitiv pentru gena bla_{IMP}, cu fragment amplificat de 361 bp. Tulpinile testate posedă un amplicon de 523 bp, ceea ce sugerează genă de tip bla_{VIM}.

CONCLUZII

În acest studiu a fost depistată pentru prima dată gena codantă pentru MBL de tip VIM la tulpini de *P. aeruginosa* rezistente la carbapeneme izolate în spitale universitare din Iaşi.

Procentele de rezistență înregistrate la imipenem (69,1%) şi la ceftazidim (60,8%) trag un semnal de alarmă asupra utilizării corecte, restrictive a acestor antibiotice în

terapia infecțiilor produse de bacili Gram-negativi (*Enterobacteriaceae, P. aeruginosa, Acinetobacter* spp). Supravegherea în condiții standardizate a sensibilității la antibiotice a tulpinilor de *P. aeruginosa* este utilă pentru cunoaşterea spectrului de sensibilitate actual al bacteriilor la antibiotice, cu implicații directe în limitarea răspândirii tulpinilor multidrog rezistente.

Proporția mare a tulpinilor producătoare de MBL (28,5%) limitează opțiunile terapeutice în infecțiile cu *P. aeruginosa*, doar la colistin şi impune măsuri pentru prevenirea infecției nosocomiale şi a transferului orizontal al acestor bacterii.

Notă. Acest studiu a fost finanțat prin grantul intern nr. 17078/30.09.2010 acordat de Universitatea de Medicină şi Farmacie "Gr. T. Popa", Iaşi.

THE INFLUENCE OF STRESS FACTORS ON LIVER FUNCTION AND LIPID METABOLISM IN AN ANIMAL MODEL OF ARTERIAL HYPERTENSION (Abstract): **Aim**: to investigate the influence of some stress factors on hepatic function and lipid metabolism in an experimental-induced hypertension. **Material and methods**: The experiment was carried out on Wistar rats, treated intraperitoneally, for 4 weeks, as follows: Group 1: saline solution (0.5ml/100g weight); Group 2: saline solution + stress; Group 3: Endotelin-1; Group 4: Endotelin-1 + stress; Group 5: Endotelin-1 + cholesterol diet (0.2g/kbw/day); Group 6: Endotelin-1 + cholesterol diet + stress. Endotelin-1 0.25nmol/kbw was initially administered, followed by 0.5nmol/kbw 15 min later, 2 times/week. Stress-inducing factors were immobilization and water immersion. In the 28^{-th} day of the experiment blood pressure was measured and blood samples were taken from retro-orbitary plexus to assess glutamic oxaloacetic transaminase (GOT), glutamic pyruvic transaminase (GPT) and lactic dehydrogenase (LDH) activity, total cholesterol, low-density lipoprotein (LDL) cholesterol, high-density lipoprotein (HDL) cholesterol, triglycerides levels. **Results**: Using immobilization and water immersion as chronic stress, our study proved an increase of GOT, GTP and total and LDL cholesterol in rats with endotelin-1-induced hypertension. **Conclusions**: In this animal model of endothelin-1-induced hypertension the blood pressure increased significantly under chronic exposure to stress, reaching the highest values when associating stress and experimentally induced dyslipidemia. **Key words**: STRESS, CHOLESTEROL, BLOOD PRESSURE.

Hipertensiunea arterială (HTA) este considerată una dintre cele mai importante probleme de sănătate publică din ţările dezvoltate, ea evoluând, de multe ori, fără a fi diagnosticată, monitorizată şi tratată adecvat, deşi este extrem de uşor de depistat. Persoanele cu HTA nu prezintă mult timp nici un simptom, motiv pentru care această boală a fost supranumită "ucigaşul tăcut".

Stresul obligă organismul să fie într-un continuu proces de adaptare. Starea de stres experimentată în mod regulat, pentru perioade lungi de timp, este cea care poate produce HTA, prin accelerarea bătăilor inimii şi prin vasoconstricţia indusă de eliberarea neurohormonilor. Acest fond predispune la HTA (1). Tensiunea arterială poate creşte în condiţii de stres şi stare de tensiu-

ne, cel puţin pe moment, când persoana se confruntă cu agentul stresor, această reacţie făcând parte din răspunsul general al organismului la stres. (2,3) Deşi există o astfel de relaţie demonstrată între cele două elemente (HTA şi stres), încă nu s-a stabilit dacă diminuarea stimulilor psihologici şi a situaţiilor stresante din jur poate reduce pe termen lung şi HTA (4).

Stresul mental cronic creşte presiunea arterială, precum şi nivelul colesterolului, conducând, astfel, la HTA cronică şi dislipidemie.

Studiile efectuate au pus în evidenţă existenţa unor corelaţii între diferitele tipuri de stres, reactivitatea organismului şi modificările presionale (5,6).

Scopul studiului a constat în cercetarea influenţei unor factori de stres asupra funcţiei hepatice şi a metabolismului lipidic, pe un model de HTA indusă experimental la animale de laborator.

MATERIAL ŞI METODĂ

Pentru experiment au fost utilizate 6 loturi de câte 6 şobolani Wistar (180-200g), cu repartiţie uniformă pe sexe, proveniţi de la Institutul de Sănătate Publică din Iaşi, trataţi conform schemei:

L1 = SF = Ser fiziologic (0,5 ml/100g corp/zi);

L2 = SF+s = Ser fiziologic (0,5 ml/100g corp/zi) + stres indus de imobilizare şi imersie în apă;

L3 = ET-1 = Endotelină-1 (0,25 nmol/kg corp, i.p., iar după 15 min 0,5 nmol/kg corp, i.p., 2 administrări pe săptămână, 4 săptămâni);

L4 = ET-1+s = Endotelină-1 (0,25 nmol/kg corp, i.p., iar după 15 min 0,5 nmol/kg corp, i.p., 2 administrări pe săptămână, 4 săptămâni) + stres indus de imobilizare şi imersie în apă;

L5 = ET-1+col = Endotelină-1 (0,25 nmol/kg corp, i.p., iar după 15 min 0,5 nmol/kg corp, i.p., 2 administrări pe săptămână, 4 săptămâni) + dietă cu colesterol (0,2 g/kg corp/zi, 4 săptămâni);

L6 = ET-1+col+s = Endotelină-1 (0,25 nmol/kg corp, i.p., iar după 15 min 0,5 nmol/kg corp, i.p., 2 administrări pe săptămână, 4 săptămâni) + dietă cu colesterol (0,2 g/kg corp/zi, 4 săptămâni) + stres indus de imobilizare şi imersie în apă.

Substanţele au fost administrate conform schemei de mai sus, începând cu ora 8 dimineaţa, timp de 28 de zile. După 28 de zile de tratament au fost evaluate valorile tensiunii arteriale şi s-a recoltat sânge din plexul retroorbitar, pentru determinarea următorilor parametri: valorile transaminazei glutamic oxaloacetice (TGO), transaminazei glutamic piruvice (TGP), lactat dehidrogenazei (LDH), bilirubinei serice totale, colesterolului total, LDL-colesterolului şi HDL-colesterolului, trigliceridelor şi glicemiei. Aceşti parametri au fost determinaţi cu un analizor pentru teste biochimice VITROS 750 XRC, folosind reactivi Johnson&Johnson. Rezultatele au fost apoi prelucrate statistic folosind testul *t-Student* al programului Microsoft Office Excel.

Cercetările care au fost efectuate în cadrul studiului s-au realizat în strictă concordanţă cu normele Comisiei de Etică a Universităţii şi reglementările etice internaţionale, privind lucrul pe animale de laborator.

REZULTATE ŞI DISCUŢII

Modelul experimental realizat poate fi folosit pentru studiul rolului endotelinei în etiopatogeneza HTA indusă experimental la animale de laborator, constituind, în acelaşi timp, o alternativă mult mai puţin costisitoare, la utilizarea şobolanilor modificaţi

genetic care dezvoltă HTA. (7,8,9)

Cercetările noastre anterioare (10) au demonstrat că administrarea repetată de Endotelină-1 a determinat creşterea valorilor tensiunii arteriale la şobolanii Wistar. Aceste valori sunt semnificativ statistic crescute în condiţiile expunerii la stres comparativ cu animalele care nu au fost menţinute în aceste condiţii experimentale. Cele mai ridicate valori ale tensiunii arteriale au fost înregistrate la şobolanii Wistar cărora li s-a administrat Endotelină-1, dietă cu colesterol şi au fost expuşi unui stres cronic (fig. 1).

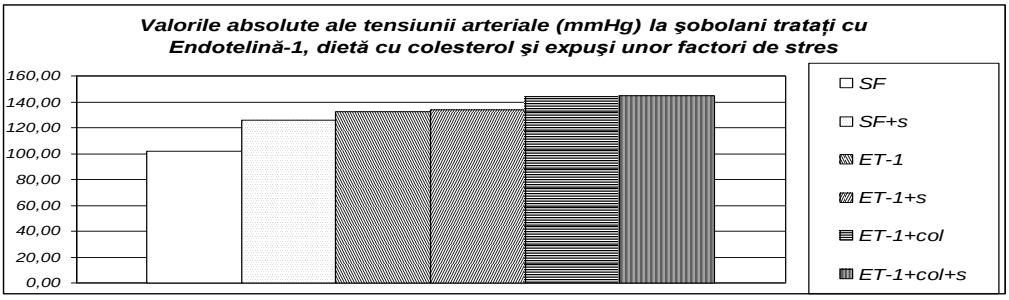

Fig. 1. Valorile absolute ale tensiunii arteriale după 28 de zile

În cursul experimentelor, s-a constatat, însă, creşterea TGO (fig. 2) şi TGP (fig. 3) la toate loturile analizate, comparativ cu lotul martor. Creşterea transaminazelor este efectul alterării permeabilităţii membranei celulare din cauza dezechilibrului masiv indus de stres. Nu s-au înregistrat modificări semnificative statistic ale valorilor LDH sau ale bilirubinei serice totale, comparativ cu lotul martor.

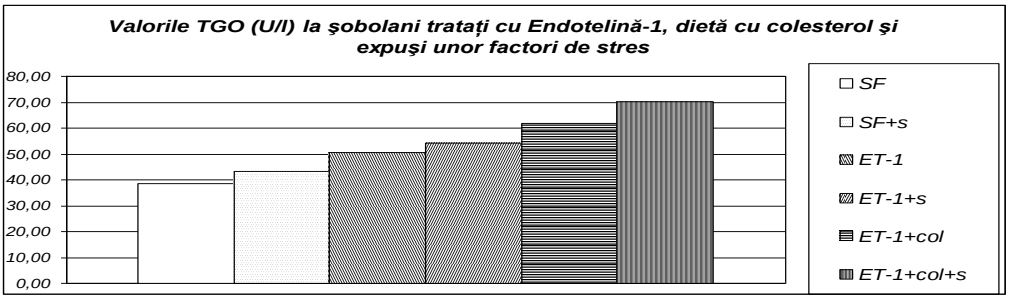

Fig. 2. Valorile TGO după 28 de zile

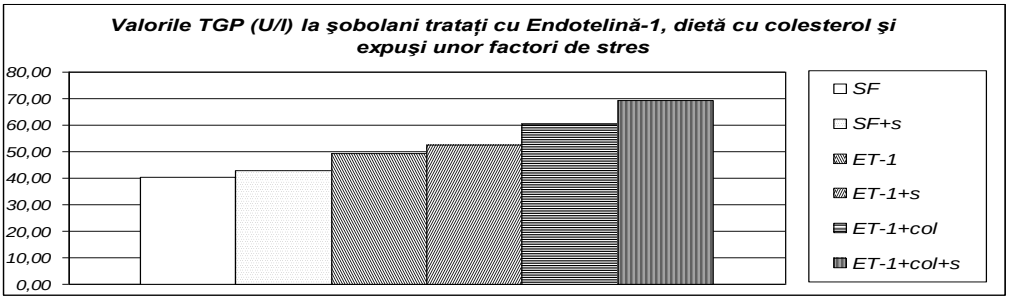

Fig. 3. Valorile TGP după 28 de zile

Pe de altă parte, s-a constatat scăderea trigliceridelor (fig. 7) şi creşterea colesterolului total (fig. 4), pe seama creşterii LDL-colesterolului (fig. 5) şi scăderea HDL-colesterolului (fig. 6). Efectele cele mai puternice au fost înregistrate la animalele cu HTA indusă experimental cu endotelină-1, cu dietă cu colesterol plus menţinerea în condiţii de stres. Modificările biologice sunt datorate stimulării induse de stres a axei hipotalamo-hipofizo-suprarenaliene şi a sistemului nervos simpatic, cu eliberarea secundară de catecolamine şi glucocorticoizi.

Răspunsul la stres include multipli hormoni: ACTH, catecolamine, ADH, angiotensină, glucagon şi GH. Creşterea colesterolului este atribuită creşterii corespunzătoare a sintezei acestuia prin mobilizarea lipidelor din depozite datorită activităţii simpatice şi a axei hipotalamo-hipofizo-suprarenaliene. Trigliceridele scad având în vedere relaţia inversă dintre acizii graşi liberi şi trigliceride, acestea din urmă reprezentând o sursă rapidă de energie.

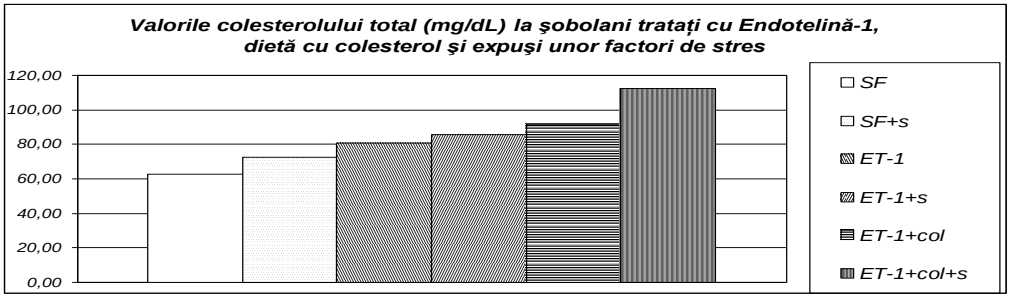

Fig. 4. Valorile colesterolului total după 28 de zile

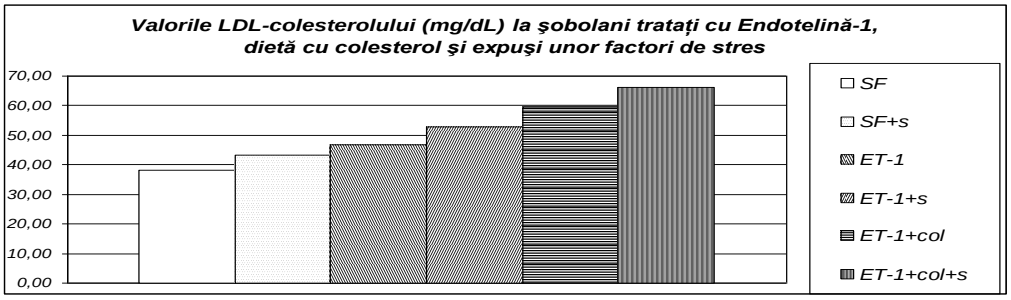

Fig. 5. Valorile LDL-colesterolului după 28 de zile

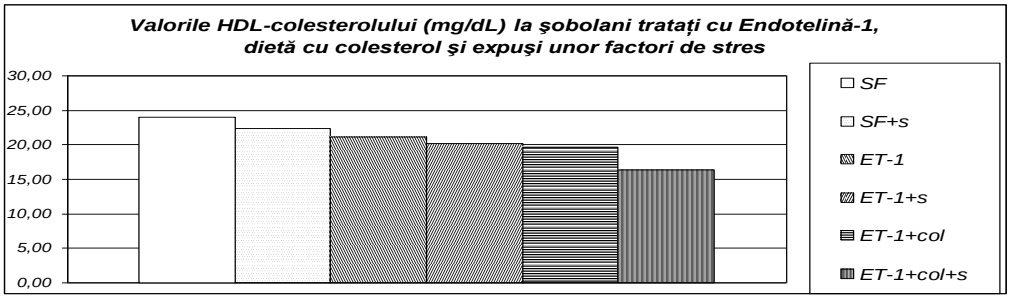

Fig. 6. Valorile HDL-colesterolului după 28 de zile

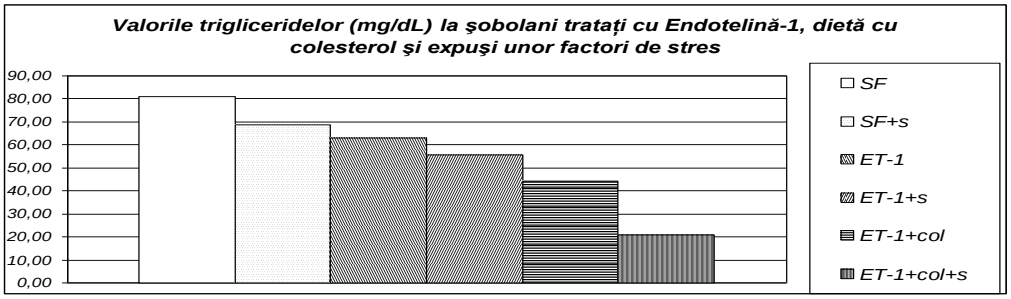

Fig. 7. Valorile trigliceridelor după 28 de zile

CONCLUZII

În condiţiile experimentale realizate, s-a constatat că, după expunerea la un stres cronic, şobolanii Wistar cu HTA indusă de endotelina-1 au prezentat alterarea funcţiei hepatice (creşterea TGO şi TGP), la toate loturile analizate, comparativ cu lotul martor. Pe de altă parte, s-a constatat scăderea trigliceridelor şi creşterea colesterolului total, pe seama creşterii LDL-colesterolului şi scăderea HDL-colesterolului. Efectele cele mai puternice au fost înregistrate la animalele cu HTA indusă experimental, cu dietă cu colesterol plus menţinerea în condiţii de stres.

Condiţiile de stres cronic în care au fost menţinute animalele cu HTA indusă experimental cu endotelină-1 au determinat o creştere a valorilor tensionale semnificativ statistic mai puternică comparativ cu nivelurile acestui parametru la animalele neexpuse la stres. Cele mai importante creşteri ale tensiunii arteriale au fost înregistrate la animalele de laborator expuse stresului şi prezentând, în acelaşi timp, dislipidemie indusă experimental.

COMPARATIVE CLINICAL-EPIDEMIOLOGICAL ASSESSMENTS OF ROAD TRAFFIC ACCIDENTS. OBSERVATIONS IN EMERGENCY ROOMS FROM THREE COUNTIES OF MOLDAVIA, ROMANIA, DURING 2005-2010 (Abstract). **Aim:** to assess road traffic injuries according to some descriptive parameters. **Material and methods:** The study was carried out on a series of 5374 patients admitted to emergency rooms at Iasi (n=3050), Botosani (n=1187), and Vaslui (n=1137), between 2005 and 2010. **Results**: Most frequently, the patient was a young, male adult, with cranial cerebral trauma, leg fracture, forearm contusion, or polytrauma, presenting to the emergency room most commonly in the month of August, weekends, and interval noon – dawn interval. **Conclusions**: The impact of road trauma epidemic would facilitate a better adaptation of the medical staff to case dynamics and increase the efficacy of primary prevention programs. **Key words**: ROAD TRAUMA EPIDEMIC, INJURY, EPIDEMIOLOGY

În Uniunea Europeană, accidentele de circulație sunt principala cauză de deces în rândul turiştilor, reprezentând 50% din cauzele de deces, 20% din internările în spital şi 30% din cazurile unui serviciu de urgențe (1, 2, 3, 4).

În România, circulația rutieră a cunoscut o dezvoltare semnificativă în ultimii 17 ani. În condițiile în care infrastructura rutieră a rămas în aproximativ aceiaşi parametri ca în anii 1990, parcul de autovehicule şi numărul posesorilor permiselor de conducere s-au dublat (peste 5 milioane). Peste 2500 de persoane decedează anual în evenimente rutiere, echivalentul dispariției de pe hartă a unei localități rurale de mărime medie, iar 6000 de persoane sunt rănite (5, 6).

Rapoartele statistice ale Poliției Rutiere arată că cele mai multe accidente rutiere din România sunt cauzate de viteza neregulamentară şi neadaptarea acesteia la con-

diţiile de drum (29%), urmate de incidentele provocate de pietonii care traversează strada fără să se asigure (25%), depăşirea neregulamentară (12%), neacordarea de prioritate (9%).

MATERIAL ŞI METODE

Studiul a fost efectuat, în perioada 2005-2010, pe un lot total de 5374 pacienţi din care internaţi în secţiile U.P.U. ale Spitalului Clinic de Urgenţe „Sf. Ioan" Iaşi (n=3050), Spitalului Judeţean Botoşani (n=1187) şi Spitalului Judeţean Vaslui (n=1137). Cazuistica din cei 6 ani calendaristici corespunde unui număr total de 2191 zile de activitate medicală în UPU, timp în care s-au inregistrat, în medie, 1,39 cazuri pe zi la U.P.U. Iaşi, 0,54 la U.P.U. Botoşani şi 0,51 cazuri pe zi prezentate în U.P.U. Vaslui. Culegerea datelor a fost realizată retroprospectiv, utilizându-se registrele de internare şi externare ale spitalului şi foile de observaţie ale pacienţilor. Prelucrarea datelor s-a efectuat cu ajutorul programului de statistică SPSS 16.0.

REZULTATE ŞI DISCUŢII

1. Incidenţa anuală a cazurilor de accidente de trafic rutier, în judeţele Iaşi, Botoşani şi Vaslui, în perioada 2005-2010, a arătat o tendinţă crescătoare a numărului de cazuri, în toate judeţele, cu un maxim în anul 2008, de 673 cazuri la Iaşi; 240 la Botoşani şi 285 cazuri la Vaslui (fig. 1). În ultimii doi ani luaţi în studiu au fost înregistrate mai puţine cazuri de accidente rutiere, aspect observat şi de alţi autori şi pus pe seama implementării mai eficiente a unor programe de prevenţie a accidentelor de circulaţie în general şi a celor rutiere, în special (3, 4, 5).

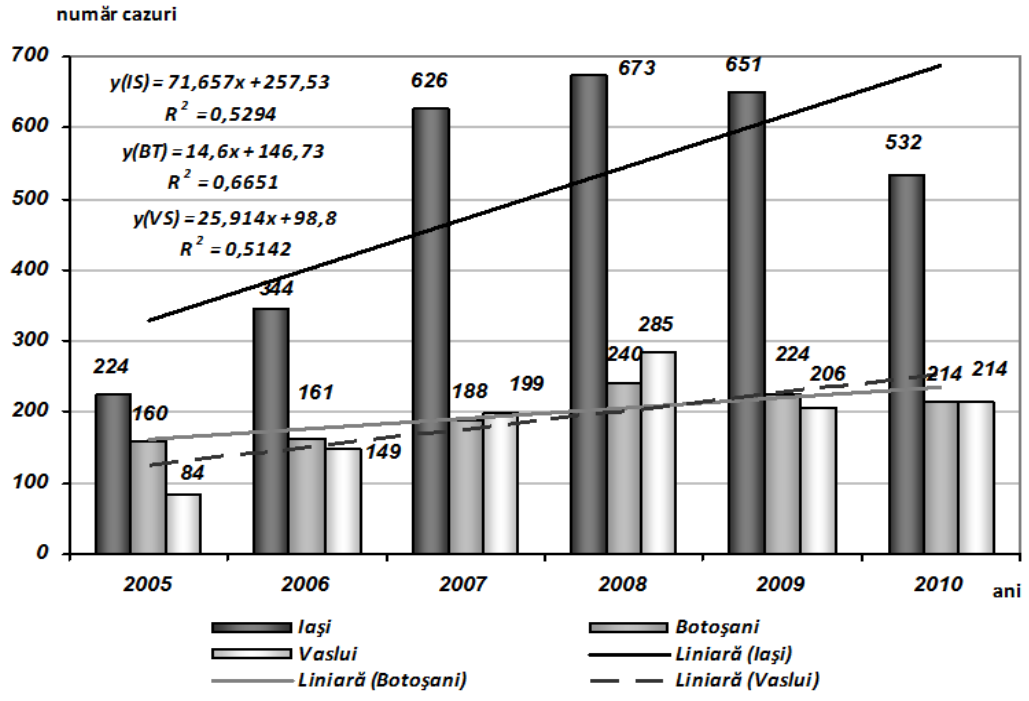

Fig. 1. Repartiţia anuală a numărului de cazuri de accidente de trafic rutier, comparativ în judeţele

Iaşi, Botoşani şi Vaslui, în perioada 2005 - 2010

2. Repartiția pe sex a cazurilor de accidente rutiere, în județele Iaşi, Botoşani şi Vaslui, în intervalul de timp studiat, arată că sexul masculin a fost mai frecvent implicat (cu un maxim de 67,2% în Vaslui), față de feminin (39,2% maxim în Iaşi), cu un raport bărbați / femei (calculat cumulativ pentru întreg lotul studiat şi toții anii) de aproximativ 1,8 (fig. 2).

Şi alți autori, în cercetările lor, publicate în țară şi străinătate, evidențiază faptul că bărbații sunt mai frecvent implicați în accidente rutiere decât femeile, luând în considerație atât riscul ocupațional (angajații conducători auto bărbați sunt mai numeroşi), cât şi faptul că temperamentul feminin este mai prudent, atât la volan, cât şi ca pieton (3, 5, 6, 8).

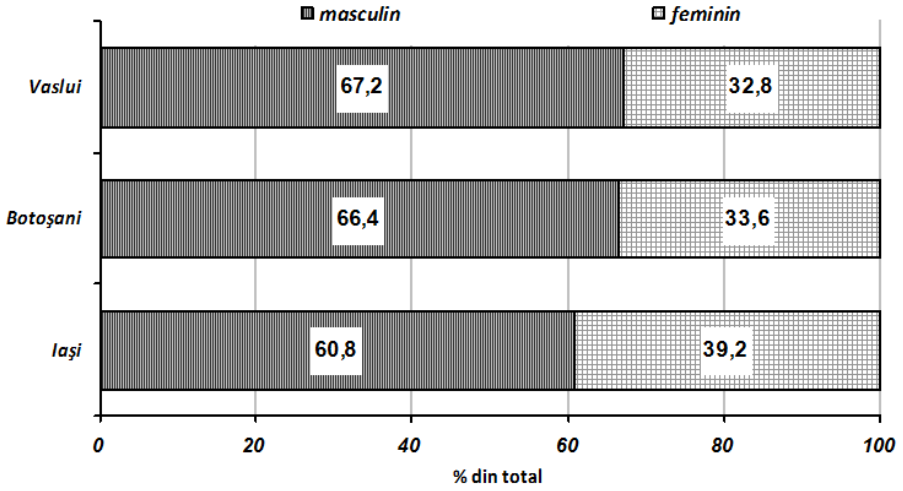

Fig. 2. Repartiția pe sex a numărului de cazuri de accidente de trafic rutier, comparativ în județele Iaşi, Botoşani şi Vaslui, în perioada 2005 - 2010

3. Distribuția pe grupuri de vârstă. Analiza de varianță ANOVA şi testul Bonferroni au arătat că, la Botoşani, au existat diferențe semnificative în ceea ce priveşte prezența în UPU a cazurilor din grupurile de vârstă 19-30 ani, comparativ cu cele peste 61 ani (F=4,947; p=0,000588). La Iaşi, aceleasi teste au arătat diferențe semnificative între toate grupurile de vârstă (F=19,197; p=0,000), grupul de vârstă <18 ani fiind exclus din această comparație. La Vaslui, diferențe semnificative au fost între grupurile de vârstă < 18 ani şi 19-30 ani (F=3,355; p=0,009681) (tab. I, II).

Şi alte cercetări, efectuate în diferite ţări, prezintă rezultate similare cu cele obţinute de noi, referindu-se la faptul că grupul de vârstă al adultului tânăr este cel mai frecvent implicat în producerea accidentelor rutiere (3, 8, 9, 10).

4. Repartiţia cazurilor în relaţie cu data, ziua şi ora prezentării. Analizând data prezentării pacienţilor în UPU, dacă s-a comparat cu o distribuţie egală / uniformă, s-au observat diferenţe semnificative între lunile anului, atât la Botoşani ($\chi2$=99,224, p=0,000), cât şi la Iaşi ($\chi2$=64,027, p=0,000) şi Vaslui ($\chi2$= 74,050, p=0,000), cu o frecvenţă mai mare în august (Botoşani şi Vaslui) şi octombrie (Iaşi).

Diferenţe semnificative, comparativ pe zilele săptămânii, apar doar la Iaşi ($\chi2$=14,655, p=0,023) şi la Vaslui ($\chi2$=19,133, p=0,004). S-a constatat o frecvenţă mai mare a accidentelor în zilele de weekend, cu o medie de aproximativ 2 cazuri / zi, în toate cele trei judeţe.

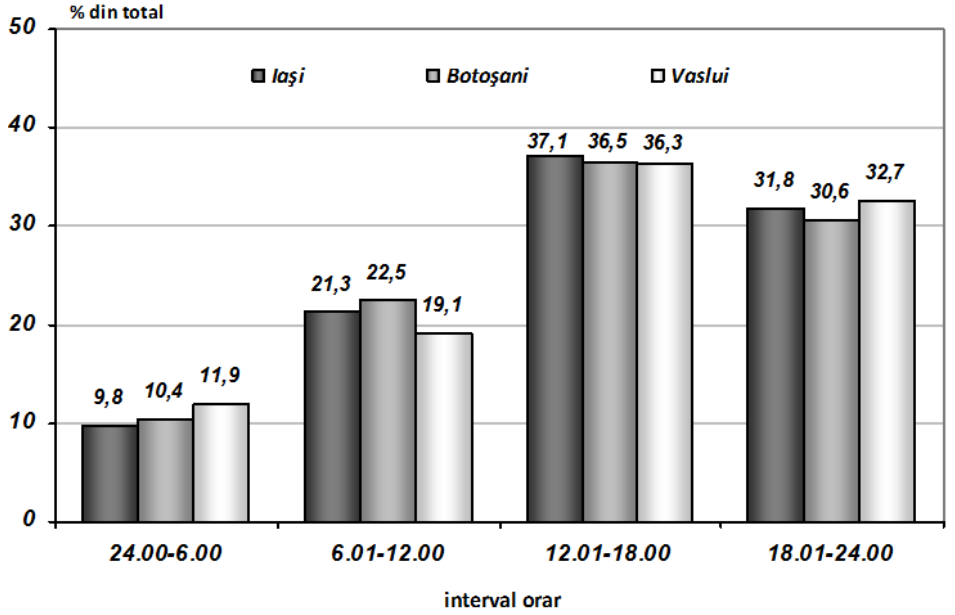

Fig. 3. Repartiţia în relaţie cu intervalul orar al prezentării în U.P.U. a cazurilor de accidente rutiere, comparativ în judeţele Iaşi, Botoşani şi Vaslui, în perioada 2005 - 2010

Referitor la intervalul orar al prezentării pacienților accidentați în traficul rutier, am constatat faptul că cele mai multe cazuri au fost întâlnite între orele 12.01 18.00, cu un maxim de 37,1% la Iași, maximul intervalului orar de 18.01-24.00 fiind constatat la Vaslui (32,7%); 6.01-12.00, la Iaşi (22,5%); 24.01-6.00 cu maxim tot la Vaslui (11,9%) (fig. 3).

Deci, distribuția cazurilor pe intervale de câte şase ore, începând cu ora zero, a evidențiat proporții similare cu cele din literatura de specialitate (2, 3, 6, 7) şi a fost semnificativ diferită față de o distribuție simetrică, aşteptată ($p<0,001$). Aceste rezultate pot fi explicate prin intensitatea crescută a traficului rutier în județul Iaşi, în perioada de zi (ocupațional, pietonal), iar pentru primele ore ale dimineții, cât şi ale amurgului, prin efectuarea navetei între cele trei județe.

5. Distribuția leziunilor în funcție de localizare a arătat faptul că traumatismele cranio-cerebrale (TCC) şi cele craniofaciale (TCF) au fost cel mai frecvent întâlnite, în toate cele trei județe (Iaşi – 829 cazuri; Botoşani – 598; Vaslui - 500), dar şi leziunile de tip fracturi ale gambei, contuziile toracelui şi ale membrelor superioare au fost situate în primele locuri (tab. III).

TABELUL III

Distribuția leziunilor, în funcție de localizare, ale cazurilor de accidente rutiere, comparativ în cele trei județe studiate

Tipul leziunii	Jud. Iaşi		Jud. Botoşani		Jud. Vaslui	
	Nr.	%	Nr.	%	Nr.	%
TCC, TCF	829	27,2	598	50,4	500	44,0
Comoții cerebrale, leziuni intracraniene	145	4,8	81	6,8	119	10,5

Contuzii gambă, picior	321	10,5	82	6,9	272	23,9
Contuzii membre superioare	498	16,3	151	12,7	253	22,3
Luxații, entorse, întinderi	365	12,0	77	6,5	36	3,2
Plăgi deschise	343	11,2	200	16,8	297	26,1
Excoriații multiple	177	5,8	47	4,0	247	21,7
Leziuni acute organe interne abdominale	57	1,9	22	1,9	25	2,2

CONCLUZII

Accidentele rutiere, în județele Iaşi, Botoşani şi Vaslui, prin numărul mare de cazuri, se încadrează în aşa-numita *epidemie traumatică rutieră*, având în comun un profil al pacientului care se calchează pe următoarele caracteristici: adult tânăr, frecvent bărbat, care se prezintă în U.P.U cel mai adesea în luna august, în weekend, în intervalul orar 12-18, cu politraumatism, frecvent TCC, fractură de gambă, contuzie toracică şi / sau abdominală.

Cunoaşterea impactului traumatismelor prin accidente rutiere va facilita adaptarea U.P.U. la dinamica anuală a cazurilor, va permite o mai rapidă orientare a personalului medical în fața urgențelor medicale şi chirurgicale şi, pornind de la datele obținute, se pot implementa programe eficiente de prevenție primară a accidentelor rutiere, în cele județe studiate.

ASSESSMENT OF THE DYSHOMEOSTASIS OF THE STOMATOGNATHIC SYSTEM IN THE ELDERLY (Abstract) : Old age (over 65) is considered to be a fragile stage, a stage of involution and regression and very often raises multiple psychological and clinical problems. Just like the other stages of life, old age is characterized by certain psychological features, a certain psychical state that depends of the nervous central system's state and of past experiences of life as well. The effects of aging on the stomatognat system can be identified at all the system's elements ; it is sometimes difficult to differentiate them from the physiological or pathological phenomena and their mechanisms. After analyzing the dishomeostasis of the stomatognat system from a gerontologic perspective it resulted that the stomatologic geroindex established in relation to the dental chronology is dominated by the prevalence of mono or bi maxillary total edentation to which stomatologic treatment is associated. In order to be a success, from a therapeutic, functional and aesthetic point of view, specific techniques must be used on elderly patients. These techniques have to be integrated into the aging process and must be related to the elderly patient's energy to adjust to changes, an energy that decreases with the passing of time. **Key words**: DISHOMEOSTASIS, ELDER PATIENT, STOMATOGNAT SYSTEM, GERONTOSTOMATOLOGY

Gerontologia, domeniul al cunoştinţelor despre procesul de îmbătrânire umană a acumulat experienţă în contextul dezvoltării doctrinelor fiziologice şi mai târziu în dezvoltarea cunoştinţelor biologiei şi medicinei cu multă vreme înainte de epoca noastră. Observaţiile au permis să se strângă informaţii din viaţa socială, privind bătrâneţea, ca vârstă a înţelepciunii, vârsta bilanţurilor, cu tendinţă de împăcare cu lumea, de detaşare treptată de magma ei fierbinte.

Bătrâneţea şi problematica sa a fost semnalată din înscrisurile antice cu mult înainte de perioada sumeriană şi aprofundată pe linia filozofică, apoi pe ramurile sale ştiinţifice, pînă azi, pe măsură ce cunoaşterea a luat locul intuiţiei sau speculaţiilor filozofice. Însă toate aceste observaţii sunt străbătute de aceleaşi idei că : *îmbătrînirea* şi *moartea* nu sunt decât accidente, viaţa fiind eternă. Îmbătrânirea a fost considerată o pedeapsă a spiritului în astrologia şi magia timpului.

Efectele îmbătrânirii la nivelul sistemului stomatognat, atinge toate elementele sistemului, uneori greu de diferenţiat între fenomenele fiziologice şi cele patologice, cât şi a mecanismelor lor exacte.

Gerontostomatologia s-a impus astfel ca o disciplină de sine stătătoare cu concept, strategie şi metodologie deja precizate în contextul medicinei stomatologice, orientată pe integrarea bio-psiho-socială.

Abordarea sistemului stomatognat, impune probleme specifice şi particularităţi care se corelează cu aspectele involutive generale şi locoregionale.

De la Hippocrat încoace, evaluarea comparativă organism uman- sistem stomatognat a cunoscut numeroase precizări care iniţial au fost constatate ca simptomatologie, ulterior au fost explicate pe baze ştiinţifice din ce în ce mai perfecţionate tehnologic.Cu toate acestea o abordare analitică aşa cum este realizată încă de medicina modernă, nu a permis studii deosebit de performante din punctul de vedere al sistematicii biologice, iar studiile sinergetice sunt încă limitate de exigenţele etice şi financiare care influenţează aplicarea lor în practica medicală şi cu atât mai mult în stomatologie.

Evaluarea vârstnicului a prezentat în contextul dezvoltării gerontostomatologiei noi faţete ale particularităţilor morfofuncţionale cu implicaţii directe în abordarea terapeutică a cazurilor.

Cu toate noutăţile importante în domeniile gerontologiei şi geriatriei, homeostazia vârstnicilor rămâne o problemă cu multe necunoscute.

Sistemul stomatognat sub aspectul abordării homeostazice a fost raportat în premieră de şcoala ieşeană de stomatologie, care a precizat corelaţiile intra şi extra sistemice ce conduc la homeostazie sau dishomeostazie în contextul teoriei "etiopatogenice integrative" (1,2).

OBIECTIVELE LUCRĂRII

Măsura în care formele clasice ale dishomeostaziei sistemului stomatognat la vârstnici se succed sau se interpătrund, şi care sunt metodele cele mai eficiente de evaluare a sistemului stomatognat la vârstnici, avându-se în vedere particularităţile de management impuse de această categorie de vârstnici.

Cunoscându-se faptul că vârstnicului îi sunt caracteristice limite largi de variabilitate în privinţa simptomatologiei sistemului stomatognat, în contextul homeostatic, se impune o conduită sistematică de investigare şi terapeutică pe considerente gerontostomatologice.

Gerontostomatologia a şi precizat o serie de aspecte manageriale incluse în contextul evaluării sistemului stomatognat la vârstnici.

MATERIAL ŞI METODĂ

Homeostazia şi dishomeostazia sistemului stomatognat sunt achiziţii recente ale medicinei stomatologice care au generat şi mai generează controverse pe tărâmul semantic, conceptual şi chiar în contextul pragmatic al acestei specialităţi.

Homeostazia şi dishomeostazia sunt două concepte importante pentru organismul uman şi implicit sistemul stomatognat considerat ca subsistem.

Homeostazia reprezintă în esenţă *–înţelepciunea organismului* (7) ce poate fi interpretată în raport de factorii de referinţă, căile de realizare, componentele sistemelor homeostazice şi factorul cronologic.Formele homeostaziei organismului viu sunt : cronobiologice ; genetică şi imunocelulară ; morfologică şi funcţională ; nervoasă ; neuropsihică. (6).

Cunoaşterea etapelor dishomeostaziei(*de susceptibilitate, preclinică, de debut, manifestă, de decompensare*) care *caracterizează orice altă maladie*, permite aprecierea evolutivă şi prognostică a dinamicii sistemului stomatognat, raportată la conceptul adaptabilităţii presupus de procesul homeostazic.

Studiile privind îmbătrânirea sub diferitele ei aspecte-*senescenţă- senectute- senilitate* - precizează următoarele aspecte : în raport cu evoluţia ontogenetică, îmbătrânirea este un proces dinamic complex cu debut latent şi la vârste fragede ; fenomenul îmbătrânirii nu este linear şi identic la populaţia de aceeaşi vârstă, şi se caracterizează printr-o variabilitate ce îmbină fenomenele de homeoreză cu cele de boală ; variabilitatea gerontologică poate fi stabilită pe trei nivele în raport de geroindex şi poate exprima o

TABELUL I
Repartiţia pe vârste şi sexe a pacienţilor examinaţi

VÂRSTA	SEX FEMININ	SEX MASCULIN	LOTURILE DE STUDIU
54-64 ANI	13	18	LOTUL I
65-74 ANI	11	12	LOTUL II
75-84 ANI	2	5	LOTUL II
PESTE 85 ANI	1	1	LOTUL II

îmbătrânire fiziologică, îmbătrînire nefiziologică şi îmbătrănirea patologică. După aspectul geriatric există o polipatologie somato-psihică ce evoluează pe căile homeostaziei-dishomeostaziei.

Aspectele îmbătrănirii generale se interrelaţionează fără dubiu cu involuţia sistemului stomatognat, care este guvernat de aceleaşi legi biologice.

În contextul aprecierii sistemului stomatognat al vârstnicilor se impune reconsiderarea criteriilor de evaluare şi terapeutică în raport de particularităţile gerontologice şi geriatrice stipulate de studiile nosologice şi particularităţile gerontostomatologice care sunt precizate în multe cercetări.

Categoria vârstnicilor cuprinde o mare variabilitate de criterii : domiciliari/ instituţionalizaţi ; valizi / invalizi / handicapaţi.

Această variabilitate se materializează şi în contextul stomatologic, fiind pacienţi cu diferite forme de patologie a sistemului stomatognat.

Au fost examinaţi 63 pacienţi de vârste cuprinse în contextul gerontologic între 54 şi peste 85 de ani, cu diagnosticul stării generale precizat în contextul explorării comportamentale indicate de stomatolog, sau medicul generalist.

Cei 63 de pacienţi examinaţi au fost împărţiţi în două loturi :

Lotul martor I - reprezentat de pacienţi cu vârste cuprinse între 54 şi 64 ani-31 pacienţi-49,20%.

Lotul de studiu II - reprezentat de pacienţi cu vârste cuprinse între 65 şi peste 85 de ani-32 pacienţi-50,80%.

Scopul examinării a constat în decelarea simptomatologiei ce poate aparţine factorilor suprasistemici, intrasistemici şi reflectă interrelaţia lor.

În contextual evaluării pacientului gerontostomatologia a precizat coordonatele manageriale sistematizate în raport de cerinţele vârstnicului şi conceptual gnatoprotetic cu orientare sistemică integrativă.

Factorii suprasistemici sunt factorii psihici, neurologici, endocrine, boli de sistem, boli metabolice ce duc la elementele sistemului (dinte, parodonţiu, muşchi, ATM, oase) dând naştere la sindromul disfuncţional al sistemului stomatognat.

Sistemul stomatognat cuprinde factorii intrasistemici-malocluzii, asimetrii funcţionale, asimetrii morfologice, obiceiuri vicioase şi patologie specifică.

REZULTATE ŞI DISCUŢII

Evaluarea dishomeostaziei sistemului stomatognat a parcurs etapele esenţiale preconizate de conceptual gnatoprotetic, fiind orientată pe examinarea semiologică sistemică : anamneză, stare generală, stare locală (extraorală, intraorală), examinări complementare în vederea precizării geroindexului (general, loco-regional, local) şi a necesităţilor terapeutice.

Examinarea prodiagnostică cu scop final, instituirea unei reechilibrări terapeutice în contextual sistemic au fost permanent comparativ orientate pe criteriile biologic, biomecanic, socio-economic, la care s-a adăugat încă o axă constituită din deducerea aspectelor generale şi implicit stomatognate : va-

riabilitate, fragilitate, dependenţă.

Din punct de vedere gerontostomatologic această axă se raportează la aspectele esenţiale ale simptomatologiei vârstnicului.

Evaluarea anamnestică s-a axat pe precizări importante vizând datele generale comparate cu cele actuale, condiţii de mediu, familiale, nutriţionale, anamneza în raport cu simptomatologia dominantă şi de etapă terapeutică prezentă la momentul evaluării, anamneza familială şi aspectele comparative, loco-regionale şi locale prezente.

Examinarea generală a stării s-a realizat în contextual interdisciplinarităţii-cabinet gerontostomatologic → cabinet de familie → cabinet de specialitate → medic geriatrie.

În privinţa colaborării gerontostomatologie-geriatrie, datele atestă receptivitatea existentă pentru această linie, dar şi necesitatea perfectărilor de cadru.

În privinţa documentelor obiective pe care un pacient le poate prezenta în contextul gerontostomatologic şi care pot să ateste trecutul medical dar şi starea prezentă, cea mai ergonomică metodă s-a dovedit colaborarea cu medical curant generalist sau de specialitate.

Din punct de vedere al stării generale somato-psihice la pacienţii examinaţi s-a constatat următoarele afecţiuni generale manifeste :

- 14 cazuri-afecţiuni cardiovasculare : 22,22%,
- 5 cazuri afecţiuni gastro-entero-hepatice : 7,93%,
- 3 cazuri cu afecţiuni bronho-pulmonare : 4,76%,
- 2 cazuri cu afecţiuni reumatismale cronice : 3,17%,
- 4 cu afecţiuni renale : 6,34%.

Diagnosticul a fost efectuat în clinici medicale.

Modificările cervico-faciale şi intraorale la examenul loco-regional au evidenţiat semnele caracteristice afecţiunilor asociate şi cu aspectele de senescenţă patognomonice.

Simptomatologia constatată în evaluarea gerontostomatologică este edificatoare pentru diagnosticul de stare generală influenţată pe filiera suprasistemică.

Modificările constatate merg pe două axe :

- Manifestări comune mai multor afecţiuni generale (modificări de culoare-cianoză, paloare, congestie la nivelul tegumentelor şi mucoaselor) şi manifestări caracteristice patognomonice pentru unele afecţiuni generale ;
- Manifestări gerontologice conexe involuţiei bioreutice.

Importanţa semiologică a modificărilor de la nivelul sistemului stomatognat pentru analiza prodiagnostică a stării generale a fost semnalată de numeroşi autori. Relevante ni se par aspectele evolutive ale acestor modificări (agravarea sau reducerea intensităţii lor fiind concordantă cu stadiul de decompensare al afecţiunii generale dar şi cu vârsta, sexul şi predispoziţia constatată pe baza datelor anamnestice).

Aspectele de dishomeostazie au inclus şi modificările psihosomatice prezentate pe parcursul examinării proterapeutice, în scopul decelării particularităţilor de adaptare la varianta terapeutică preconizată.În condiţiile actuale reacţiile psihosomatice sunt dominate mai puţin de criteriul biologic, au prevalat aspecte socio-economice care domină existenţa jurnalieră a fiecărui vârstnic impunând o conduită frustrantă uneori (lipsa condiţiilor de reabilitare generală într-un context psihosocial neprotectiv).

Înţelepciunea vârstei recunoscută de-a lungul evoluţiei speciei a dovedit un model comportamental decisiv în asigurarea cooperării prodiagnostice.

Explicarea necesităţilor de investigare complexă a indus un comportament mai cooperant pentru pacienţii din lotul studiat în comparaţie cu cel martor, dominat de problematica recentei pensionări asociată cu sentimente mai acute de frustare şi inutilitate.

Dishomeostazia sistemului stomatognat în contextul gerontostomatologic a prezentat următoarele aspecte : prezenţa modificărilor involutive caracteristice vârstnicilor asociată cu afectarea stării generale şi afecţiunile pre-

dominante specifice cardiovasculare care prevalează în raport cu cele bronhopulmonare, şi alte tipuri de afecţiuni.

Afecţiunile gerontologice specifice involuţiei se asociază cu patologia de predispoziţie declanşată din perioada de maturitate şi presenescenţă, fapt ce impune o conduită profilactică mult mai bine supravegheată cu un cadru adecvat.

Geroindexul general stabilit este predominant supraunitar, semnalizând îmbătrânirea accelerată, în timp ce valorile subunitare-îmbătrânire întârziată, sunt rar întîlnite.

Analizând dishomeostazia sistemului stomatognat în contextul gerontologic constatăm geroindexul stomatologic stabilit în raport de coordonatele vârstelor biologică / cronologică dentară, dominată de prevalenţa edentaţiei totale uni sau bimaxilare, la care se asociază şi tratamente stomatologice.

O particularitate a evaluării gerontostomatologice este aceea că prevalează tratamentele iatrogenice din perioada matură sau de prenescenţă, ce au o influenţă majoră dishomeostazică.

Din punct de vedere al involuţiei biologice, adaptabilitatea se diminuează iar rezistenţa scăzută a elementelor stomatognate se asociază cu necesitatea trecerii bruşte de la o stare de edentaţie redusă la extinsă sau subtotală cu rol agravant pentru starea generală influenţată.Evaluarea prodiagnostică este dominată de conduita terapeutică, ceia ce necesită tranziţii şi temporizare pe conceptele protezării imediate sau precoce pentru a evita dishomeostazia.

Analizând dishomeostazia sistemului stomatognat în contextul gerontologic constatăm geroindexul stomatologic stabilit în raport de coordonatele vârstelor biologică / cronologică dentară, dominată de prevalenţa edentaţiei totale uni sau bimaxilare, la care se asociază şi tratamente stomatologice.

CONCLUZII

Evaluarea gerontostomatologică va trebui să se raporteze mai intens în contextul interdisciplinarităţii medicină generală stomatologie, în beneficiul pacienţilor vârstnici.

Evaluarea gerontostomatologică se impune a fi realizată în raport de căile şi formele de manifestare ale dishomeostaziei sistemului stomatognat, motivelor prezentării pacienţilor vârstnici li se adaugă comparativ şi doleanţele lor în raport de care se va adapta şi conduita terapeutică.

O evaluare atentă a parametrilor de adaptare a sistemului stomatognat ar permite o adaptare optimală, funcţională şi estetică pe parcursul tratamentului.

La vărstnici, problemele de recuperare funcţională şi estetică fiind supuse limitelor energiei de adaptare trebuie statutate din perioada evaluării sistemului stomatognat.

E-TEST QUANTITATIVE DETERMINATION FOR EVALUATING *NEISSERIA GONORRHOEAE* RESISTANCE (Abstract): Thanks of underreported and of difficulties of isolation, antibiotic susceptibility profile of *N. gonorrhoeae* strains circulating is not sufficiently known in our country as well in the Suceava county. In addition, WHO' experts recommended the establishment of MIC (minimum inhibitory concentration) values using E-test strips, completing the database at the European level. **Aim**: To determine the type of resistance of *N. gonorrhoeae* strains by E-test in patients with gonorrhoea in Suceava county, in the 2009 -2010 period. **Material and method**: We tested the sensitivity of 32 strains of *N. gonorrhoeae* isolated using classical algorithm and E-test strips according with CLSI 2008 *(Clinical and Laboratory Standard Institute*) standard. We tested the sensitivity for penicillin, amoxicillin, augmentin, clarytromycin, tetracycline, ceftriaxone, ciprofloxacin, and spectinomycin. Production of β-lactamases was performed using API-NH test (*Neisseria-Haemophylus-Biomerieux*). **Results**: 96.9% strains were sensitive for ceftriaxone and spectinomycin, each 10 strains (31.2%) were resistat for penicillin and tetracycline, 34.5% strains were sensitive for amoxicillin, 37.5% sensitive for ciprofloxacin, and 13/32 strains (40.6%) were sensitive for augmentine. 7 strains were ß–lactamases positive and sensitive to all antibiotics, excepting penicillin and tetracyclin. Our results, especially the low rate of sensitivity for penicillin and tetracycline (68.8%) were similar with other from Asia, America or Africa, including Iaşi region. **Conclusion**: Our results demonstrated for first time in the studied aria, using E-test strips, the level of resistance of *N. gonorrhoeae* offering useful informations for clinicians in order to treat the patients with ceftrixone and spectinomycine as empirical treatment, and for other antibiotics, according with antibiogram results. **Key words**: *NEISSERIA GONORRHOEAE*, E-TEST, MIC, SENSITIVITY, RESISTANCE

În prezent, în România, nu se cunosc morbiditatea, incidenţa, prevalenţa sau spectrul de sensibilitate la antibiotice şi circulaţia tulpinilor rezistente de *Neisseria gonorrhoeae*. În general, incidenţa gonoreei este subraportată în România, inclusiv în judeţul Suceava, în principal prin lipsa de adresabilitate a pacienţilor care preferă anonimatul sau/şi tratarea infecţiilor cu transmitere sexuală prin eludarea sistemului de supraveghere al bolilor transmisibile. Datorită subraportării şi dificultăţilor de izolare binecunoscute, profilul de sensibilitate la antibiotice al tulpinilor circulante de *N. gonorrhoeae* nu este suficient de bine cunoscut. În plus, majoritatea autorilor recomandă stabilirea CMI, prin utilizarea benzilor E-test, în vederea completării bazei de date la nivel european (1,2).

Studiul a avut ca **obiectiv** stabilirea tipu-

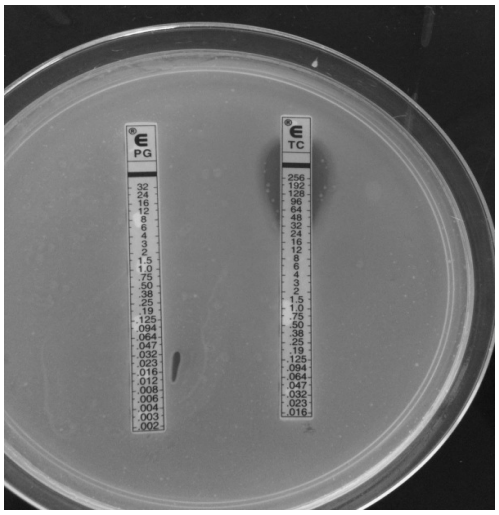

Fig. 1. E-test pe mediu GC agar bază completat cu 1% IsoVitaleX, fară hemoglobină pentru penicilină şi tetraciclină

lui de rezistenţă a tulpinilor de *N. gonorrhoeae*, prin E-test, la bolnavi cu gonoree din judeţul Suceava, în perioada 2009-2010.

MATERIAL ŞI METODE

În vederea selectării tulpinilor incluse în studiu, prelevarea, transportul şi conservarea probelor până la prelucrare s-au realizat ţinând cont de sensibilitatea gonococului la factorii de mediu ; tampoanele utilizate pentru recoltarea secreţiilor endo-cervicale, la femei şi a secreţiei matinale, la bărbaţi au fost însămânţate pe medii preîncălzite la 37°C, cu pH de 7,2-7,8. Am realizat frotiuri colorate Gram şi cu albastru de metilen care au fost examinate la microscopul cu obiectiv cu imersie pentru 32 probe (de la 6 femei şi 26 bărbaţi) recoltate în perioada octombrie 2009-august 2010. Am însămânţat produsele patologice pe medii nutritive (GC bază + 1% hemoglobină + 1% supliment nutritiv IsoVtalex, VITOX cu supliment selectiv VCN), plăcile fiind incubate în atmosferă de 5% CO_2 pentru 24-72 h la 37°C, 70% umiditate. Identificarea s-a realizat conform algoritmului clasic, cu truse comerciale API-NH (*Neisseria-Haemophylus - Biomerieux*), care au posibilitatea detectării concomitente şi a producerii de ß-lactamază. După identificare, tulpinile au fost stocate prin congelare la -25°C în bulion tripticază soia şi 20% glicerol (3). Am determinat valorile concentraţiilor minime inhibitorii (CMI) prin metoda E-test, tehnică recomandată de O.M.S ; suspensia utilizată a fost standardizată din cultura obţinută după 18 h cu etalonul 0,5 McFarland. Benzile E-test utilizate au fost : penicilină (CMI : 0,002-32 μg/mL), amoxicilină (CMI : 0,016-256 μg/mL), augmentin (CMI : 0.016-256 μg/mL) claritromicină (CMI : 0,016-256 μg/mL), tetraciclină (CMI μg/mL : 0,016-256), ceftriaxonă (CMI μg/mL : 0,002-32), ciprofloxacină (CMI μg/mL : 0,002-32), respectiv spectinomicină (CMI μg/mL : 0,064-1024) ; am repartizat câte două benzi pe fiecare placă (ex. penicilină- tetraciclină ; fig. 1).

Pentru stabilirea rezultatelor am utilizat criteriile de interpretare şi control, conform CLSI *(Clincal and Laboratory Standard Institute*) 2008 (tab. I) (4). Pentru asigurarea calităţii am utilizat tulpinile de referinţă de *N. gonorrhoeae* ATCC 49226, *Staphylo-coccus epidermidis* ATCC 12228 şi *Proteus mirabilis* ATCC 43071 pentru verificarea calităţii nutritive a mediilor de cultură şi a rezultatelor antibiogramei ; prelucrarea datelor, pentru cazurile de gonoree depistate şi confirmate s-a realizat utilizând programele *EpIData* şi *EpiInfo*.

REZULTATE

Am izolat 32 tulpini de *N. gonorrhoeae* de la 26 bărbaţi (81%) şi 6 femei (19%), respectiv de la cazuri suspecte de gonoree, pe baza definiţiei de caz (clinic şi epidemio-logic) ; 5 cazuri au fost confirmate numai prin frotiu.

Valorile CMI pentru penicilină, ampicilină, augmentin, tetraciclină, claritromicină, ceftriaxonă, ciprofloxacin, au fost transformate în procente (rate) de rezistenţă (tab.

TABELUL I

Valorile CMI, conform CLSI 2008 (4)

Antibiotic	Tulpină sensibilă CMI (µg/mL)	Tulpină intermediar sensibilă CMI (µg/mL)	Tulpină rezistentă CMI (µg/mL)
Penicilină	0,06	0,12-1	> 2
Ceftriaxonă	0,25	Nu există limite	Nu există limite
Ciprofloxacin	0,06	0,12-05	> 1
Spectinomicină	32	64	128
Tetraciclina	0,25	0,5-1	2-32

II) (3). În vederea exprimării rezultatelor obţinute este necesar să precizăm următoarele : producerea de penicinilază de către *N. gonorrhoeae* (PPNG - *Penicilinase Producing Ng*) este specifică tulpinilor β-lactamază pozitive ; rezistenţa cromosomală a *N. gonorrhoeae* (CMRNG – *Chromosomal Resistence Ng*) se defineşte pentru tulpinile care au CMI > 2 µg/mL şi sunt â-lactamază negative, iar CMI pentru tetraciclină este cuprinsă între 2-8 µg/mL ; rezistenţa la tetraciclină a *N. gonorrhoeae* (TRNG – *Tetracicline Resistante Ng*) se defineşte astfel : tulpinile au CMI > 16 µg/mL şi sunt β-lactamază negative (tab. I).

N. gonorrhoeae cu rezistenţa cromosomală la tetraciclină (*tetR*) are CMI pentru tetraciclină cuprinsă între 2-8 µg/mL şi CMI a penicilinei < 1 µg/mL ; rezistenţa la quinolone a *N. gonorrhoeae* (QRNG-*Quinolone Resistante Ng*) se defineşte pentru tulpinile care au CMI pentru ciprofloxacin > 1µg/mL ; în ceea ce priveşte ceftriaxona, valoarea CMI > 0,125µg/mL defineşte rezis-

TABELUL II

Rezultatele testării cu benzi E-test pentru tulpini de *Neisseria gonorrhoeae* izolate în perioada 2009-2010

Antibiotic	Rezistent % (pozitiv/total)	Intermediar % (pozitiv/total)	Sensibil % (pozitiv/total)
Ceftriaxona	**0 (0/32)**	**3,1 (1/32)**	**96,9 (31/32)**
Penicilina	**53,1 (17/32)**	**15,6 (5/32)**	31,2 (10/32)

* Rezistenta înaltă a fost corelată cu rezistenţa mediată plasmidic iar rezistenţa moderată/intermediară a fost corelată cu rezistenţa mediată cromosomal. Criteriile utilizate sunt cele ale CLSI (6)

tenţa pentru tulpinile de *N. gonorrhoeae*, iar rezistenţa la spectinomicină este definită pentru tulpinile care au CMI > 128 μg/mL (5).

Rezultatele testării prin utilizarea benzilor E-test, pentru cele 32 de tulpini de gonococ studiate sunt prezentate în tabelul II, iar criteriile de interpretare, conform CLSI 2008 sunt redate în tabelul III.

Dintre tulpinile studiate, şapte au fost β-lactamază pozitiv. Un număr de 17 tulpini au fost rezistente la penicilină (17/32), iar 19 dintre ele, la tetraciclină (19/32) (tab. II). La testarea sensibilităţii pentru penicilină, 7 tulpini (21,8%) au avut rezistenţă de nivel înalt, corelată cu rezistenţa plasmidică PPNG, iar 8 tulpini (25%) au fost definite CMRNG, deoarece mecanismul rezistenţă a fost mediat cromosomal (CMI >1 μg/mL) (tab. IV).

19 tulpini au fost rezistente la tetraciclină (tab. II) : 1l tulpini (37,5%) au avut rezistenţă înaltă, mediată cromosomal *tetR* (CMI >8 μg/mL), iar 4 tulpini (12,5%) au fost TRNG (CMI > 16 μg/mL), cu rezistenţă mediată plasmidic (CMI >1 μg/mL) (tab. IV). CMI 90 cu valoarea 32 μg/mL a indicat o rezistenţă de nivel înalt (tab. III).

TABELUL V

Valorile CMI 50 şi CMI 90 şi limitele CMI* de sensibilitate la antibioticele testate pentru *Neisseria gonorrhoeae* în Europa de Vest (12)

	CMI (µg/mL)	**CMI (µg/mL**	**CMI (µg/mL**
Antibiotic	**Limite**	**50%**	**90%**
Ceftriaxona	0,02-0,25	0,002	0,015
Penicilina	0,03-3,4	0,125	1
Tetraciclina	0,25-4	2	32
Ciprofloxacina	0,02-4	0,015	32
Spectinomiciina	0,064-64	8	64

*Criterii de interpretare conform CLSI (2008)

În ceea ce priveşte rezultatele testării pentru ciprofloxacin: 11 tulpini (34,4%) au fost rezistente (tab. II), fiind QRNG (CMI > 1 μg/mL) (tab. IV), iar 9 tulpini (28,1%) au prezentat o reducere a sensibilităţii la ciprofloxacin. CMI 90 cu valoarea 32 μg/mL a indicat o rezistenţă de nivel înalt, iar pentru CMI 50 am obţinut valoarea de 0,06 μg/mL (tab. III). O singură tulpină (3,1%) a prezentat o reducere a sensibilităţii la testarea pentru ceftriaxonă (tab. II). Deoarece concentraţia care defineşte reducerea sensibilităţii este o valoare CMI > 0,125 μg/mL (tab. I), nicio tulpină nu a fost rezistentă la ceftriaxonă. Rezultate similare s-au obţinut pentru spectinomicină: o singură tulpină (3,1%) a prezentat reducerea a sensibilităţii (tab. II). Nu am izolat nicio tulpină rezistentă la spectinomicină (respectiv cu CMI > 128 μg/mL). CMI 90 cu valoarea 64 μg/mL, indică o rezistenţă de nivel înalt, ceea ce corespunde unui CMI 50 de 8 μg/mL (tab. III).

DISCUŢII

Multirezistenţa a fost definită pentru următoarele asocieri: QRNG - PPNG; QRNG – TRNG; QRNG, PPNG şi TRNG. În timp ce pentru penicilină, tetraciclină, ceftriaxonă şi ciprofloxacin sunt criterii clare în ghidul pentru interpretarea sensibilităţii (4,6), pentru amoxicilină, augmentin şi claritromicină acestea nu sunt bine definite. Toate cele 7 tulpini ß-lactamază pozitive au fost rezistente la penicilină; producerea de β-lactamază nu a fost corelată cu reducerea sensibilităţii la alte antibiotice, exceptând tetraciclina.

Un număr mare de tulpini (20/32), respectiv 62,5%, au prezentat o reducere a sensibilităţii la ciprofloxacin. Scăderea sensibilităţii la antibiotice, în special pentru penicilină şi tetraciclină (68,7%) este comparabilă cu scăderea sensibilităţii tulpinilor raportată în Asia (74,3% pentru penicilină şi 98,4%, pentru tetraciclină); America (90% la penicilină şi 100% la tetraciclină); Africa (100% la penicilină şi 91,7% la tetraciclină) (7); Rusia (76% la penicilină şi 92% la tetraciclină) (8, 9, 10). Pentru zona de NE a ţării, în Iaşi, studii recente au determinat că 100% dintre tulpini sunt rezistente la penicilină şi 92,6%, la tetraciclină (11).

CMI 50 pentru penicilină a fost de 0,03 μg/mL, iar CMI 90, 16 μg/mL; valorile CMI 90 pentru tetraciclină (32 μg/mL), respectiv CMI 50 (2 μg/mL) sunt comparabile cu ţările din vestul Europei (tab. V); reamintim că CMI 50 şi CMI 90 (tab. III) sunt concentraţiile care inhibă 50%, respectiv 90% dintre tulpinile testate (concentraţia cea mai mică de antibiotic inhibitorie pentru un anumit procent din tulpinile testate).

Determinarea CMI este o necesitate practică, deoarece permite nu numai decizii terapeutice mai subtile, ci facilitează analiză epidemiologică a rezistenţei la agenţii antimicrobieni. Aceste valori permit orientarea rapidă către cel mai indicat medicament şi alegerea antibioticoterapiei de primă intenţie.

CONCLUZII

În zona noastră penicilina, tetraciclina, ciprofloxacina, claritromicina, amoxicilina şi augmentinul, nu pot fi folosite în tratamentul gonoreei, decât după rezultatul testării la antibiotice.

Continuarea la nivel regional şi naţional a supravegherii sensibilităţii la antibiotice este crucială în detecttaea emergenţei noilor fenotipuri de rezistenţă, dublată de monitorizarea variaţiei *pattern*-urilor de sensibilitate, în vederea adaptării schemelor terapeutice.

Evoluţia sensibilităţii la cefalosporine trebuie monitorizată obligatoriu, fiind singura clasă de antibiotice disponibilă în momentul de faţă pentru terapia sindromică în uretrita gonococică, pentru surprinderea apariţiei tulpinilor rezistente.

În continuare sunt necesare studii microbiologice extinse, inclusiv prin utilizarea markerilor de epidemiologie moleculară, pentru stabilirea mecanismelor de rezistenţa şi a modului lor de transmitere.

NOUTĂŢI

Urolitiaza pediatrică : îngrijirea chirurgicală curentă

Copiii reprezintă 1% din totalul pacienţilor cu urolitiază dar 100% din aceşti copii sunt consideraţi cu risc înalt de recidivă a formării de calculi astfel ncăt este crucial pentru ei sa primească o terapie care îi va feri de formarea de calculi în viitor. În plus, este necesară o supraveghere metabolică pentru a asigura p prevenţie sau o întârziere a recurenţelor. Cea mai adecvată terapie depinde de localizare, mărime, şi compoziţia calculilor, precum şi de anatomia tractului urinar, În centrele specializate ste accesibil întregul arsenal delitotripsie prin undă de şoc extracorporeală (ESWL), ureterorenoscopie (URS) şi nefrolitotomie percutană (PCNL) ; toate au la copil aceeaşi eficacitate şi siguranţă ca şi la adult (Straub M, Gschwend J, Zorn C, Pediatric urolithiasis : the current surgical management, *Pediatr Nephrol* 2010 ; 25 : 1239-1244).

IMMUNOHISTOCHEMIC STAINING FOR CK5/6 AND P63 SIGNIFICANCE IN PROSTATE PREMALIGNANT LESIONS AND ADENOCARCINOMA (Abstract): The morphologic information from usual hematoxiline-eosine staining are sometimes insufficient in certifying or excluding the adenocarcinoma of the prostate, cases who must be study by immunohistochemistry. **Aim**: The investigation of staining for CK5/6 and P63 in cases diagnosed with prostate adenocarcinoma associated with high grade prostatic intraepithelial neoplasia. **Material and methods**: The study was realized on 56 cases analyzed in Pathology Laboratory of Focşani Emergency Hospital. **Results**: We registered a positive correct diagnosis for atypical adenomatous hyperplasia in 86% of cases and for prostate adenocarcinoma grade 1 in 14% of cases. **Conclusions**: CK5/6 and P63 are useful markers for elucidating a positive false diagnosis for prostate adenocarcinoma grade 1. **Key words:** PROSTATE ADENOCARCINOMA, HIGH GRADE PROSTATIC INTRAEPITHELIAL NEOPLASIA, ATYPICAL ADENOMATOUS HYPERPLASIA, CK5/6, P63

Adenocarcinomul de prostată (ACP) reprezintă peste 90% din cancerele epiteliale prostatice. Forma bine diferenţiată este dificil de diferenţiat de o serie de leziuni benigne pe criterii morfologice (1). Neoplazia intraepitelială de prostată de grad înalt (HPIN) este leziunea premalignă definită ca leziune proliferativă intraepitelială atipică la nivelul acinilor şi ductelor (2). Distincţia majoră între aceste două leziuni este prezenţa stratului celular bazal în HPIN, care poate fi demonstrat folosind anticorpi specifici pentru celule bazale (3). Hiperplazia adenomatoasă atipică (AAH) este definită ca o proliferare atipică a acinilor mici din prostată, ce poate fi diagnosticată eronat ca ACP de grad 1 datorită aspectelor citologice şi arhitecturale.

CK5/6 este o citocheratină superioară ca specificitate în diferenţierea glandelor benigne de glandele maligne. Celulele bazale din acinii prostatici benigni exprimă CK5/6 (4). Gena P63 este un membru al familiei P53 şi a fost folosită pentru a evidenţia celulele bazale din epiteliul prostatic normal (5). P63 are o mare specificitate datorită fixării nucleare, în timp ce CK5/6 are un mare potenţial pentru reacţie nespecifică, având fixare citoplasmatică (6).

Scopul acestui studiu a fost să investigăm expresia fixării CK5/6 şi P63 în cazurile diagnosticate cu ACP asociat cu HPIN şi să

demonstrăm utilitatea imunohistochimiei (IHC) cu markeri pentru celule bazale ce contribuie la acurateţea diagnosticului pozitiv de AAH şi la elucidarea diagnosticului fals pozitiv de ACP grad 1.

Lucrarea a fost structurată conform următoarelor obiective : 1. selectarea unui număr de 56 cazuri diagnosticate cu ACP asociat cu HPIN ; 2. investigarea expresiei fixării CK5/6 şi P63 în cazurile studiate, în scopul diferenţierii ACP grad 1 de AAH ; 3. analizarea utilităţii IHC cu markeri pentru celule bazale în cazurile studiate.

MATERIAL ŞI METODĂ

1. Criterii de includere

Au fost incluse în studiu cazurile de prostatectomii radicale diagnosticate cu ACP asociat cu HPIN, înregistrate în Laboratorul de Anatomie Patologică al Spitalului Judeţean de Urgenţă Focşani în perioada octombrie 2006- noiembrie 2008.

2. Lotul de studiu

Din totalul cazurilor de 240 de prostatectomii radicale înregistrate în Laboratorul de Anatomie Patologică, au îndeplinit criteriile de includere un număr de 56 cazuri.

3. Analiza datelor

Pentru prelucrarea statistică a datelor din cadrul acestei cercetări s-a folosit softul statistic specializat *SPSS 13.0* şi Excel XP. S-au utilizat statistici descriptive, χ^2, corelaţii calculate la un prag de semnificaţie de 95%.

4. Tehnica de lucru

Am realizat un studiu IHC pe un număr de 56 cazuri de prostatectomii radicale diagnosticate cu ACP asociat cu HPIN, înregistrate în Laboratorul de Anatomie Patologică al Spitalului Judeţean de Urgenţă Focşani.

Studiul IHC a fost realizat pe baza folosirii a doi markeri pentru celule bazale prostatice : CK5/6 şi P63. Blocurile de parafină din materialul bioptic de studiat au fost secţionate la microtom la 2μ, secţiunile fiind apoi prelucrate pentru a fi colorate IHC. Pentru cercetarea IHC s-a folosit metoda avidină-biotină-peroxidază pe secţiunile obţinute din blocurile incluzionate la parafină. Reacţia pentru CK5/6 a fost realizată utilizând anticorpul Anti-Human citokeratin 5/6 monoclonal mouse clona D5/16B4, cod M7237(Dako, Danemarca). Reacţia pentru P63 a fost realizată utilizând anticorpul Anti-Human P63 protein monoclonal mouse, clona 4A4, cod M7247(Dako, Danemarca). Pentru ambii anticorpi s-a folosit ca anticorp secundar Biotinylated Goat Anti-Polyvalent (Ultra Vision Large Volume Detection System Anti-Polyvalent, Lab Vision Corporation), iar pentru evidenţierea antigenului s-a aplicat DAB (Liquid DAB Substrate Chromogen System cod K3466, Dako Danemarca).

Expresiile CK5/6 şi P63 la cazurile luate în studiu au fost analizate în grupuri morfologice ţinând cont de continuitatea fixării markerilor la nivelul celulelor bazale prostatice.

Astfel :

1. ACP ca şi control negativ a fost caracterizat prin absenţa pozitivării la CK5/6 şi P63, fiind considerată ca reacţie negativă (-).
2. AAH şi HPIN : cazurile în care pozitivarea la CK5/6 şi P63 a fost discontinuă au fost încadrate ca având reacţie uşor pozitivă (+), iar cazurile în care pozitivarea la CK5/6 şi P63 a fost continuă au fost considerate ca având reacţie moderat pozitivă (++).
3. Glandele benigne adiacente ca şi control pozitiv au fost caracterizate prin pozitivitate.

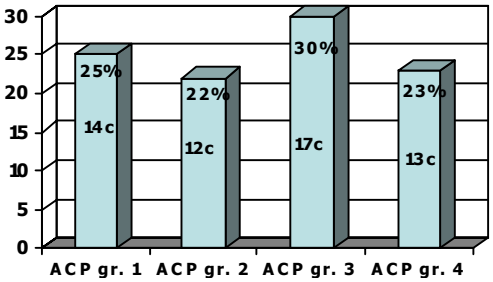

Fig. 1. Distribuţia cazurilor în raport de gradul Gleason şi criterii morfologice

varea la CK5/6 şi P63, care a fost etichetată ca reacţie intens pozitivă (+++).

Fixarea cu P63 a fost mai intensă decât fixarea cu CK5/6 şi a fost mai uşor de interpretat, fiind o fixare nucleară faţă de fixarea citoplasmatică a CK5/6. Au fost folosiţi 2 markeri pentru celule bazale prostatice pentru siguranţa diagnosticului pozitiv.

REZULTATE ŞI DISCUŢII

1. Structura lotului pe grupe de vârstă

Din analiza lotului de studiu de 56 cazuri diagnosticate cu ACP asociat cu HPIN s-a obţinut următoarea distribuţie a cazurilor pe grupe de vârstă: 28% (16/56) la grupa de vârstă 60-69 ani, 52% (29/56) la grupa de vârstă 70-79 ani şi 20% (11/56) la grupa de vârstă 80-89 ani. Rezultatele noastre evidenţiază o pondere crescută a cazurilor până la 80 de ani de 80% (45/56) care necesită IHC, comparativ cu ponderea scăzută a cazurilor peste 80 de ani de 20% (11/56) care necesită IHC. Evaluările comparative relevă: cazurile care necesită IHC sunt semnificativ statistic mai frecvente până la 80 de ani ($\chi^2=38,89$; GL=1; p=0,001) Acest aspect este explicat prin faptul că frecvenţa ACP grad 1 scade odată cu vârsta (7).

2. Structura lotului de studiu în funcţie de gradul Gleason pe criterii morfologice

În urma examinării fragmentelor tisulare colorate cu HE, încadrarea în raport cu gradul Gleason a fost următoarea: grad Gleason 1=25% (14/56); grad Gleason 2=22% (12/56); grad Gleason 3=30% (17/56); grad Gleason 4=23% (13/56) (fig. 1).

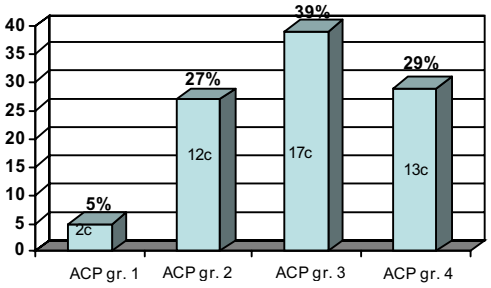

Fig. 2. Distribuţia cazurilor în raport de gradul Gleason şi criterii IHC

3. Structura lotului de studiu în funcţie de gradul Gleason după efectuarea IHC

Distribuţia cazurilor în raport cu gradul Gleason în urma efectuării IHC cu CK5/6 şi P63 a fost următoarea: grad Gleason 1=5% (2/44); grad Gleason 2=27% (12/44); grad Gleason 3=39% (17/44); grad Gleason 4=29% (13/44) (fig. 2).

Se constată că cel mai frecvent întâlnit este gradul Gleason 3 (39%), urmat de gradul Gleason 4 (29%) şi apoi de gradul Gleason 2 (27%). Gradul Gleason 1 este cel mai rar întâlnit (5%). Rezultatele noastre sunt similare cu datele din literatură (8).

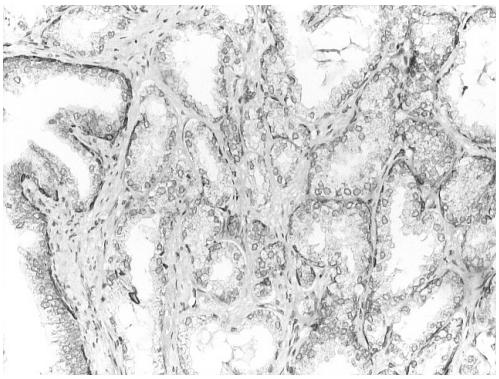

Fig. 3. HPIN asociat cu AAH, x10 CK5/6 fixare pozitivă discontinuă, reacţie uşor pozitivă(+)

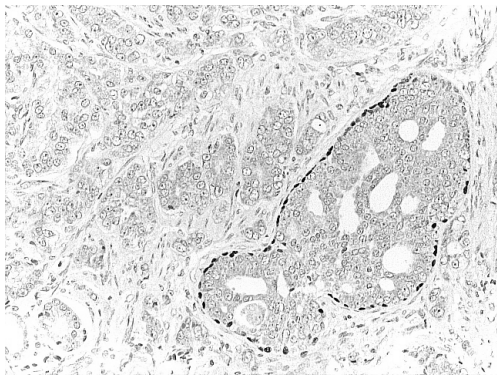

Fig. 4. HPIN asociat cu ACP grad 1, x10, P63 fixare negativă, reacţie negativă (-)

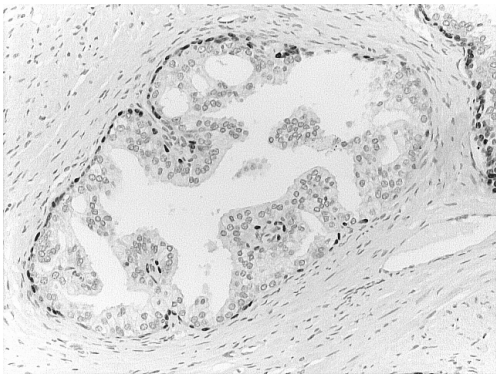

Fig. 5. HPIN, x10, P63 fixare pozitivă discontinuă, reacţie uşor pozitivă (+)

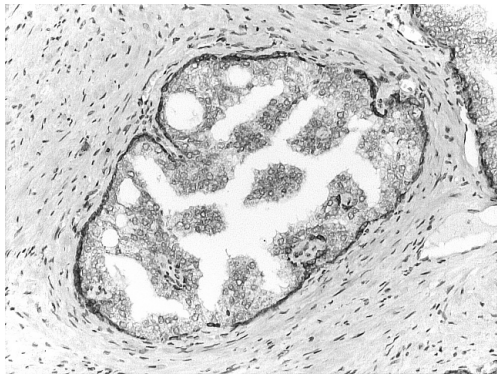

Fig. 6. HPIN, x10, CK5/6 fixare pozitivă continuă, reacţie moderat pozitivă (++)

4. Structura lotului de studiu în funcţie de reacţia fixării IHC cu CK5/6 şi P63

Examenul IHC a permis evidenţierea următoarelor aspecte în distribuţia cazurilor. Din cele 25% (14/56) cazuri diagnosticate ACP grad 1 prin coloraţie HE, 86% (12/14) au prezentat fixare pozitivă discontinuă fiind încadrate ca reacţie uşor pozitivă (+) şi diagnosticate AAH (fig. 3), iar celelalte 14% (2/14) au prezentat absenţa fixării markerilor, fiind încadrate ca reacţie negativă (-) şi diagnosticate ACP grad 1 (fig. 4). Restul cazurilor, reprezentând 75% (42/56) diagnosticate ACP grad 2,3,4 prin coloraţie HE, au relevat absenţa fixării markerilor fiind încadrate ca reacţie negativă (-).

În urma efectuării IHC, distribuţia cazurilor pe lotul de studiu a fost următoarea: 5% (2/44) au fost ACP grad 1, iar 95% (42/44) au fost ACP grad 2, 3 şi 4.

În ceea ce priveşte HPIN, 59% (33/56) au evidenţiat fixare pozitivă discontinuă (fig. 5), fiind încadrate ca reacţie uşor pozitivă (+), iar 41% (23/56) au prezentat fixare pozitivă continuă (fig. 6), fiind încadrate ca reacţie moderat pozitivă (++). Rezultatele noastre se pot compara cu cele relatate de Abrahams et al. 2003, care a raportat pentru HPIN o fixare pozitivă discontinuă a markerilor în 55% din cazuri şi o fixare pozitivă continuă a markerilor în 45% din cazuri (9).

Pentru control pozitiv glandele benigne adiacente au evidenţiat fixarea continuă a markerilor, fiind încadrate ca reacţie intens pozitivă (+++).

Din prelucrarea datelor statistice efectuate asupra celor două leziuni studiate, se pot face următoarele aprecieri.

1. Modificarea cazurilor ACP grad 1 după efectuarea IHC

În urma efectuării IHC cu markeri pentru celule bazale prostatice CK5/6 şi P63, cazurile diagnosticate cu ACP grad 1 au scăzut de la 25% (14/56) înainte de IHC la 5% (2/44) după IHC. Considerăm că este o diferenţă semnificativă statistic ($\chi^2 = 6,22$; GL = 1; p = 0,013) pentru confirmarea utilităţii IHC în acurateţea diagnosticului pozitiv de ACP grad 1.

2. Relaţia dintre ACP grad 1 şi AAH după efectuarea IHC

În urma efectuării IHC cu CK5/6 şi P63 s-a elucidat diagnosticul corect pozitiv de AAH în 86% din cazuri (12/14) şi de ACP grad 1 în 14% din cazuri (2/14). Rezultatele noastre demonstrează că este o diferenţă semnificativă statistic ($\chi^2 = 11,57$; GL = 1; p = 0,007) pentru confirmarea utilităţii markerilor CK5/6 şi P63 în diferenţierea ACP grad 1 de AAH, conform datelor din literatură (10).

Rezultatele noastre se pot compara cu cele relatate de Molinie et al., care a stabilit

un diagnostic corect pozitiv prin IHC în 91% din cazuri (11).

CONCLUZII

În prezentul studiu am explorat utilitatea IHC cu CK5/6 şi P63 în scopul elucidării diagnosticului fals pozitiv de ACP grad 1. Markerii pentru celule bazale prostatice se găsesc în celulele bazale ale glandelor benigne, dar sunt absente în ACP.

În studiul nostru grupul de cazuri ACP grad 1 asociate cu HPIN a avut aspecte morfologice de grad Gleason 1.

Folosirea IHC a condus la un diagnostic corect pozitiv de AAH în 86% din cazuri şi de ACP grad 1 în 14% din cazuri. Rezultatele noastre arată că un procent semnificativ de cazuri cu modificări morfologice de ACP grad 1 poate reprezenta AAH.

Considerăm că elucidarea diagnosticului pozitiv de AAH în 86% din cazuri este un argument pentru necesitatea utilizării IHC cu markeri pentru celule bazale în acurateţea diagnosticului pozitiv de AAH şi în elucidarea diagnosticului fals pozitiv de ACP grad 1.

STUDIU DESCRIPTIV PRIVIND EVALUAREA STATUSULUI BIOCHIMIC PE UN LOT DE 464 DE PERSOANE DIN MEDIU URBAN ŞI RURAL DIN JUDEŢUL BACĂU

Cecilia Lucaci
Doctorand al Universităţii de Medicină şi Farmacie "Gr.T. Popa" Iaşi
Direcţia de Sănătate Publică Bacău

BIOCHEMICAL STATUS ASSESSMENT IN 464 PERSONS FORM BACĂU COUNTY (Abstract) : The purpose of the study was to assess the biochemical status in a populational lot of 464 persons from Bacău County (urban and rural), through a minimal set of laboratory tests (glycemia, cholesterol, HDL-cholesterol, triglyceride). **Results** : The average values from the rural lot are closed to the minimal limits of the values interval. The highest values (peaks) of glycemia in the rural lot are in the over 65 y.o. group, followed by great values registered in the 41-65 y.o. group. For the urban lot, the highest value is in the 41-65 y.o. group, that might be explained by the etiopathogenesis role of stress in the diabetes at young ages. Also, comparing the peaks in these two lots (rural vs. urban), we can notice that in the rural lot, the peaks are much higher than in the urban lot. A possible explanation might be a tighter monitoring of diabetes in urban vs. rural or a proper diet and lifestyle behavior in the urban lot.The averages values of cholesterol in the rural lot, for all groups of ages, are below the maximal admitted value (220 mg/dL) and the peaks are in the 41-65 y.o. group and over 65 y.o., while in the urban lot the peaks are in the over 65 y.o. group. The minimal values of HDL cholesterol fraction which are inverse correlated with the risk of cardiovascular diseases emergence, are found in the extreme ages groups : 20-40 y.o. and over 65 y.o. In the urban lot, the average values for the three age groups are closed and shows a low risk of cardiovascular diseases emergence (values up to 55 mg/dL). Regarding the levels of triglycerides, even if are below the maximal admitted values, in the rural lot, the peaks values are dispersed and are very high in the extreme ages groups : 20-40 y.o. and over 65 y.o., while in the urban lot peaks values are in the 41-65 y.o. group. **Key words** : BIOCHEMICAL STATUS, MAXIMAL ADMITTED VALUE, AVERAGE VALUE

MONOCLONAL ANTIBODIES – PAST, PRESENT AND FUTURE

MONOCLONAL ANTIBODIES – PAST, PRESENT AND FUTURE (Abstract): Monoclonal antibodies (mAbs) are monovalent antibodies, produced artificially from a single B-lymphocyte clone. They have a higher specificity binding to the same epitope. The mAbs era started in 1975 with the monoclonal antibody technique. This field is rapidly growing, around 60 therapeutic monoclonal antibodies being now available on the market for organ transplantation or to treat several diseases. Over the years, the technological developments and improvements have generated chimeric, humanized and human mAbs. Reopro (Abciximab) was approved in 1994 as the first chimeric mAb for the prevention of blood clots, Zenapax (Daclizumab) was approved in 1997 as the first humanized mAb to diminish kidney transplant rejection, Humira (Adalimumab) was approved as the first human mAb obtained through phage display library in 2002 for the treatment of rheumatoid arthritis, and Vectibix (Panitumumab) was approved as the first human mAb obtained through transgenic mouse technology in 2006 for the treatment of colorectal cancer. The present commercial success of mAbs is due to the new technological achievement which allowed lower administration costs, greater clinical efficacy and lower side effects. A series of fundamental technologies enabled the development of monoclonal antibodies derivatives such as: antibody fragments, bispecific antibodies, antibody drug conjugates, fusion proteins. All the technological and scientific acquisitions over the last years have made mAbs available to an ever-increasing number of patients for whom the quality of lives has improved. **Keywords:** MONOCLONAL ANTIBODIES, MABs, HYBRIDOMA TECHNIQUE, PHAGE DISPLAY TECHNOLOGY.

The idea that an antibody can target like a "magic bullet" only one specific antigen was and still is considered a major scientific breakthrough, of tremendous therapeutic value.

Monoclonal antibodies (mAbs) are antibodies produced artificially, with a higher specificity, from a single B-lymphocyte clone. They are monovalent antibodies, which bind to the same epitope.

The mAbs era started in 1975 with the monoclonal antibody technique, created by Georges Köhler, César Milstein and Niels Kaj Jerne by using mouse x mouse hybrid-

oma. Further, in 1984 they received the Nobel Prize in Physiology or Medicine for this discovery.

In 1986 (11 years later), the US Food and Drug Administration (FDA) approved the first therapeutic monoclonal antibody, Muromonab-CD3 (Orthoclone OKT3) to prevent the rejection of transplanted kidneys. By 2017, FDA has approved around 60 therapeutic mAbs (1, 2). In 2015 FDA approved 10 new therapeutic monoclonal antibodies, being the historical high since first approval (3).

All monoclonal antibodies currently approved by the regulatory authorities such as Food and Drug Administration (FDA) or European Medicines Agency (EMEA) are used in humans for treating various diseases such as: cancer, chronic inflammatory diseases, infectious diseases, autoimmune diseases and cardiovascular diseases or in organ transplantation. For these diseases mAbs have revolutionized treatment practices and also improved patient quality of life.

The mAbs field is rapidly growing, humanized and human monoclonal antibodies being now the fastest growing group of biotechnology-derived molecules in clinical trials. The global value of the monoclonal antibodies market is approximately $20 billion per year, with an expected annual rate of growth of 15% (4, 5).

The lack of early mAbs commercial success was due to the high costs of its administration; therefore, in order to become more commercially viable, greater clinical efficacy and fewer side-effects are still needed for monoclonal antibodies.

Antibody structure

Antibodies are Y-shaped molecules belonging to five major classes of immunoglobulin (Ig): IgA, IgD, IgE, IgG, and IgM. The IgG class forms the framework for the development of therapeutic antibodies.

The antibody molecule has two identical light (L) chains and two identical heavy (H) chains, held together by hydrogen bonds and disulfide linkages (fig. 1) (6).

The first sequence of both chains form the variable domain (V_H and V_L), each of them containing hypervariable sequences, known as complementarity determining regions (CDRs). The remaining amino-acid sequences of each light chain form the constant domain (C_L), and the remaining sequences of each heavy chain form the constant domain (C_{H1}, C_{H2}, C_{H3}). The variable regions are the antigen-binding regions via CDRs and the constant regions are responsible for effector recognition and binding (6).

The antibody molecule can be cleaved by proteolytic digestion into different fragments: Fab (antigen binding fragment), Fc (crystallizable fragment) and Fv (variable fragment).

The amino-acid sequences from the constant regions of each heavy chain found in the Fc fragment are the same in individuals within the same species but different among the species.

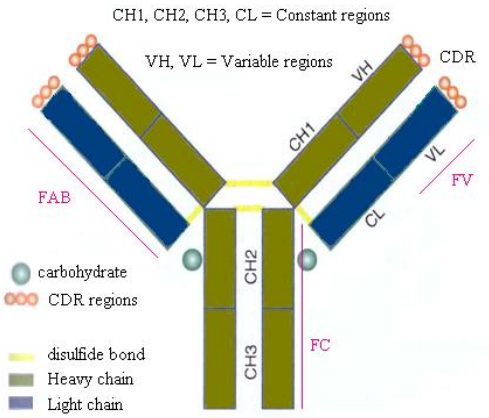

Fig. 1. Antibody structure

Monoclonal antibody technologies

A series of fundamental technologies allowed the development of monoclonal antibodies and its derivatives such as: antibody fragments, bispecific antibodies, antibody drug conjugates, fusion proteins etc.

The hybridoma technique created the first monoclonal antibody approved for therapeutic use in 1986, Orthoclone-OKT3 (muromonab), a fully murine antibody, used in preventing kidney transplant rejection. This technique involves the obtaining of B-lymphocytes from the spleen of an immunized animal fused then with an immortal myeloma cell line in order to obtain hybridoma cells that are cultured *in vitro* in selective medium (6).

Muromonab is rarely used due to its side-effects (human anti-mouse antibody response-HAMA), which explain the lack of initial clinical and commercial success of monoclonal antibodies.

The technical difficulties in large scale production, the high production costs, low yields, together with poor penetration in solid tumors, potential viral safety problems, the mAbs short half-life, the HAMA response led to technological developments and improvements. All these improvements embodied in strategies to generate chimeric, humanized and human mAbs (fig. 2) (6).

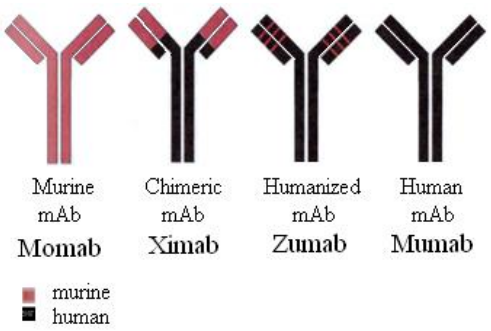

Fig. 2. Generations of therapeutic mAbs

Chimeric antibodies can be obtained by depletion of amino-acid sequence from the constant region of mouse antibody and replacing it with an amino-acid sequence of the Fc region of a sequence. Chimeric antibodies have a constant part from human peptide sequences, but the variable part of the Fab fragments contains mouse protein. Reopro (Abciximab) was approved as the first chimeric mAb in 1994 for prevention of blood clots in angioplasty. Abciximab is originally produced in mammalian cell cultures as chimeric antibody and then cleaved enzymatically (6, 7).

Chimeric antibodies are about 70% human. The specific action of the chimeric antibody is identical to that of the murine antibody, but the *in vivo* half-life and other pharmacokinetic functions are human, being determined by the Fc fragment. Unfortunately, there is an important immune response less likely than murine antibodies.

Humanized antibodies are about 95% human. These mAbs are largely human except for the hypervariable sequences (CDR) which is still of murine origin. The technologies for antibody humanization became available during the mid-1980s and are continuously improved. During the 1990s and 2000s several humanization methods such as CDR grafting, resurfacing, super humanization, human string content optimization, phage, ribosome or yeast display have been developed in order to achieve full biocompatibility (7).

Zenapax (Daclizumab) was approved in 1997 as the first humanized mAb to diminish kidney transplant rejection. Daclizumab was generated by selecting human framework regions to maximize resemblance to the murine antibody sequence.

Human antibodies are 100% human and fully biocompatible. In order to obtain

these mAbs several technologies such as phage display and transgenic mice technology are available.

Humira (Adalimumab), the first human mAb obtained through phage display library, reached the market in 2002 for the treatment of rheumatoid arthritis and Crohn's diseases. The entire technology is done *in vitro* and involves the isolation of mRNA from human B-lymphocytes in order to amplify all the V_H and V_L regions via PCR, followed by the insertion of the genes into M13 bacteriophage vector in order to transfect *E. coli* to generate a large phage library of antibodies. Each phage exposes a protein and its encoding DNA which occurred jointly on its surface (7).

Vectibix (Panitumumab), the first human mAb obtained through transgenic mouse technology reached the market in 2006 for the treatment of colorectal cancer. The technology implies the replacement of the endogenous murine IgG genes with human IgG genes in transgenic mice (XenoMouse® - Abgenix, Inc., Fremont, CA), hence mouse B-lymphocytes will synthesize human antibodies and hybridomas can be produced (6, 7).

About 60 mAbs are approved by the FDA or EMEA for therapeutic use and are now marketed, as shown in Table I.

TABLE I

Therapeutic monoclonal antibodies approved in the European Union or United States

International Common Denomination (ICD)	Trade name	Characteristics	Therapeutic indication	Approval year
Muromonab-CD3	Orthoclone OKT3	Murine IgG2a	Allograft rejection	1986
Abciximab	Reopro	Chimeric IgG1 Fab	Prevention of blood clots in angioplasty	1994
Rituximab	MabThera, Rituxan	Chimeric IgG1	Non-Hodgkin's lymphoma	1997
Basiliximab	Simulect	Chimeric IgG1	Prevention of kidney transplant rejection	1998
Palivizumab	Synagis	Humanized IgG1	Prevention of RSV infection	1998
Infliximab	Remicade	Chimeric IgG1	Crohn disease	1998
Trastuzumab	Herceptin	Humanized IgG1	Breast cancer	1998
Adalimumab	Humira	Human IgG1	Rheumatoid arthritis	2002
Ibritumomab tiuxetan	Zevalin	Murine IgG1	Non-Hodgkin lymphoma	2002
Omalizumab	Xolair	Humanized IgG1	Asthma	2003
Cetuximab	Erbitux	Chimeric IgG1	Colorectal cancer	2004
Bevacizumab	Avastin	Humanized IgG1	Colorectal cancer	2004
Natalizumab	Tysabri	Humanized IgG4	Multiple sclerosis	2004
Tocilizumab	Actemra	Humanized IgG1	Castleman disease	2005
Ranibizumab	Lucentis	Humanized IgG1 Fab	Macular degeneration	2006
Panitumumab	Vectibix	Human IgG2	Colorectal cancer	2006
Eculizumab	Soliris	Humanized IgG2/4	Paroxysmal nocturnal	2007

International Common Denomination (ICD)	Trade name	Characteristics	Therapeutic indication	Approval year
			hemoglobinuria	
Certolizumab pegol	Cimzia	Humanized Fab Pegylated	Crohn disease	2008
Golimumab	Simponi	Human IgG1	Rheumatoid and psoriatic arthritis, Ankylosing spondylitis	2009
Canakinumab	Ilaris	Human IgG1	Muckle-Wells syndrome	2009
Ustekinumab	Stelara	Human IgG1	Psoriasis	2009
Tocilizumab	RoActemra	Humanized IgG1	Rheumatoid arthritis	2009
Ofatumumab	Arzerra	Human IgG1	Chronic lymphocytic leukemia	2009
Denosumab	Prolia	Human IgG2	Bone loss	2010
Belimumab	Benlysta	Human IgG1	Systemic lupus erythematosus	2011
Ipilimumab	Yervoy	Human IgG1	Metastatic melanoma	2011
Brentuximab vedotin	Adcetris	Chimeric IgG1	Hodgkin lymphoma	2011
Pertuzumab	Perjeta	Humanized IgG1	Breast cancer	2012
Mogamulizumab	Poteligeo	Humanized IgG1	T cell leukemia-lymphoma	2012
Trastuzumab emtansine	Kadcyla	Humanized IgG1	Breast cancer	2013
Obinutuzumab	Gazyva	Humanized IgG1	Chronic lymphocytic leukemia	2013
Alemtuzumab	Lemtrada	Humanized IgG1	Multiple sclerosis	2013
Vedolizumab	Entyvio	Humanized IgG1	Crohn disease, Ulcerative colitis	2014
Ramucirumab	Cyramza	Human IgG1	Gastric cancer	2014
Pembrolizumab	Keytruda	Human IgG4	Metastatic melanoma	2014
Siltuximab	Sylvant	Chimeric IgG1	Castleman disease	2014
Nivolumab	Opdivo	Human IgG4	Malignant melanoma	2015
Secukinumab	Cosentyx	Human IgG1	Psoriasis	2015
Dinutuximab	Unituxin	Chimeric IgG1	Neuroblastoma	2015
Alirocumab	Praluent	Human IgG1	Hypercholesterolemia	2015
Idarucizumab	Praxbind	Humanized Fab	Reversal of dabigatran-induced anticoagulation	2015
Evolocumab	Repatha	Human IgG2	Hypercholesterolemia	2015
Daratumumab	Darzalex	Human IgG1	Multiple myeloma	2015
Mepolizumab	Nucala	Humanized IgG1	Severe asthma	2015
Necitumumab	Portrazza	Human IgG1	Metastatic melanoma	2015
Elotuzumab	Empliciti	Humanized IgG1	Multiple myeloma	2015
Obiltoxaximab	Anthim	Chimeric IgG1	Anthrax infection	2016
Ixekizumab	Taltz	Humanized IgG4	Psoriasis	2016
Reslizumab	Cinqair	Humanized IgG4	Severe asthma	2016

International Common Denomination (ICD)	Trade name	Characteristics	Therapeutic indication	Approval year
Daclizumab	Zinbryta	Humanized IgG1	Multiple sclerosis	2016
Adalimumab-Atto	Amjevita	Human IgG1	Rheumatoid arthritis, Ankylosing spondylitis, Psoriasis, Crohn disease	2016
Atezolizumab	Tecentriq	Humanized IgG1	Urothelial carcinoma	2016
Olaratumab	Lartruvo	Human IgG1	Soft tissue sarcoma	2016
Bezlotoxumab	Zinplava	Human IgG1	Reduce recurrence of *Clostridium difficile* infection	2016
Brodalumab	Siliq	Human IgG2	Psoriasis	2017
Sarilumab	Kevzara	Human IgG1	Rheumatoid arthritis	2017
Ocrelizumab	Ocrevus	Humanized IgG1	Multiple sclerosis	2017
Dupilumab	Dupixent	Human IG4	Severe atopic dermatitis	2017
Durvalumab	Imfinzi	Human IgG1	Urothelial carcinoma	2017
Avelumab	Bavencio	Human IgG1	Merkel cell carcinoma	2017

Production of mAbs at industrial level

The clinical and commercial success of monoclonal antibodies has led to the need of developing strategies to translate small-scale production into large-scale production.

An industrial production process involves the obtaining of a mAb (through immunization of an animal or by molecular biology methods), the identification of the coding DNA sequence and the construction of a clone which is further cultivated. All these steps require about 1-2 years. Commercial production of mAbs usually uses different expression systems such as mammalian cells of mouse (type NS0 or SP2/0 cell lines), Chinese hamster ovary (CHO cell line) and prokaryote (*Escherichia coli*, only in the production of mAbs fragments) (5).

Recently, many other different expression systems for monoclonal antibodies have been tested, such as human embryonic retina cells (Per.C6®), avian EBx cell line, rat myeloma YB2/0 cell line, transgenic animals, transgenic plants (*Nicotiana tabacum*) (5).

For mammalian cell cultivation are used highly complex media (which contain, among others, amino-acids, trace elements, vitamins, nucleosides etc), the production processes being carried out in stainless-steel stirred-tank bioreactors, working volume ranges from 1000 to 25000 L. The cultivation process usually takes place at 37^0C, pH 7.15, 30-60% dissolved oxygen levels for 12-14 days of culture (5).

Today large-scale production processes enable mAbs yields of 3-5 g/L, some companies reaching up to 10-13 g/L of mAbs in fed-batch processes or up to 25 g/L via modified perfusion processes (8).

Future perspective

Nowadays, many of monoclonal antibody therapeutic candidates (more than 200) are in clinical trials at different companies. The present commercial success of mAbs is due to the new technological achievement which allowed lower administration cost, greater clinical efficacy and lower side-effects.

Various optimization strategies can be used to improve the effector functions of

mAbs. IgG1, IgG4 and IgG2 antibody isotype were engineered to reduce instability of the mAbs and to reduce the binding properties to cellular Fc receptors (4). Glycoengineered antibodies obtained by engineering of the glycosylation profile can enhance the antibody-dependent cellular cytotoxicity (ADCC) activity (9). As well, the modification of the protein backbone of mAbs can enhance or reduce the binding properties to Fc receptors.

Immunoconjugates and bispecific antibodies are some of the promising methodological approaches. The use of antibody drug conjugates (a toxin, a chemotherapeutic agent, a radioactive isotope linked to a mAb) allows a specific tumor targeting of mAbs and provide highly potent drugs (4, 10). Also, the use of the bispecific antibodies, generated by genetic engineering techniques, enable simultaneous targeting of two distinct target antigens, likewise the delivery of mAbs into the brain in order to increase brain penetration (4, 10).

Even if the discovery and development of therapeutic mAbs is a very elaborate process, there is a great interest from scientists to improve clinical efficacy and to discover additional effects for mAbs.

CONCLUSIONS

Our study revealed that monoclonal antibodies, due to their specificity and flexibility, are an attractive therapeutic class to be watched in the future.

There is a major interest from pharmaceutical companies to develop monoclonal antibodies for clinical use though the commercial production of mAbs is a lengthy process, complex from technical point of view and a resource consuming one.

All the technological and scientific acquisitions over the last few years have made mAbs available to an ever-increasing number of patients for whom the quality of lives has improved.

EVALUATION OF THE INFLUENCE OF LOCAL ADMINISTRATION OF VITAMIN D ON THE RATE OF ORTHODONTIC TOOTH MOVEMENT (Abstract): Accelerated orthodontic tooth movement is currently the subject of numerous scientific studies that aimed to improve the duration of orthodontic treatment. Several approaches had been performed in order to reduce the period in which a patient is subjected to orthodontic treatment. This are biological, surgical and physical approaches. **Aim:** This study has two purposes: first to assess the influence of local administration of vitamin D3 on orthodontic tooth movement and second to evaluate if there is any secondary effect of locally administration of vitamin D3 on dental roots. **Material and methods:** Every dental arch has been divided in two: one control quadrant and one experimental quadrant. The control canine received only conventional orthodontic treatment in comparison with the experimental canine who benefited from the association between orthodontic therapy and intraligamentary administration of vitamin D3. **Results:** 6 dental arches were studied. The average rate of tooth movement was greater in experimental canines compared to control canines. We recorded an average of 70 % more tooth movement for the experimental teeth compared to control ones. The differences between the two quadrants (control and experimental) are statistically significant. **Conclusions:** Locally administration of vitamin D3 seemed to increase the rate of orthodontic tooth movement. No root resorption was found three months after the first administration of vitamin D3 evaluated on cone-beam CT exam (cone-beam computed tomography). **Keywords:** ACCELERATED ORTHODONTIC TOOTH MOVEMENT, BONE TURNOVER, VITAMIN D, BONE REMODELLING.

Accelerated orthodontic tooth movement is currently the subject of numerous scientific studies that aimed to improve the duration of orthodontic treatment. Several approaches had been performed in order to reduce the period in which a pa-

tient is subjected to orthodontic treatment. Based on scientific data available in literature, there are mainly three approaches, which associated with conventional orthodontic treatment, reduce the treatment period and increase the rate of tooth movement: biological, physical and surgical approaches (1, 2, 3).

Given the magnitude of mechanical force applied to a tooth in order to obtain tooth movement, Schwarz is the one who defined the "optimal orthodontic force" concept (4). According to this, the force is optimal when it entails a tissue pressure approximately equal to periodontal ligament capillaries blood pressure, allowing blood flow in the periodontal ligament. The forces below this level do not cause any dental movement, whereas the forces above the optimal value lead to areas of cellular necrosis because of creating avascular areas.

Several researchers have shown their interest in optimizing the response of periodontal tissues during orthodontic treatment while maintaining on optimum level of mechanical forces. The physical, biological and surgical approaches have in common the fact that they increase or stimulate the biological mechanisms responsible for the regeneration of bone around the tooth (1, 2, 5).

Surgical approaches (osteotomy, cortectomy, surgical reduction of the interseptal bone, piezoincision) associated to orthodontic treatment in order to optimize its duration, is based on the principle according to which the bone turnover is accelerated in the fractures and osteotomies (1, 5, 6, 7). The "accelerating regional phenomenon" was particularly attributed to surgical induced regeneration of the bone in case of cortectomies created in association with orthodontic treatment in order to enhance the rate of orthodontic tooth movement (1,5-7).

Given the role of cytokines, parathyroid hormone, active vitamin D3 (1,25 dihydroxycholecalciferol) in bone regeneration, several studies have been conducted in which exogenous biological molecules have been locally administrated in order to stimulate orthodontic tooth movement (8-12). Vitamin D3 intraligamentary administered increased the rate of dental movement in mice when canine bilateral distalization was performed using low forces (11).

The studies on the effect of intraligamentary administration of vitamin D3 on the dental movement performed in human beings are few and inconclusive.

This study has two purposes: first to assess the influence of local administration of vitamin D3 (1.25 dihydroxycholecalciferol) on orthodontic tooth movement and second to evaluate if there is any secondary effect on dental roots after intra-ligamentary administration of vitamin D3.

MATERIAL AND METHODS

Patients were selected based on the following **inclusion criteria:**

- Presence of abnormal teeth alignment that requires bilateral extractions of the first premolars;
- Need of bilateral distalization of the maxillary or mandibular canines;
- General good health;
- Absence of chronic disorders or chronic drug intake;
- No history of orthodontic treatment;
- Presence of vital teeth, with healthy periodontium, without root resorption.

After patients' selection, a written consent for participation in the study was submitted. Only four patients agreed and were included in the study.

Six arches (four maxillary and two mandibular) were studied. Three patients were diagnosed with malocclusion and space deficit, requiring extractions of the four first premolars and one of the patients was diagnosed with bilateral anodontia of the lateral incisor, requiring the distalization of the canines (tab. I).

TABLE I
Illustration of patients' data.

	Age	Sex	Arch	Diagnostic	Duration of alignment and levelling (months)	Dental movement (mm)		
						Control canine	Experimental canine	Difference
1	18	M	Maxillary	DDM	4	1.40	2.40	1.00
2	34	F	Maxillary	Anodontia IL	5	0.00	1.20	1.20
3	15	M	Maxillary	DDM	3	1.01	1.40	0.39
4	15	M	Mandible	DDM	2	1.00	1.21	0.21
5	13	F	Maxillary	DDM	2	1.80	2.60	0.80
6	13	F	Mandible	DDM	3	0.80	1.39	0.59
Average	**18**				**3.17**	**1.00**	**1.70**	**0.70 mm**

After diagnostic and treatment plan recording (performing clinical and paraclinically examinations: intra-oral pictures, study model, panoramic x-ray, profile radiographic cephalometric), fixed orthodontic appliance was fitted. (Roth 0.22). All patients received instructions regarding good oral hygiene. It was prohibited to take drugs during the follow-up period. In case of pain associated to dental movement, only the administration of paracetamol was allowed. According to the treatment plan, extractions of the first premolars were performed after the trans palatal arch positioning. Seven days after, the fixed orthodontic appliance was applied to all teeth. The maxillary and mandibular arch was divided in two quadrants: one control and on experimental quadrant. Canine distalization was achieved using a closed Niti spring of 12 mm which generated a force of 150gm (TruFlex™ NiTi Closed Coil Springs, 12 mm, 150 gm Medium, Ortho Technology, Tampa, Florida, USA).The distalization force for each canine was measured using a dynamometer (Falcon Medical, Italy). Experimental canines benefitted from intra-ligamentary administration of vitamin D3 (Decostriol®, Mibe Jena, Germany). The vector for the administration of vitamin D3 was dymethylsulphoxyde, lip soluble solvent (DMSO, Milan, Italy). An amount of 0.2 mL of vitamin D3 (42 pg/mL) was administered, once a week, three weeks. Three cone-beam CT examinations were carried out for each patient: before the canine distalization, one month after and three months after the first administration of vitamin D3. Intra-oral pictures were also taken on a monthly basis and every week during the follow-up period.

Dental movement was measured on CBCT (Planmeca Romexis Viewer v 3.2.7). A conventional axial plane passing from the enamel-cement junction of the second premolars was identified in order to perform required measurements (fig. 1). On this axial plane, a conventional horizontal line passing through the middle of the pulp chamber of the second right premolar was used as reference to measure the sagittal

positions of the control and experimental canines one month before and after the distalization treatment (fig. 1). The difference between the initial measurements and the measurements made one month after indicates the amount of tooth movement. Clinical aspects of maxillary arch of a patient are shown in figure 2.

Secondary effect on the root of the canines (cement resorption) was evaluated on cone-beam CT 3 months after the first administration analyzing the axial, transversal and sagittal sections of each tooth included in the study.

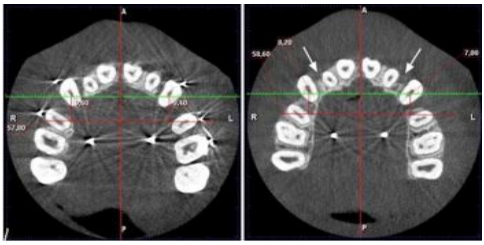

Fig. 1. Cone-beam CT of the maxillary arch.

Fig. 2. Clinical picture of the patient's maxillary arch.

Dental movement was analyzed by comparing the averages using the test Wilconson-Mann Whitney. A difference of a $p<0.05$ was considered statistically significant. The study protocol was approved by the Committee of Ethics and Research within our university.

RESULTS

On the average, the treatment with vitamin D3 induces a dental movement which is higher by 0.70 mm to control tooth (table I). Dental movement is 1.70 mm for test group and 1.00mm for control group (tab. I). In percentages, this means a dental movement 70% higher in the experimental group.

The parametric test Wilcoxon-Mann Whitney suggests there is no significant statistical difference between the group of men and that of women (table II). On the average, dental movement is more important at maxillary arch compared to mandible. It is 1.90 mm at maxillary, against 1.30 mm for the mandible (tab. II). However, the Wilcoxon-Mann-Whitney test shows that this difference does not testify a difference statistically significant in the two groups. Dental movement does not seem associated to the duration of the alignment (tab. II). Therefore, the movement within the treated group is 1.91 mm for an alignment period of 2 months, and 2.40 mm for an alignment period of 4 months, whereas it is 1.40 mm for a period of 3 months and 1.20 mm for an alignment period of 5 months. The Wilcoxon test on the dental movement differences between the two groups, test and control suggests that dental movement is systematically more important in the test group in relation to the control groups. It could be noted that the test of the Wilcoxon ranges shows the fact that the results are statistically significant, suggesting the existence of a distribution statistically significant in the two groups (p-value=0.0313). The differences between the two groups are statistically significant and could lead to the conclusion that an intra-ligamentary administration of the vitamin D3 seemed to increase the rate of tooth movement. In addition, no root resorption was observed three months after the first injection of vitamin D3.

TABLE II.

Perspective on the sex influence, dental arch of interest and duration of alignment and levelling for the dental movement of the control and experimental teeth: *Test statistically impossible because of an insufficient batch (only one arch studied for an alignment period of 4 and 5 months).

			Average	Type of distance	Minimum	Maximum	p value

DISCUSSION

Vitamin D3 was mentioned in literature as the most important bio-modulator of bone tissue (8,13) which justifies our study to assess its role on the rate of orthodontic tooth movement in human beings. Collins and Sinclair reported a 60% increase of the rate of orthodontic tooth movement in experimental animals after intra-ligamentary administration of vitamin D3 (11). This is explained by the effect of vitamin D3 on osteoclasts cells (13).

Intra-ligamentary administration was selected given the effect of vitamin D3 on bone tissue metabolism (11) at a physiological dosage (15). The reference blood value of vitamin D3 is 30-80 pg/mL. A lower quantity (0.2 mL) of vitamin D3 administered by intra-ligamentary path was performed in accordance with Malamed instructions: administration of a low quantity of substances using low pressure to limit the pain of the patient (16,17). According to the data existing in literature, the optimal orthodontic pressure to move maxillary canine is 150-260 cN (152.9-261.01 gm) and 150-200 cN (152.9-203.874 gm) for mandibular canine (18).

Dental movement measures were made on CBCT in order to observe 3D movements of the roots, not only those of the dental crown. Moreover, cone beam CT examination have proven to be very effective in identifying initial root resorptions (19,20,21). In this study, no root resorption was observed three months after the first administration of vitamin D3. For the first time, this study brings information about the effect of vitamin D3 on the roots during a follow-up period of three months by using the 3D scanner.

CONCLUSIONS

Exogenous administration of active vitamin D3 seems to be involved in stimulating orthodontic tooth movement. Three months after local administration of vitamin D3 no root resorption was observed.

ALCOHOL CONSUMPTION WITH FAMILY PATTERN RELATED TO STRONG PERSONALITIES: A CASE-CONTROL STUDY OF ROMANIAN MARRIED STUDENTS (Abstract): In the study conducted the aim was to investigate strong personalities (SP) related to alcohol consumption in married students from Romania. **Material of study** consisted in 2 samples: a case-sample (23 alcohol consumer students with a family pattern of weekly consumption, 47.8% male and 52.2% female, aged 21-29 years) and a control-sample (42 no-alcohol consumer students without a family pattern of consumption, 26.2% male and 73.8% female, aged 21-29 years), selected from a sample of 176 married students. **Method**: an observational inquiry (case-control) consisted in applying 2 questionnaires: Health Questionnaire (60 items, 7: Q43-Q49 -alcohol consumption) and Strong Personalities Questionnaire (88 items, alpha-Crohnbach index-0.823). Statistical analysis was performed by the aid of SPSS 20 Program. **Results**: For alcohol consumer students with weekly pattern of consumption the main reason of alcohol consumption was curiosity (60.9%) and the most frequent consumed alcohol was beer (38.6%, 500-3000 ml/week). Personalities` profiles revealed V-hyperthymic, III-hyperperseverant and X-emotive strong personalities (SP) as being symptomatic (over 50% symptomatic level-SL) for both samples, with a difference (control-case) for X-emotive SP (71.7% students – 57.1% students, respectively). I-demonstrative, VII-cyclothymic and IV-unruly SP presented a difference between case (symptomatic: 61.8%; 61.8% and 61.8% students, respectively) and control (symptomatic: 36.8%; 37.5% and 45% students, respectively) samples. A statistically significant difference case-control samples was demonstrated for I-Demonstrative (item S29: chi square χ^2=10.65; Sig.0.002; gamma correlation γ=0.73; Sig.0.002) and for X-emotive (item S25: χ^2=8.76; γ=-0.66; Sig.0.003) SP. In **conclusion**, a relation SP-alcohol consumption in married students is suggested.
Keywords: ALCOHOL CONSUMPTION, PERSONALITY, MARRIED STUDENTS.

Alcohol consumption continues to be a risk behavior of young people in Romania (1) and Europe (2). Alcohol culture and family structure were demonstrated as important predictors for alcohol consumption (3). Personality structure could be a condition for alcohol consumption behavior that could determine a psychological outcome (4). In this study I aimed to investigate strong personalities of young married students related to their alcohol consumption behavior and their family pattern of alcohol consumption.

MATERIAL AND METHODS

This study was performed on two samples: a case-sample (23 alcohol consumer students with family pattern of weekly consumption, 47.8% male and 52.2% female, aged 21-29 years – 91.2%) and a control-sample (42 no-alcohol consumers with no family pattern of consumption, 26.2% male and 73.8% female, aged 21-29 years – 90.4%). The two samples were selected from 176 married students (31.2% male and 68.8% female, aged 19-30 years).

The method - an observational inquiry (case-control) applying 2 questionnaires: Health Questionnaire (60 items, 7: Q43-Q49 - alcohol consumption) and Strong Personalities Questionnaire (SPQ-88 items, Crohnbach`s alpha index = 0,823) (5). The Q43-Q49 items assess: reason, frequency, relation to sexual inhibitions, to school/work difficulties, type and quantity, social environment and family pattern of alcohol consumption. Ten strong personalities (SP) are highlighted by SPQ: I-demonstrative, II–hyperexact, III-hyperperseverant, IV–unruly, V–hyperthymic, VI–dysthymic, VII-cyclothymic, VIII–exalted, IX–anxious, X-emotive. The application of both questionnaires was: individual, anonymous, 1 hour and a half long; and asking for free written consent. Statistical analysis (chi square-χ^2 and gamma correlation-γ) was performed by SPSS 20 Program.

RESULTS

In the case-sample: reasons of **alcohol consumption** were curiosity (60.9%) and releasing themselves from emotional and sexual inhibitions (43.5%); alcohol consumers with weekly pattern of consumption consumed alcohol 3-5 times/week (100%); they consumed 500-3000 ml beer/week (38.6%),200-1000 ml wine/week (30.4%) and 50-500 ml vodka/week (17.3%); they drank alcohol with a group of friends (52.2%) and with the family (26.1%).

A comparative analysis of SP between case (A) and control (B) samples demonstrated 3 SP at high symptomatic level (SL) for both samples: X-emotive, V-hyperthymic and III-hyperperseverant (tab. I, II). A difference case-control samples regarding SL was registered for 3 SP: **I-demonstrative** at SL 58.1% (33.3% students–A) and at SL 41.5% (23.6% students-B), **IV-unruly** at SL 62.5% (28.5% students-A) and at SL 50% (17.5% students–B) and **IX-anxious** at SL 75% (23.5% students-A) and at SL 37.5% (24.3% students-B) (tab. I, II). An analysis of **total symptoms over 50%** SL presence for each SP demonstrated the 3 mentioned SP with high students` frequency at high SL as being symptomatic for both samples: **V-hyperthymic** (71.4% students-A / 67.5% students-B), **III-hyperpeseverant** (71.39% students-A / 56.41% students-B) and **X-emotive** (71.7% students-B / 57.1% students-A). **I-demonstrative** (61.89% students-A / 36.83 students-B) and **IV-unruly** (61.8% students-A / 45% students-B) maintained the difference between the 2 case-control samples. **VII-Cyclothymic** SP registered a difference of total symptoms presence over 50% between case (61.8% students) and control (37.5% students) samples (tab. I, II). SP profiles (fig.1) present comparatively for case-control samples the mentioned aspects.

A statistically significant difference case-control samples was demonstrated for I-demonstrative (S29: χ^2=10.65; Sig.0.002; γ=0.73; Sig.0.002) and X-emotive (S25: χ^2=8.76; Sig.0.004; γ=-0.66; Sig.0.003) SP.

DISCUSSION

Novelty seeking (curiosity) and decrease of sexual inhibitions relate to later positive reinforcement of alcohol drinking motives in the literature (6) and they are the main reasons for alcohol consumption in the conducted study. Strong personalities` profiles are more symptomatic in case (I-demonstrative, IV-unruly and VII-cyclothymic) than in control samples (where X-emotive SP is more symptomatic). In the research literature, weekly alcohol consumption behavior relates to: responsibility and impulsivity among males (7), different levels of self-esteem in men and women (8), extraversion in weekend consumption and low agreeableness in weekday alcohol use (9). In the performed study I-demonstrative and X-emotive SP relate significantly to alcohol consumption pattern. Reduced emotional stress of married alcohol consumers is demonstrated in this study through X-emotive nature in SP profiles and it also sustains disinhibition as a later positive reinforcement drinking motive (6). A limit of this study is that it is an observational one.

CONCLUSIONS

A relation of strong personalities to alcohol consumption with weekly family pattern in married students is suggested.

NEWS

ANGIOGENESIS IN BREAST CANCER AND ITS CORRELATION WITH ESTROGEN, PROGESTERONE RECEPTORS AND OTHER PROGNOSTIC FACTORS

There has been global increase in incidence of breast cancer over the last several decades in Asian countries than in United States and Europe. A prognostic factor is any measurement available at the time of surgery that correlates with disease-free or overall survival in the absence of systemic adjuvant therapy and, as a result, is able to correlate with the natural history of the disease. In contrast, a predictive factor is any measurement associated with response to a given therapy. Lymph node status, Tumour size, Lymphovascular invasion, Proliferation markers, Ethnicity, and Age are the prognostic factors while ER/PR status, HER2/neu, Urokinase-type plasminogen activator (uPA) and its inhibitor, plasminogen activator inhibitor type 1 (PAI-1), Genetic profiling are prognostic as well as predictive factor. Angiogenesis is required for invasive tumour growth, metastasis; and constitutes an important role in the control of cancer progression. Its inhibition may be a valuable new approach to cancer therapy. Angiogenesis provide increased availability of oxygen and nutrients to the tumour as well as the most important route of exit from the primary tumour into the blood stream. Assessment of intratumoural microvessel density using immunohistochemistry with panendothelial markers like factor VIII–related antigen, CD31, CD34, and the activated endothelial cell marker CD105 is a commonly used technique for quantifying tumour angiogenesis in breast cancer. The presence of estrogen and progesterone receptors in an invasive breast carcinoma is both prognostic and predictive. Its prognostic effect is difficult to evaluate in that it must be assessed in the absence of adjuvant tamoxifen. In the era of targeted therapy, some authors use antiangiogenic therapy to reduce the tumour progression and tumour metastasis. The most important clinical implication of tumour angiogenesis is the development of a novel strategy of anticancer therapy targeting tumour vessels instead of cancer cells. Antiangiogenic therapy aims to inhibit the growth of tumour, and current evidence suggests that it works best in combination with conventional cytotoxic chemotherapy. Evaluation of estrogen and progesterone receptors status is a routine procedure in the management of breast cancer. Receptor status is useful not only for defining prognosis in breast cancer but also for selection of patients for therapy. In conclusion, the information about prognostic factors in breast cancer patients may lead to better ways to identify those patients at high risk who might benefit from adjuvant therapies (Bharti JN, Rani P, Kamal V, et al. Angiogenesis in Breast Cancer and its Correlation with Estrogen, Progesterone Receptors and other Prognostic Factors. Journal of Clinical and Diagnostic Research. 2015, Vol-9(1): 5-7).

SEXUALITY, BODY IMAGE AND PSYCHOLOGICAL WELL-BEING IN OF PATIENTS WITH MASTECTOMY AFTER BREAST CANCER (Abstract). **The aim** of the study is to identify the factors which influence the psychological state of well-being, the variables which determine satisfaction with sexual life and the effects of a positive assessment of the body image. **Material and methods:** 31 women, aged between 39-69 years old (M = 57 ± 7.8), mastectomized after breast cancer answered a survey regarding body image, sexual activity and quality of their sex life. The age when they underwent the intervention was between 33 and 67 (M = 48.30 ± 7.5). 45.6% of the surveyed patients are not part of a couple (they are single, divorced or widows). **Results:** 55% of subjects are unhappy with their body image, when looking in the mirror. 48.39% no longer have any sexual activity, or that they are very unhappy with it. Weakly positive correlations have been recorded between satisfaction with one's physical appearance and the frequency of sexual intercourse (r = .44*, p = .020), as well as the belief in one's own attractiveness (r = .41, p = .033). Strongly positive correlations have been highlighted between the level of libido and sexual satisfaction (r = .98**, p = .00), as well as between the comfort and relaxation during sexual acts and sexual satisfaction (r = .92**, p = .00). **Conclusions:** the quality of life is strongly influenced by the level of satisfaction regarding the body image, the relationship with the significant other and the quality of sexual activity. The "level of education" variable was correlated positively with all variables regarding the body image and sexual life. **Keywords:** MASTECTOMY, QUALITY OF LIFE, BODY IMAGE, SEXUAL SATISFACTION, PSYCHOLOGICAL DISTRESS.

Breast cancer is the most frequent form of cancer diagnosed in women (23% of all neoplastic cases) and it represents the main cause of death by cancer; 14% of fatalities are due to neoplasia (1) and breast surgery impacts psychosocial life, reflecting on the patient's femininity, on body image projection and, indirectly, on behavior and social integration (2).

The psychological impact of mastectomy is generated by stress and the feeling of disfigurement caused by losing the breast, to which one may add anxiety generated by the pathology threatening the vital prognosis (3).

Psychological health, a satisfactory relationship with one's partner and sexual life are important factors in the quality of life for a woman affected by breast cancer and mastectomy. Under these circumstances, at an overall assessment, the loss of a breast represents only a relatively unimportant

problem, by comparison with the negative effects produced by this loss. Sexual health refers to interest, dysfunction and satisfaction within intimate relationships.

The parameters which may measure sexual satisfaction in women are linked to the number of sexual acts, the level of sexual desire, the subjective experience of arousal, vaginal lubrication, genital sensations, number of orgasms etc., generally referring to the comfort perceived by the patient during the sexual act (4). Many of these indicators, referring to vaginal dryness, emotional well-being, the quality of relations with the partner and sexual problems, may be important factors in medical and psychological counseling.

Some studies show that there is a positive correlation between sexual difficulties and variables such as: age, marital status, postoperative chronic fatigue and the therapy method (hormonal therapy, chemotherapy or radiotherapy) (5).

A study conducted on 41 mastectomized women found that, though most of them showed a high rate of adaptation to circumstances, there were obvious signs of psychological suffering, such as suicidal thoughts or anti-health behaviors (use of alcohol and tranquilizers). Premorbid data, age and social support are factors that may signal the necessity for quick psychotherapeutic intervention, especially during the period preceding surgery, when distress is stronger (6). The same authors found that, in partners of mastectomized patients, though the rate of adaptation was relatively high, as in their female partners, a high rate of distress was identified in a subgroup; the causes were sexual restrictions within the couple, the female partner's body image after the surgical intervention and frequent visits to the hospital (7).

MATERIAL AND METHODS

From January to May 2015, 31 women diagnosed with breast cancer and mastectomized answered a survey regarding aspects of the quality of life. The research was approved by the Research Ethics Committee of "Grigore T. Popa" University of Medicine and Pharmacy of Iaşi. The surveys were filled in after the initial training of the patients and after they signed the informed consent form.

The survey included information about socio-demographic data, family history (hereditary collateral antecedents), co morbidities, data about the illness (diagnosis, age at surgery), treatment and type of surgical intervention, ways of information about the possibility of breast reconstruction, the source of information and reasons why breast reconstruction surgery was not resorted to up to the time of the survey.

The items also covered femininity, bodily self-perception, confidence felt around people of the same or the opposite sex, satisfaction with one's physical appearance, satisfaction regarding the relationship with the significant other (frequency of sexual intercourse, libido, comfort and relaxation during sexual acts and the level of sexual satisfaction). Socio-demographic variables taken into account included age, background, level of education, marital status, number of children; medical variables taken into account: level of depression, data about the surgical intervention and type of therapy (hormonal therapy, chemotherapy, radiotherapy and targeted therapy).

Answers for the items targeting physical aspects and the relationship with the significant other were quantified by an ordinal scale with four values, where 1 – very dissatisfied, 2 – a little dissatisfied, 3 – satisfied, 4 – very satisfied. Items targeting

femininity and self-confidence were also quantified by a scale with four values, where 1 – to a very small extent, 2 – to a small extent, 3 – to a large extent and 4 – to a very large extent.

The data obtained have been processed by means of the SPSS 22.0 statistical software.

RESULTS

Demographic data show that most patients (93.1%) come from an urban background; 6.9% come from a rural background. Ages range between 39-69 years old, with an average age of 57.22 ± 7.85. Patients who answered the survey had undergone surgical intervention 1-21 years prior to it. Their age when undergoing removal surgery for a malignant breast tumor was between 33 and 67 years old, with an average age of 48.30 ± 7.54.

Regarding the level of education, 50% of patients have university degrees, 30% have high school education, 6.67% have secondary education and 13.32% have primary or no formal education. In terms of marital status, 6.45% are unmarried, 54.84% are married, 25.81% are divorced and 12.90% are widows. A total of 45.6% of the investigated patients are not part of a couple. The "number of children" variable has been taken into account and it has turned out that 12.90% of the patients do not have children, 41.94% have one child, 38.71% have two children and 6.45% have three children.

Medical data. Approximately half of the investigated patients (46.67%) have various associated conditions (other oncological pathologies, arterial hypertension, diabetes etc.), 46.67% have declared that they have no associated conditions and 6.67% claim not to be aware of the existence of other conditions, apart from the one they have undergone surgery for. 50% of the patients declare they have no family history concerning pathologies of oncological character, 30% have such family history (parents, siblings or extended family) and 16.67% claim not to know about the existence of such diagnoses in close relatives.

The subjects have also been questioned about the reasons why they did not resort to breast reconstruction. The patients bring forth financial reasons (20.69%), fear of illness recurrence (20.69%), the wish to avoid a new surgical intervention (37.93%) or the disinterest in physical appearance (27.59%). 6.9% claim not to have known that such surgical intervention can be performed in Romania.

Survey results. The items were aimed at identifying the level of satisfaction with the following aspects connected to femininity, body image, and relationship with the significant other and sexual satisfaction: the postoperative scar; her appearance when she looks in the mirror; the way she looks from a physical point of view; her confidence around other women; her confidence around men; the relationship with the significant other; the desire to make love / to have sex (level of libido); the frequency of sexual intercourse; her sexual satisfaction; her comfort and relaxation during sexual intercourse; the belief that she is attractive while naked; the sense of femininity.

The answers were assessed on a scale of 1 to 4 (where 1 = very dissatisfied, 2 = a little dissatisfied, 3 = satisfied and 4 = very satisfied) and the results obtained are detailed below. Concerning satisfaction with the postoperative scar (M = 2.73 ± 1.11), of all patients surveyed, 19.23% are very dissatisfied, 19.23% claim to be a little dissatisfied, 30.77% are satisfied and

30.77% claim to be very satisfied with the aspect of the postoperative scar.

Under the item questioning their appearance when they look in the mirror, 22.22% of all patients declare they are very dissatisfied, 25.93% are a little dissatisfied, 33.33% are satisfied and 18.52% are very satisfied.

In what concerns satisfaction with the self-perception of the body image, over 35% are very dissatisfied or a little dissatisfied with their physical appearance, 25% are satisfied and 39.29% are very satisfied with their physical appearance.

A minority of the surveyed women (7.69%) did not wish to answer the item referring to confidence around people of the opposite sex (tab. I).

TABLE I

Confidence felt around women and men

Item	very dissatisfied	a little dissatisfied	satisfied	very satisfied
Confidence felt around other women	7.41%	29.63%	40.74%	22.22%
Confidence felt around men	7.69%	23.08%	42.31%	19.23%

Under the item aimed at identifying satisfaction with the frequency of sexual intercourse, 25.81% of the patients surveyed have declared they no longer have sexual activity, 22.58% are very dissatisfied, 12.90% are satisfied and 29.03% are very satisfied with the frequency of their sexual intercourse.

In terms of the desire to make love, 21.43% of the patients surveyed did not wish to answer the question, 25% declared themselves to be very dissatisfied, 14.29% are a little dissatisfied, 28.57% are satisfied and 10.71% of respondents have claimed to be very satisfied with their level of libido. The items were also aimed at the sexual activity of mastectomized women and the quality of their sexual intercourse (comfort, relaxation, satisfaction). The values obtained are shown below (tab. II).

TABLE II

Satisfaction with sexual intercourse

Item	Did not answer	Very dissatisfied	A little dissatisfied	Satisfied	Very satisfied
Sexual satisfaction	21.43%	21.43%	17.86%	25%	14.29%
Comfort and relaxation during sexual intercourse	22.22%	18.52%	11.11%	33.33%	14.81%

Regarding the item aimed at satisfaction with the self-perceived attractiveness while naked, only 18.51% of the patients claim to be satisfied or very satisfied with it. The rest of the women state that they are very dissatisfied (11.11%) or a little dissatisfied (44.44%). 3.7% of the surveyed women did not answer this item. In what concerns femininity, 17.86% mention they are very dissatisfied, 25% are a little dissatisfied, 35.71% are satisfied and 21.43% claim to be very satisfied with their femininity.

This research has also included a *correlational study*, aimed at identifying variables which influence the level of satisfaction with the body image, the relationship

with the partner and femininity. The study emphasizes the fact that patients' age, marital status and number of years passed since the surgery, do not influence the relationship with their partner, sexual activity, the level of assessment of the body image or femininity.

Positive correlations were identified between all other research items. Weak positive correlations were recorded between satisfaction with one's physical appearance and the frequency of sexual intercourse (r = .44*, p = .020), as well as the confidence about one's own attractiveness (r = .41, p = .033), in that, the more satisfied the patient feels with her physical appearance and the more attractive she feels, the more the frequency of her sexual acts increases.

Positive correlations were obtained between all aspects investigated and the level of education. The higher the level of studies, the higher the satisfaction with the self-image, one's physical appearance, one's confidence around other people and in relationship with the significant other. The level of education seems to have a positive influence on physical and relational self-evaluation.

Strongly positive correlations have been highlighted between the level of libido and sexual satisfaction (r = .98**, p = .000), as well as between the comfort and relaxation during sexual acts and sexual satisfaction (r = .92**, p = .000) (tab. III).

**. Correlation is significant at the 0.05 level (1-tailed).*

DISCUSSION

The data obtained during this study prove that satisfaction with the body image has a significant positive influence on the quality of sexual activity (the frequency of sexual acts, sexual satisfaction, the comfort and relaxation experienced during sexual intercourse) and on relationships with the people around (patients with high scores in body image assessment have also obtained high scores in the items referring to the confidence felt around women or men).

Though a significant percentage of the subjects did not give answers to items referring to sexual life, this may be explained by the fact that 45.6% of the investigated patients are not part of a couple (they are single, divorced or widows).

Despite the fact that studies about the relation between the body image and the level of education are more frequent in what regards children and teenagers, it is important to note that a considerable influence of the level of education on all aspects of the research has been identified. The level of education seems to have a positive influence on bodily self-esteem, confidence and relating to others.

The body image is a subjective concept, depending on the person's psychological universe. The body image is defined as a person's mental image of the physical body, the attitude toward the physical self, health status, normal functioning and sexuality (4). It is manifesting at the level of the feminine gender by one's desire to be attractive and by femininity. The psychological well-being is thus determined by the body self-evaluation, which, in its turn, has positive effects on sexuality (8).

Many studies have identified the fact that mastectomized patients, with or without chemotherapy, have been reporting problems related to their sexual activity. Sexual problems and sexual functioning issues seem to persist over time, even many years after the breast removal surgery (9, 10).

The vicious circle of the body image is recharged by the increase in mental distress, which, in its turn, will affect the self-image and the desire to engage in sexual activity. In this situation, the multidisciplinary intervention for preoperative physical and mental preparation, as well as postoperative psychological and medical therapy, should take into account the quality of mental life in order to determine the best type of individual and couple therapy (11, 12). Other studies researching quality of life on mastectomized patients for breast cancer, with instruments that measure both physical and emotional impact, have been shown that females' activities are negatively influenced for more than half of the study groups, no matter the stage of the cancer evolution (metastatic or not) (13, 14).

CONCLUSIONS

In our study we found out that the quality of life for mastectomized patients is strongly influenced by the level of satisfaction with the body image, the relationship with the significant other and the quality of sexual activity. The age at which the surgical intervention was performed and the length of time passed since the surgery do not influence the quality of life. We showed highly significant correlations between satisfaction and body image and the quality of sexual activity (the frequency of sexual intercourse, sexual satisfaction, level of libido). The "level of education" variable positively correlates with all variables referring to body image and sex life. The study shows that preoperative psychological intervention and psychological

support following the surgery are important for both the patient's and the couple's quality of life.

ANTIBIOTIC RESISTANCE SPECTRUM OF NON FERMENTING GRAM NEGATIVE BACILLI ISOLATED IN THE ORTHOPEDIC TRAUMATOLOGY CLINIC OF „SF. SPIRIDON" CLINICAL EMERGENCY HOSPITAL IAŞI (Abstract) **Aim:** The retro-prospective analysis of antibiotic sensitivity of non-fermenting gram negative bacilli strains circulating in the Orthopedics-Traumatology Clinic from "Sf. Spiridon" Emergency Clinical Hospital in view of determining the trend of the resistance phenomenon and indicating the most useful treatment for the infections caused by these strains. **Material and methods:** The retrospective component was conducted from 01.01.2003 to 31.12.2012, and the result of the diffusimetric antibiograms was taken from the hospital's informatics system; the prospective component of the study involved the collection of pathological products from the patients admitted during January - December 2013, who showed clinical suspicion of infection, in compliance with the general collection norms for the products destined for the bacteriological exam. **Results:** From the total 167 strains of *Pseudomonas aeruginosa* isolated and identified from the patients, 48 (28.74%) were sensitive to at least one antibiotic from each tested class, 29 (17.39%) were resistant to a single antibiotic and the rest of 90 (53.89%) showed multiple resistance. We noticed a statistically significant difference between the number of strains sensitive to at least one antibiotic from each tested class and those with multiple resistance ($p<0.05$). For the strains of *Acinetobacter baumanii* combined resistance was identified for 121 (87.04%), out of which 55 (39.56%) were resistant to two classes of antibiotics and the other (47.48%) to all three classes. The most frequently met was the association of resistance to quinolones and aminoglycosides, namely for a number of 49 strains (35.25%); only 3.59% of them were simultaneously sensitive to the three classes of antibiotics. **Conclusion:** The already high percentages and the rising trends of antibiotic resistance of non-fermenting gram-negative bacteria described in this study confirm the continuous decrease of the efficiency of antimicrobial agents and underline the necessity of a global strategy which aims at all health sectors regarding the rational use of antibiotics, on the one hand, and the continuation of studies concerning the surveillance of the antimicrobial resistance phenomenon, on the other hand. **Key words**: NON-FERMENTING GRAM NEGATIVE BACILLI, ANTIBIOTIC RESISTANCE, COLISTIN.

The involvement of *Pseudomonas aeruginosa* and *Acinetobacter baumanii* gram negative bacilli in nosocomial infections is continuously rising, being accompanied by an increased mortality rate (1, 2). Due to the special structural characteristics of their external membrane, these bacteria show antibiotic multi-resistance (3).

The infections caused by *P. aeruginosa* show a high risk especially for patients in critical condition or with compromised immunity (4). The colonization rate with pyocyanic bacillus grows for patients with prolonged hospitalization and/or those who received broad-spectrum anti-infections chemotherapy. In the last ten years, *A. baumanii* has become one of the most frightening pathogen because the treatment of infections caused by this microorganism is limited to a handful of antibiotics due to the various antimicrobial resistance mechanisms it displays. Multi-drug resistant strains (at least three antibiotic classes) are more and more frequently reported at world level (5). The infections determined by these strains are associated with high morbidity and mortality rates (6). Unfortunately, the carbapenem resistance is continuously rising and no longer constitutes the "saving" therapy in *A. baumanii* infections (7). The purpose of this study was to make a retro-prospective analysis of antibiotic sensitivity of non-fermenting gram negative bacilli circulating in the Orthopedics - Traumatology Clinic of "Sf. Spiridon" Emergency Clinical Hospital Iaşi, in view of determining the trend of the resistance phenomenon and indicating the most useful treatment for the infections caused by these strains.

MATERIAL AND METHODS

The retrospective study was conducted during 01.01.2003-31.12.2012, and the result of the diffusimetric antibiograms was taken from the hospital's informatics system; the prospective component of the study involved the takeoff of pathological products from the patients admitted from 01.01.2013 to 31.12.2013, who showed clinical suspicion of infection, in compliance with the general collection norms for products destined to bacteriological exam. We excluded from the data base strains from the same bacterial species and with an identical resistance phenotype to anti-infectious chemotherapy drugs isolated from the same patient. The strains were isolated and identified in the Microbiology Laboratory of "Sf. Spiridon" Emergency Clinical Hospital and in the Microbiology Laboratory within "Gr. T. Popa" University of Medicine and Pharmacy Iaşi. The test of antibiotic sensitivity was conducted using two methods: diffusimetric - Kirby-Bauer and of MIC (minimal inhibitory concentration) determination using the E-test (for *P. aeruginosa* strains, isolated in 2013), and the interpretation of sensitivity was made in a standardized manner, in compliance with the CLSI standard (*Clinical and Laboratory Standards Institute*) for antibiotic testing in force at the moment (8).

RESULTS

In the study period we isolated and identified 167 strains of *P. aeruginosa* and 139 of *A.baumanii.*

Testing sensitivity to aminoglycosides. The mean value of the frequency of resistant *P. aeruginosa* strains was of 45.85%±26.5 for amikacin (AMK), namely of 57.41%±22.9, for gentamicin (GEN). Gentamicin resistance of *A. baumanii* strains was extremely high, eight years in a row reaching 100%, the mean resistance to this antibiotic for the whole duration of the

study being of 87.85%±26.83. The mean resistance to amikacin was 93.74%±11.61, and out of the six years of testing in four was observed a 100% resistance (tab. I).

TABLE I

Aminoglycosides resistance depending on the year of study

		years of study											
ANTIBIOTIC		2003	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	Mean ± SD
AMK (%)	***P. aeruginosa***	58.33	17.85	21.42	0.00	50.00	66.66	70.00	NT	75.00	30.00	69.23	45.85 ± 26.5
	A. baumanii	NT	93.8	100.0	100.0	100.0	100.0	NT	NT	NT	NT	33.3	93,74±11,61
GEN (%)	***P. aeruginosa***	41.66	32.14	21.42	27.27	66.66	66.66	70.00	63.63	87.50	70.00	84.61	57.41±22.9
	A. baumanii	86.7	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	77.8	66.7	87,85±26,83

In the case of *P. aeruginosa* strains, the tendency calculated in the period 2003-2013 was on the rise for aminoglycosides (y=5,8226x+22,478 for gentamicin and y=4,107x+23,259 for amikacin), even if these frequencies decreased in the last two years.

Testing sensitivity to quinolones. GNB (Gram negative bacilli) were tested, depending on the year, both for 2nd generation quinolones, such as pefloxacin (PFX) and ciprofloxacin (CIP), and for 3rd generation quinolones, such as levofloxacin (LVX) (tab. II).

TABLE II

Quinolone resistance depending on the year of study

		Years of study											
ANTIBIOTIC		2003	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	Mean ± SD
CIP (%)	***P. aeruginosa***	41.66	96.42	85.71	9.09	75.00	55.55	70.00	54.54	62.50	50.00	84.61	62.28±24.38
	A. baumanii	NT	NT	NT	100.0	100.0	100.0	100.0	100.0	100.0	NT	75.0	96,42±9,44
LVX (%)	***P. aeruginosa***	NT	25.00	14.28	9.09	50.00	55.55	70.00	45.45	75.00	60.00	84.61	48.89±25.68
	A. baumanii	NT	81.3	72.7	66.7	100.0	100.0	100.0	100.0	100.0	NT	75.0	88,41±14,32
PFX (%)	***P. aeruginosa***	50.00	92.85	85.71	72.72	100.00	NT	NT	NT	NT	NT	NT	80.25±19.68
	A. baumanii	80.0	100.0	100.0	100.0	100.0	100.0	NT	NT	NT	NT	NT	96,66±8,16

The highest frequency of *P. aeruginosa* strains resistant to ciprofloxacin was noticed in 2004 (96.42%), followed by 2005 (85.71%). Even if in the following years these frequencies decreased, the trend calculated for the eleven years of study was slightly increasing (y=0.4122x+59.807), as compared to LVX (y=7.1932x+9.3353). Even if for pefloxacin both strains were tested only for 5 years (2003-2007) one can notice from table II that the resistance was on a continuous rise, reaching 100%, reason for which the strains were no longer tested for this antibiotic.

Testing sensitivity to carbapenems. The percentage of *P. aeruginosa* strains resistant to carbapenems varied depending on the year and the tested antibiotic. The high-

est frequency of strains resistant to imipenem (IPM) was noticed in 2013 (84.61%), the lowest one being in 2003 (8.33%) showing a clear trend of increase of the resistance to this antibiotic. If, in the first three years of study, the frequency of *P. aeruginosa* strains resistant to etanercept (ETP) varied between 27.27% (2006) and 32.14% (2003), in 2007 it rose to 75%, reaching values of 100% in 2008-2011. Out of the few classes of antibiotics to which the *A. baumanii* is still sensitive, the carbapenems have rather good results. But, even in their case, the mean resistance of strains was of 52.60%±28.67 to IPM and of 98.70%±3.18 for ETP (tab. III).

TABLE III

Carbapenems resistance depending on the year of study

		Years of study											
ANTIBIOTIC		2003	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	Mean ± SD
IPM (%)	***P. aeruginosa***	8.33	14.28	35.71	45.45	58.33	55.55	80.00	45.45	37.50	40.00	84.61	45.92±23.51
	A. baumanii	13.3	0.0	27.3	50.0	66.7	85.7	78.6	70.0	78.6	66.7	41.7	52,60±28,67
ETP (%)	***P. aeruginosa***	NT	32.14	28.57	27.27	75.00	100.00	100.00	90.90	100.00	NT	NT	69.23±34.08
	A. baumanii	NT	NT	NT	100.0	100.0	100.0	100.0	100.0	92.9	NT	NT	98.70±3.18

Starting with 2009, the *P. aeruginosa* and *A. baumanii* strains were tested for colistin as well, the sensitivity to this antibiotic being of 100%, in 2009-2013. For 12 strains of *P. aeruginosa* isolated in 2013 we determined the MIC, by the E-test, for colistin; this varied between 0.5-1.5 mg/ml. Regardless of the MIC value to colistin, out of the 12 strains 10 were MDR (multi-drug resistant) and only 2 were also sensitive to amikacin, beside colistin.

Cross resistance. Given the fact that all the tested strains were sensitive to polymyxin E (colistin), cross resistance was observed for the following five classes of antibiotics: aminoglycosides, 3rd generation cephalosporins (ceftazidime), quinolones, penicillins associated with β-lactamase (TZP-tazobactam) and carba-penems.

Of the total 167 strains of *P. aeruginosa* isolated and identified from patients in the eleven years of the study, 48 (28.74%) of them were sensitive to at least one antibiotic from each testes class, 29 (17.39%) were resistant to a single antibiotic and the rest of 90 (53.89%) showed multiple resistance. There is a statistically significant difference between the number of strains which are sensitive to at least one antibiotic from each tested class and the number of strains with multiple resistance ($t=-4.251$; $p<0.05$).

From the strains with multiple resistance, 21 (12.57%) were tested for two classes of antibiotics, 12 (7.18%) for three classes, 18 (10.77%) for 4 classes and most of them, 39 (23.35%), for all five classes. Of the 29 strains which showed resistance to a single class of antibiotics, most of them were resistant to carbapenems (15 strains) and the fewest were resistant to ceftazidime. The most frequent association of two antibiotics, to which *P. aeruginosa* proved resistant, was represented by the association of TZP+ceftazidime (6 strains) and quinolones + aminoglycosides (5 strains), respectively.

In the case of strains resistant to four classes of antibiotics, 11 strains out of 18 associated cross resistance to: TZP + fluoro-

quinolone+ aminoglycosides + carbapenems, 6 strains to: TZP + fluoroquinolones + aminoglycosides + ceftazidime, and another strain to fluoroquinolones + aminoglycosides + carbapenems + ceftazidime. Cross resistance to all five classes of antibiotics was noticed starting with 2004 (4 strains) and continued until 2013 (13 strains).

In the case of *A. baumanii* strains, only 5 (3.59%) of them were sensitive simultaneously to the three classes of antibiotics tested (quinolones, carbapenems, aminoglycosides), the rest being resistant to at least one antibiotic from each class.

Combined resistance could be observed with 121 strains (87.04%), out of which 55 (39.56%) were resistant to two classes of antibiotics and the rest of 66 (47.48%) to all three classes. The most frequently met was the association of resistance to quinolones + aminoglycosides, namely 49 strains (35.25%) (tab. IV).

Resistance to a single class of antibiotics could be observed only for 13 strains (9.35%), the relation between fluoroquilones and aminoglycosides being fairly equal. We couldn't identify any strain resistant only to carbapenems.

TABLE IV
Antibiotics resistance pattern for *A. baumanii* strains

Resistance *Pattern*	Europe 2012 (%)	Our study (%)
Sensitive to all tested classes	27.1	3.59
Resistance to a single class of antibiotics		
TOTAL	**4.9**	**9.35**
Quinolones	3.4	4.31
Aminoglycosides	0.9	5.03
Carbapenems	0.6	0
Resistance to two classes of antibiotics		
TOTAL	**17**	**39.56**
Quinolones + Aminoglycosides	8.2	35.25
Quinolones + Carbapenems	8.5	2.87
Aminoglycosides + Carbapenems	0.3	1.43
Resistance to three classes of antibiotics		
Aminoglycosides + Carbapenems + Quinolones	**51**	**47.48**

Of the strains which associated resistance to all the three classes of antibiotics, the most numerous were isolated in 2009 and 2011. Even if in 2013 we identified only 4 resistant strains, simultaneously for all 3 classes, the general linear trend is rising ($y=0.8182x+1.0909$).

DISCUSSION

P. aeruginosa is resistant to most antimicrobial agents due to its selective ability of the outer membrane. The antibiotic classes to which *P. aeruginosa* is also sensitive are: fluoroquinolones (ciprofloxacin + levofloxacin), aminoglycosides (gentamicin, amikacin and tobramycin), certain β-lactamases (piperacillin + tazobactam, ceftazidime, cefepime, imipenem, doripenem and meropenem) and poly-myxins (polymyxin B and colistin).

All presented results indicate the fact that there is an increase of the circulation of

strains which became resistant to the most frequently used antibiotics. Starting with 2005, EARSS (European Antimicrobial Resistance Surveillance System) started to centralize data regarding antibiotic resistance of *P. aeruginosa* strains. In the case of carbapenems we took into account imipenem resistance, the mean frequency of resistant strains being of 45.92%±23.51 (9). According to the data reported by EARSS, carbapenems resistance for Romania was of 34.20%±26.16, without a statistically significant difference (t=1.65, GL=10, p=0.129). Furthermore, in 2012, in Europe was reported a rate of strains resistant to this class of antibiotics of 17.1%, varying from 3.2% in Malta, to 51.2% in Romania (9). In the same year, IPM resistance in the case of strains isolated in the Orthopedics - Traumatology Clinic was 40%.

In 2012, the resistance reported for fluoroquinolones was of 21% in Europe, varying from 0% in Malta, to 56.3% in Slovakia (9); in our study, CIP resistance was of 50% and LVX resistance of 60%. The mean frequency of *P. aeruginosa* strains resistant to fluoroquinolones in the period 2005-2013 was of 44.16%±20.87 for Romania, and in our study of 62.28%± 24.38 for CIP and 48.89%±25.68 for LVX, with statistically significant differences only in the case of CIP (t=2.465, GL=10, p=0.033). The increased CIP resistance is explained by its frequent use in the hospital environment (10).

For aminoglycosides, the mean frequency of resistant strains was 44.75%±16.1 for Romania, and in our study it was very close, (45.85%±26) for AMK and 57.41%± 22.9 for GEN, with no statistically significant differences. In 2012, in Europe this level of resistance was, on the whole, of 18.4%, varying from 0%, in Iceland to 48.8% in Romania, once again "leading" the top. In the same year, isolated strains in our study had a resistance of 30% to amikacin and 70% to gentamicin.

After analyzing the data reported by Romania to EARSS for 2005-2012 (9) we noticed a general increasing trend of resistance to aminoglycosides, fluoroquinolones, the most important rising tendency being in the case of carbapenems.

Aminoglycosides generally have a good activity against the most important GNB. According to our study, 45.85% of the strains were resistant to amikacin. This percentage is much higher as compared to the one reported by Carvallo et al. (11) (namely 14%). Miller et al. (12), state that the resistance pattern to aminoglycosides is affected by the selective pressure of antibiotics, with higher variations among various regions, a phenomenon related to the "abuse" of antibiotics therapy.

In 2012, the percentage of multiple resistance strains (to more than three classes of antibiotics) of *P. aeruginosa* varied from 0% in Malta, 1.7% in Great Britain and 1.8% in Denmark, to 46.3% in Romania, which ranked first in Europe (9). The emergence of MDR strains of *P. aeruginosa* is continuously rising all over the world and is a major problem in the management of these infections (13), a fact also corroborated by the analysis of the data reported by Romania to EARSS.

From the total of *P. aeruginosa* strains, only 48 were sensitive to all classes of antibiotics, 29 were resistant to a single class and the rest of 90 (53.89%) were resistant to at least two classes and classified as MDR. These data are very similar with those in the study conducted by Strateva et al.(13) (49.8%).

A. baumanii was included in *EARS-Net*

(European Antimicrobial Resistance Surveillance Network) only in 2012, when several member states noticed an increase of antibiotic resistance of this microorganism. The percentage of strains sensitive to all antibiotics was, on average, in Europe, of 27.1% (9), varying from 4.2% in Romania, to 100% in Netherlands. According to our study, on the whole duration of the eleven years, the percentage of strains sensitive to all tested classes was only of 3.59%, the rest of 96.41% being resistant to at least one class of antibiotics and for 2012, out of the 18 strains which were isolated, none was sensitive to all antibiotics and 50% (9) strains were resistant simultaneously to fluoroquinolones, aminoglycosides and carbapenems, being sensitive only to colistin.

Moreover, according to the same *EARS-Net* report, fluoroquinolones resistance was of 90%, aminoglycosides resistance of 54.2% and carbapenems resistance of 81.3%. These data are partially similar to the presented data, since the aminoglycosides resistance signaled by us was much higher (86.8% to amikacin and 92.8% to gentamicin), with statistically significant differences ($p<0.001$). In the case of carbapenems, the resistance was much lower to imipenem (52.8% *vs.* 81.3%), a statistically significant difference ($p<0.001$). On the other hand, in the case of fluoroquinolones, the percentage of resistant strains was approximately equal (88.41% - LVX and 96.66% PFX *vs.* 90%), with no statistically significant difference.

In Europe, aminoglycosides resistance varied from 1.7% in Netherlands to 83.1% in Italy, for carbapenems varied from 0% in Norway to 87.8% in Italy and for fluoroquinolones from 0% in Netherlands and Norway to 93.1% in Greece. It seems that there are very great variations with regard to antimicrobial resistance of *A. baumanii* strains in Europe, most resistant strains being met in Southern Europe as compared to the countries from the north of Europe, most likely due to the selective pressure exercised by the anti-infectious therapies used in excess.

The global spread of *P. aeruginosa* and *A. baumanii* strains resistant to carbapenems is a major concern given the fact that carbapenems are frequently used in the treatment of such infections (14).

CONCLUSIONS

In the case of *P. aeruginosa* strains, the highest resistance was noticed for aminoglycosides and quinolones, all strains being sensitive to colistin; out of all tested strains, approximately one fourth associated cross resistance to the four classes of antibiotics.

A. baumanii strains showed an extremely high resistance to all tested antibiotic classes, the lowest being met in case of IPM testing (52.6%); all tested strains were sensitive to colistin; cross resistance to three antibiotic classes was identified at half of the strains, which is a major concern.

P. aeruginosa is found on the list of the main bacteria responsible for the infections associated with the sanitary system, being classified among the first five etiologic agents of nosocomial infections. In our country we noticed a net increase of resistance to all tested antibiotic classes, more important in the case of carbapenems, a trend also illustrated by our study.

Colistin resistance of *P. aeruginosa* and *A. baumanii* strains is still considered extremely rare, although several cases were reported, while not in our country. Unfortunately, this antibiotic which is part of the

high toxicity category remains the last therapeutic resort in the infections caused by these microorganisms, especially because the frequency of MDR strains is high.

The already high percentages and the rising trends of antibiotic resistance for Gram-negative bacteria, including non-fermenting ones, described by this study, show the continuous decrease of the efficiency of antimicrobial agents against these microorganisms and underline the necessity of a global strategy focused on all health sectors.

THE DISCONTENT DEGREE IN RELATIONS WITH THE PROXIMAL SOCIAL ENVIRONMENT AND ADOLESCENT PERSONALITY FEATURES IN TIMIS COUNTY, ROMANIA (Abstract): In our study we investigated whether there is a relation between the degree of discontent in relations with the proximal social environment (family and peer groups) and adolescent personality features. The study was conducted on a statistical representative and homogenous sample consisting of 2908 teenagers (51.5% girls and 48.5 % boys, aged between 15 and 19 years). It was an observational (case) study and it consisted in 2 questionnaires applying: Freiburg Personality Inventory (212 items) and CORT 2004 questionnaire (116 items, 6 referring to the discontent levels created by proximal social environment). Cronbach`s alpha index was 0.802 for FPI and 0,910 for CORT 2004. Statistical analysis was performed by SPSS 16 program applying Chi square (χ^2) and gamma (γ) correlation. Results: Depression and Emotional lability correlated positively and powerfully with q15 (discontent degree of relations with present friend-peers) (γ= 0.471, Sig. 0.000, and γ= 0.383, Sig. 0.000, respectively) and q5 (discontent degree of the relation with parents) (γ= 0.380, Sig. 0.000, and γ= 0.337, Sig. 0.000, respectively). Sociability and calm correlated negative with q5 (γ=- 0.14, Sig. 0.000, and γ = - 0.35, Sig. 0.000, respectively), q15 (γ = - 0.33, Sig. 000 and γ = - 0.18, Sig. 000, respectively). In conclusion, there is direct proportional relation between the discontent degree of relations with friend-peers and parents and depression and emotional lability, and inverse proportional relation of friend-peers and parents with sociability and calm. **Keywords:** PROXIMAL SOCIAL ENVIRONMENT, FAMILY, PEERS, PERSONALITY FEATURES.

Adolescence is a developmental stage in which experiencing relationships with people around becomes important in social integration. The proximal social environment consists of family (parents, siblings), school-peers and friend-peers outside the school. The relationships system affects powerfully the developing adolescent personality, which prepares them for social competencies in adult life (1). Adolescence is a stage in which the person passes through all the previous developmental stages (recycling) (2).

MATERIAL AND METHOD

The aim of our study was to investigate the relationship between the discontent level created by proximal social environ-

ment (family and peers) and adolescent personality features. The material consisted of a statistically representative (2908 teenagers) and homogenous (51.5% girls and 48.5 % boys, aged between 15 and 19 years) sample. It was stratified in nests, the sample unit being the class group. This study was an observational one (case study) and consisted in two questionnaires: Freiburg Personality Inventory (FPI - 212 items) (3, 4) normalized for Romanian population and CORT 2004 (116 items of which 6 referred to discontent degree of relations in proximal social environment). The questionnaires were applied individually and anonymously. The application time for both questionnaires was 60 minutes. Personality items referred to: Nervousness (Nrv), Aggressiveness (Agr), Depression (D), Excitability (Exc), Sociability (Soc), Calm (Clm), Domination (Do), Inhibition (Inh), Sincerity (Snc), Extraversion (Exv), Emotional lability (Lbl) (bipolar features of the personality profile). The CORT 2004 items, which measured the discontent degree of relations in proximal social environment, were: Q1 (organized and disorganized family), Q5 (relation with parents), Q6 (relation with siblings), Q10 (financial status of the family), Q14 (relation with school-peers), and Q15 (relation with present friend-peers). Cronbach`s alpha index was 0.802 for FPI and 0,910 for CORT 2004. Statistical analysis was performed by SPSS 16 program applying Chi square ($\chi^2$) and gamma ($\gamma$) correlation. The 9 ranks of personality features` intensity were reduced to 3 (1=1,2,3; 2=4,5,6; 3=7,8,9) in order to avoid the small number of cases.

RESULTS

We registered a significant statistical difference between the degree of family disorganization (q1) regarding certain personality features (depression, excitability, sincerity, emotional lability), with Chi Square: χ^2=9.97, Sig. 0.04; χ^2=15.37, Sig. 0.004; χ^2=21.1, Sig 0.000, and χ^2=13.97, Sig. 0.007, respectively, (tab. I).

The discontent degree in the relationship with parents (q5: 1-content, 2-nor content, neither discontent, 3-discontent, 4-no parents) related strongly with 11 dimensions of the personality profiles: nervousness, aggressiveness, depression, excitability, sociability, calm, domination, inhibition, sincerity, emotional lability (tab. II). Main statistical differences between discontent degrees of relations with parents were registered for depression with χ^2 =117,512, Sig. 0.000 and for emotional lability (χ^2 =91,063, Sig. 0.000) (tab. II). The discontent degree of relation with present friend-peers (q15) had a significant statistical difference for 9 personality features of teenagers, more relevant being for depression (χ^2 =117,493, Sig. 0.000) (tab. III). The satisfaction degree of the relation with siblings (brothers and sisters) (Q6) related powerfully with 6 personality features, the highest values being registered for depression (χ^2 =72.753, Sig. 0.000) and emotional lability (χ^2 =52.782, Sig. 0.000) (tab. IV).

The discontent degree of the relationship with parents (q5) correlated with 11 dimensions of the personality profiles, followed by the discontent degree of relationship with present friend-peers (q15 – 9 personality features), and the discontent degree of the relationship with siblings (q6 – 6 personality features), correlation gamma being statistically significant (tab. V).

Depression and emotional lability proved to be the main adolescent personali-

ty features, which relate with the discontent levels of their relation with present friend-peers (q15) (γ=0.471, Sig. 0.000, and γ=0.383, Sig. 0.000, respectively) and with parents (q5) (γ=0.380, Sig. 0.000, and γ=0.337, Sig. 0.000, respectively) (tab. V).

a Not assuming the null hypothesis.

b Using the asymptotic standard error assuming the null hypothesis.

Sociability and calm correlated negative with discontent degree of relation with parents (q5) (γ=- 0.14, Sig. 0.000, and γ = - 0.35, Sig. 0.000, respectively), and discontent degree of relation with present friend-peers (q15) (γ = - 0.33, Sig. 000 and γ = - 0.18, Sig. 000, respectively). Calm correlated negatively with discontent degree of relation with brothers and sisters (q6) (γ = - 0.153, Sig. 0.000), too.

DISCUSSION

The relation with parents proved to be decisive in the process of personality forming, parents being models and modeling factors of it. Failures of this relation are visible in psychiatric pathology or in numerous psycho-pathological processes in adult life. (5).

Schools organize programs aimed at stimulating and orienting resources (motivating) with the objective of avoiding limit or burn-out situations (6).

Life satisfaction was found as protective factor against suicidal thoughts and behaviors in adolescents (7). In a study performed in Poland about the adolescents` optimism, the satisfaction of the relationships with family was significantly associated with life joy both for girls and for boys (8). In another study, the relation with others is presented like a psychological aspect of the wellbeing state (9). Our study finds a direct proportional relation of the discontent degree of relations in proximal social environment (as psychological aspect which can affect the wellbeing state) with emotional lability (positive/negative affects - the subjective aspect of the well-being state) and depression (a result of dissatisfaction in life) (9). An inverse proportional relation between discontent degrees of relations with present friend-peers or parents (social connectivity and balance) (10) and sociability and calm (subjective aspects of wellbeing) (9) was also identified in our study.

CONCLUSIONS

1. There is a relation between discontent degree of relations in proximal social environment and personality features of adolescents (11 for relations with parents, 9 for relations with present friend-peers and 6 for siblings).

2. The discontent degree of relation in family and with present friend-peers relates positively with depression and emotional lability, and negatively with sociability and calm.

3. The results of our study are similar with results in literature as they confirm the existence of a relation between the discontent degree of relations with the proximal social environment (psychological aspect of wellbeing) and personality features of adolescents (subjective aspects of wellbeing state).

EVALUATION OF THE EFFECTS OF DIODE (980 NM) LASER ON GINGIVAL INFLAMMATION AFTER NONSURGICAL PERIODONTAL THERAPY

Periodontitis is an inflammatory disease, for which, scaling and root planning is the common approach for non-surgical control of inflammation. The use of lasers is another approach in the first phase of periodontal treatment for control of inflammation. Diode laser has some beneficial effects such as acceleration of wound healing, promotion of angiogenesis and augmentation of growth factor release. The aim of a study realized by a group of researchers from Iran, was the evaluation of diode laser (980 nm) effect on gingival inflammation when it is used between the first and second phase of periodontal treatment, in comparison with common treatment scaling and root planning modality alone. In the study were included 21 patients with moderate to severe chronic periodontitis, divided in to control group (scaling and root planning) and test group (scaling and root planning + laser). Two months after the last scaling and laser radiation, indexes including gingival level, bleeding on probing and modified gingival index were recorded and compared with baseline. The obtained data showed two months after the beginning of the study, all indices improved in both groups. The indices were not different between two groups except for bleeding on probing which was lower in laser group. Based on overall improvement in parameters such as superiority of laser application in some indices, lack of thermal damage and gingival recession with the specific settings used in this study, the application of laser as an adjunctive treatment together with common methods is preferable (Zare D, Haerian A, Molla R, Vaziri F. Evaluation of the effects of diode (980 nm) laser on gingival inflammation after nonsurgical periodontal therapy. *J Lasers Med Sci*, 2014; 5 (1): 27-31).

MICROPARTICULATE DRUG DELIVERY SYSTEM CONTAINING TRAMADOL HYDROCHLORIDE FOR PAIN TREATMENT (Abstract): The current trend of replacing conventional pharmaceutical forms is justified because most substances administered in this form give fluctuations of therapeutic concentrations and often outside the therapeutic range. In addition, these formulations offer a reduction in the dose or the number of administrations, thus increasing patient compliance. **Aim**: In the experiment, we developed an appropriate technology for the preparation of gelatin microspheres containing tramadol hydrochloride by emulsification/cross-linking method. **Materials and methods**: The formulated microspheres were characterized by product yield, size distribution, encapsulation efficiency and *in vitro r*elease of tramadol hydrochloride. Data obtained from *in vitro* release studies were fitted to various mathematical models to elucidate the transport mechanisms. The kinetic models used were zero-order, first-order, Higuchi Korsmeyer-Peppas and Hopfenberg. **Results**: Spherical microspheres were obtained, with free-flowing properties. The entrapment efficiency of tramadol hydrochloride in microparticles was 79.91% and product yield -94.92%. As the microsphere size was increased, the entrapment efficiency increased. This was 67.56, 70.03, 79.91% for formulations MT80-250, MT8-500 and, MT250-500. High entrapment efficiency was observed for MT250-500 formulation. The gelatin microspheres had particle sizes ranging from 80 to 500 µm. The drug was released for a period of 12 hours with a maximum release of 96.02%. Of the three proposed formulations, MT250-500 presented desirable properties and optimal characteristics for the therapy of pain. Release of tramadol hydrochloridi was best fitted to Korsmeyer-Peppas equation because the Akaike Information Criterion had the lowest values for this kinetic model. **Conclusions**: These results suggest the opportunity to influence the therapeutic characteristics of gelatin microspheres to obtain a suitable drug delivery system for the oral administration of tramadol hydrochloride. **Keywords:** TRAMADOL HYDROCHLORIDE, GELATIN MICROSPHERES, EXTENDED RELEASE, KINETICS MECHANISM, MATHEMATICAL MODELS.

Tramadol hydrochloryde is a synthetic opioid with dual action mechanism (the stimulation of µ receptors and the inhibition reuptake of noradrenalin and seroto-

nin) (1); clinical usefulness is mainly due to high efficiency in moderate and severe pain (trauma, colic pain, post surgery pain or that of oncological nature) but also due to the diminished dependence potential and low risk of respiratory depression, being thus efficient at patients with high cardiovascular risk or pulmonary impairment; also the dual mechanism (especially the augmentation of spinal monoaminergic system) gives it increased efficacy in neuropathic pain (2).

Weak agonist of mu opioid receptors, the compound clinically used is a racemic mixture, (-) - tramadol being an inhibitor of noradrenalin reuptake, being 10 times stronger than (+) - tramadol, which, in turn has an increased capacity to inhibit serotonin reuptake (2, 3).

Hepatic metabolism is CYP2D6-dependent, one of the metabolites (produced by O-demethylation) being pharmacodynamically active with long-term action. Since CYP2D6 is the object of an important genetic polymorphism, at slow metabolizes the analgesic effect can be suboptimum in usual dosage and in the case of fast metabolizers toxicity mediated by μ receptors can occur (4, 5).

Clearance is done by hepatic metabolization (via O-demethylation to form the active metabolite, N-demethy-lation, respectively, both are followed by glucuronide conjugation and sulfo-conjugation); tramadol and its metabolites are mainly renal cleared. Half-life of tramadol is around 5.5-6 hours, but of O-desmethyltramadol is of about 8-9 hours (2, 3, 6).

Given the need for adequate pain control throughout the day and taking into account the short half life, tramadol administration in conventional oral formulations should be made at intervals up to 6 h, up to a total cumulative dose of 400 mg daily (1).

This leads to the conclusion that a formulation with delayed release, which increases plasma concentration level in the 12 hour therapeutic interval is extremely useful, ensuring an enhanced adherence to treatment and a reduced frequency of administration, with an adequate control of pain (3, 6). An optimal formula must ensure a personalized dosage regimen targeted to the patient, independent of daily meals, flexible, with an improved control of background pain or painful flare (7).

Biodegradable polymers are widely used in the development of multi particulate drug delivery systems, and several mechanisms may be responsible for the release of the active ingredient dispersed in a matrix: erosion of the polymer, diffusion of the drug particles through the matrix and dissolution of the drug in the surrounding medium (8).

Naturally macromolecules such as gelatin are extensively used in controlled drug release to maximize the efficacy and facilitate the clinical applicability (9). The gelatin microspheres were prepared by emulsification- formaldehyde-cross-linking method.

The cross-linking reaction causes significant changes in the polymer molecule, it influences certain properties such as the reduction of imbibitions and it limits the dissolution properties of the drug influencing the failure of the microsphere.

In the experiment, we tried to develop an appropriate technology for the preparation of gelatin microspheres, obtaining a good product yield, a higher entrapment efficiency of tramadol hydrochloride and an extended-release formulation with a good efficacy and tolerability. The formulated microspheres were characterized by

product yield, size distribution, encapsulation efficiency and *in vitro* release of tramadol hydrochloride. Data obtained from *in vitro* release studies were fitted to various mathematical models to elucidate the transport mechanisms. The kinetic models used were zero-order, first-order and Higuchi. Mathematical modeling of drug release kinetics provided a basis for the study of mass transport mechanisms that are involved in the control of drug release (9).

MATERIALS AND METHODS

Materials

Tramadol hydrochloride (Hyderabad-Nacharam, India), gelatin type B 180 Bloom strength (Fluka AG), formaldehyde (Riedel de Haen), sunflower oil, isopropyl alcohol, acetone, ethyl ether. All the reagents used were of analytical grade.

Methods

Preparation of tramadol hydrochloride microspheres

Tramadol hydrochloride was dissolved in water and after the required quantity of gelatin to obtain a 25% solution was dissolved in that solution at 60 °C. Polymer drug solution was added drop wise to 100 ml of sunflower oil preheated to 60 °C, with continuous stirring at 300, 500 and 600 rpm. The emulsion was cooled and stirred at 4 °C in an ice bath for 15 minutes. The isopropyl alcohol-acetone solution was added for dehydration, in three stages (ten milliliters for each time) and the stirring was continued at room temperature. The microspheres were separated by filtration using Whatman paper and were washed with anhydrous ether to remove the sunflower oil. After washing, the microspheres were dried at 25°C and transferred to desiccators for a period of 12 hours for cross-linking with formaldehyde.

Product Yield

The product yield of the microspheres was determined using the equation (10):

$$M\ (\%) = \frac{M_0 - M_1}{M_0} \times 100$$

where, M is the mass loss, M_0 is the initial weight of drug and polymer and M_1- the weight of micro particles.

Characterization of microspheres

Particle size analysis

Determination of average particle size was measured by optical microscopy. The microspheres were dispersed in water and a smear was made on a glass slide, and the size of 200 particles was measured. The particle size distribution of the microspheres was plotted, and mean diameter was determined using the following equation (11):

$$D\ (\mu m) = \frac{\sum nd}{200}$$

where D is the mean of particle size, d is the diameter of the particle and n is the number of particles present in diameter d.

Entrapment efficiency of tramadol hydrochloride

The amount of tramadol hydrochloride encapsulated in the microspheres was determined using the formula (11):

$$E\% = \frac{Q_p\ (mg)}{Q_t\ (mg)} \times 100$$

where E is the entrapment efficiency, Qp is the quantity of drug encapsulated in microspheres, Qt is the total drug added for encapsulation.

The drug content of microspheres was

determined by dissolving a known weight of microparticles before the cross-linking process in buffer solution and analyzed after dilution at 270 nm using a UV-VIS spectrophotometer *Specord 210*.

In vitro drug release from microspheres

The *in vitro* release studies of various tramadol hydrochloride micro particles was determined using USP apparatus II (Erweka) at 37 °C ± 0.5 °C. Each sample of microspheres, equivalent to 100 mg of tramadol hydrochloride, was added to 500 ml of dissolution medium. The dissolution medium was kept at pH 1.2 for 2 hours, pH 4.5 for 2 hours and pH 7.4 for the next 8 hours. Ten millimeters of sample were withdrawn at regular time intervals and the same volume of dissolution medium was replaced. After suitable dilution, the tramadol hydrochloride content was estimated at 270 nm using a UV-VIS spectrophotometer (*Specord 210*) (12).

Drug release kinetics

The obtained experimental data from *in vitro* release studies were fitted to various kinetic equations. Knowledge of the kinetics of drug release from microspheres is important for the *in vivo-in vitro* correlation. The applied kinetic models are: zero-order ($F= k_0 \cdot t$; k_0= the zero-order release constant), first-order ($F=100 \cdot (1-Exp(-k_1 \cdot t))$; k_1= the zero-order release constant), Higuchi ($F=kH \cdot t^{0.5}$; kH= the Higuchi release constant), Korsmeyer-Peppas ($F= kKP \cdot t^n$; kKP= the release constant incorporating structural and geometric characteristics of the drug-dosage form; n= the diffusion exponent indicating the drug-release mechanism) and Hopfenberg equation ($F=100 \cdot (1-(1-kHB \cdot t)^n)$; kHB= the combined constant of the release process which considers both the erosion rate constant and the initial concentration of drug in the matrix)(13).

RESULTS AND DISCUSSION

Gelatin microspheres loaded with tramadol hydrochloride in the form of a white powder are characterized by a free flow. Observed under the microscope, they appear in the form of spherical particles.

Product yield

The obtained results indicated that as the stirring rate increased the percentage yield decreased, which indicated a loss of material due to high speed stirring. The results are shown in first table.

TABLE I
The effect of the stirring rate on product yield

Stirring speed (rpm)	Product Yield (%)
300	94,92 ± 2.24
500	90,93 ± 2.09
600	66,71 ± 3.01

All mean values are obtained by 3 readings (± SD)

Particle size analysis

The size distribution of microspheres was between 80 and 500 μm, with an average size of 190 μm (fig. 1). Gelatin microspheres loaded with tramadol hydrochloride were separated into two classes with different particle sizes, one with particles ranging from 80 to 250 μm, and another 250-500 μm. For future studies three classes of microspheres were used, different in terms of granulometry and noted: MT80-250, MT250-500, MT80-500, respectively. Formula MT80-500 consisted in not separated particles while the others two were obtained separating particles by size.

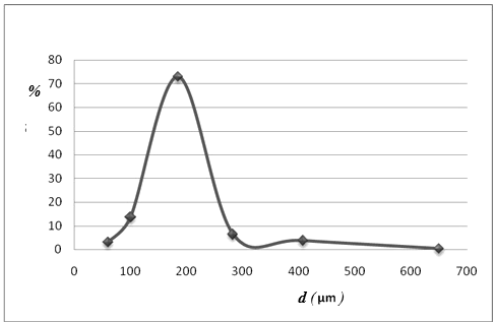

Fig. 1. Particle size distribution of microspheres loaded with tramadol hydrochloride

Entrapment efficiency of tramadol hydrochloride

The entrapment efficiency was 67.56, 79.91, 70.03% for formulations MT80-250, MT250-500 and MT80-500. As the microsphere size was increased, the entrapment efficiency increased. High entrapment efficiency was observed for MT250-500 formulation, and the lowest for MT80-250 formulation, this indicating that, during the preparation process, higher parts of drug was removed from the small particles than from the largest ones, the smaller being the particles, the higher being their exposed surface areas.

In vitro drug release from microspheres

We studied the influence of particle size on tramadol release from the microspheres. The release studies showed acceptable profile for an extended release of tramadol from cross-linked gelatin microspheres. The release rate of tramadol is shown in fig. 2 (Values represent a mean of six determinations and bars represent ± SE).

The release was biphasic with an initial higher rate of release; after the release it became slow and prolonged. The cumulative percentages of drug release after 12 hours were found to be 96.02%, 61.29% and 82.34% for formulations MT80-250, MT250-500 and MT80-500. The drug release rate was faster from MT80-250 microspheres when compared with higher particle formulations.

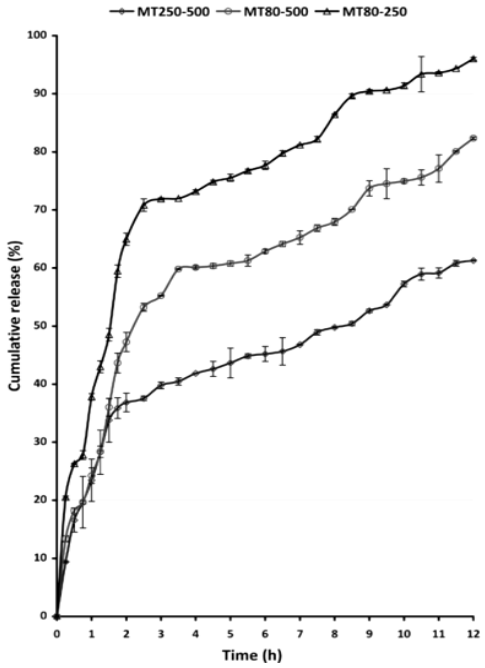

Fig. 2. The *in vitro* release of tramadol hydrochloride from gelatin microspheres

Although entrapment efficiency is directly proportional to particle size, the release rate of tramadol has been shown to be inversely proportional to particle size, due to greater surface contact with the dissolution medium.

Drug release kinetics

The models by which the release profiles were fitted in order to analyze the kinetics of tramadol release from studied formulations are shown in table II.

To discriminate between the kinetic models we used the AIC index (Akaike

Information Criterion). Considering that the lowest values indicate the best fitting, from the comparative analysis (fig. 3), it appears that for both periods (0-2 h and 2-12 h, respectively) tramadol release from the microspheres can be described by the Korsmayer-Peppas kinetic. This kinetic model is based on Fick's diffusion laws.

TABLE II
Kinetics of tramadol released from microspheres

Kinetic Models		zero-order	first-order	Higuchi	Korsmeyer-Peppas		Hopfenberg	
Kinetic Parameters		k_0	k_1	kH	kKP	n	kHB	n
Time: 0 – 2 h:								
Formula Code	**MT 250-500**	21.2	0.26	25.4	24.4	0.64	0.000	635.9
	MT 80-500	24.4	0.30	29.0	26.8	0.76	0.013	23.8
	MT 80-250	34.3	0.49	40.9	38.9	0.68	0.001	351.9
Time: 2 - 12 h								
Formula Code	**MT 250-500**	6.2	0.09	18.4	26.8	0.31	0.000	630.0
	MT 80-500	8.4	0.17	25.1	39.8	0.27	0.000	2393.1
	MT 80-250	10.3	0.32	31.0	54.3	0.22	0.000	2913.9

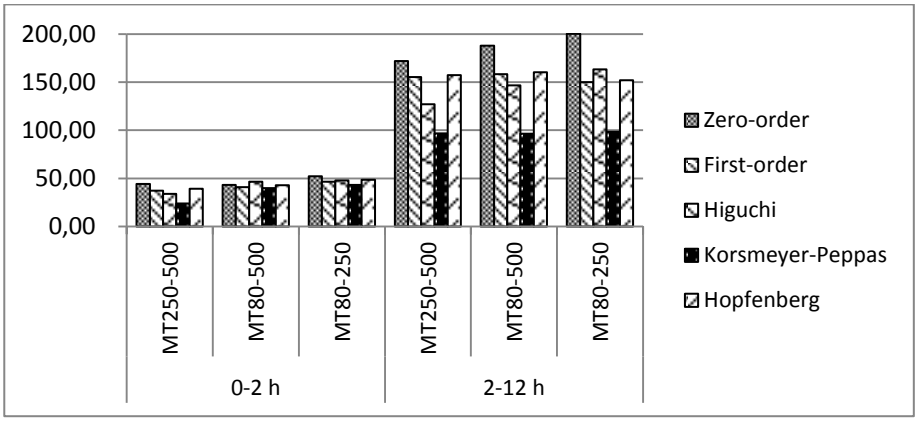

Fig. 3. AIC index values

To determine the mechanism of the kinetic processes by which the tramadol is released from the studied formulations, the *in vitro* release profiles were fitted to the Korsmeyer-Peppas model, determining the diffusion exponent 'n' and the kinetic con-

stant 'kKP' (h^{-1}). Each of the three studied profiles was subjected to the kinetic equation for the determined data over the period during which the maximum of 60% of the initial content was released (i.e.: 11.0 hours in case of MT250-500; 3.5 hours in case of MT80-500; 1.75 hours in case of MT80-250). In addition to the simple kinetic equation, we also applied two variants of the model: the equation with "T_{lag}" (h) which includes the time lag until the expression of the kinetic process; and the equation with "F_0" (%) which considers the fraction of drug that is suddenly released at the start of the kinetic process. The degree of fitting is shown by parameter values 'Rsqr_adj' (the adjusted coefficient of determination), 'MSE' (the mean square error), 'AIC' (the Akaike Information Criterion) and 'MSC' (the Model Selection Criterion) (13).The results are presented in table III.

'Rsqr_adj' parameter values (0.9616 - 0.9756) show that the kinetic model does not fully represent the factors influencing the kinetic processes, but, overall, all "Goodness of Fit" parameters show comparable kinetic processes without significant differences between the analyzed *in vitro* release profiles. In all cases, the resulting kinetic processes happen without any initial high drug quantities released (F = 0.00). The values of n = 0.65 (MT80-500) and 0.63 (MT80-250) indicate mechanisms of the releasing processes by non-Fickian (abnormal) diffusions ($0.5 < n < 1$) and the value of n = 0.34 (MT250-500) indicates a release mechanism in which diffusion does not represent the limiting process for the release kinetic ($n < 0.5$). In the latter case, a relatively short lag time occurs in the release kinetics (≈ 15 minutes) before the onset of the kinetic process.

CONCLUSIONS

Tramadol hydrochloride loaded gelatin microspheres were formulated for extended release of drug after oral administration. Using a micro particulate drug delivery system with different sizes of particles can

ensure a more or less extended release of the drug. The formulated microspheres could prolong the drug release up to 12 hours.

Among the different formulations prepared in this study, M80-250 showed a better release profile, but for a more prolonged effect it can use the other two formulations.

The Korsmeyer-Peppas equation was found to be the best kinetic model to describe the release kinetics of tramadol from the microspheres.

ANALYSIS OF PROGNOSTIC FACTORS IN COLORECTAL CARCINOMA (Abstract): Colorectal cancer is one of the most common malignancies in development countries. The purpose of this study was to analyze the epidemiologic profiles of the disease, to examine the results of survival at five years after diagnosis and how it was influenced by pathological aspects. **Material and methods**: In collaboration with Oncologic Clinic all colorectal cancer diagnosed from January 2002 to December 2006 were included in the study. Medical records of patients were retrieved and we note: age, residence, diagnosis date, grade, and stage and histology variables. Then were analyzed prognosis and survival at 5 years of patients related to these parameters. **Results**: A total of 238 patients with colorectal cancer were identified. The average age at diagnosis was 63.3 years and more than half of cases were men (59%). By the end of the follow-up period 103 patients had died, 66.1% of them representing colon cancer. When analyzing the survival length according to tumor location at the end of the study, we found that are no significant differences between survivals in colic tumors compared to the rectum – 53.9 months for right colon, 51.4 months for left colon and 49.5 months for rectum. The majority of tumors were grade II moderately-differentiated tumors 48.7% (116 of cases), and patients with grade I had the best survival, on average of 84.52 months. Tubular forms of colorectal cancer had the best percentage of five years survival (55.81%) being also the highest rate of survival (45.24% months).**Conclusion:** Factors that contribute to a favorable prognosis in colorectal cancer are tubular microscopic form, disease diagnosed in TNM stage I and II, GI and GII grading. **Keywords:** COLORECTAL CANCER, ADEN CARCINOMA, PROGNOSTIC FACTORS.

Colorectal cancer is one of the most commonly diagnosed cancers worldwide with over 1.2 million new cancer cases and 608700 deaths estimated to occur annually. According to the last global onco-epidemiological analysis it is the second most common cancer among women, and the third most common cancer among men (1, 2).

In Romania, colorectal cancer is the most common gastrointestinal malignancy, representing the third leading cause of cancer death after lung and breast cancer. The highest incidence of colorectal cancer is in patients pertaining to the 60-69 years age group. Since in Romania, based on demographic studies, the population above 65 years old will double in the next 50 years, we have considered a more detailed analysis of the factors then can influence the development of complications and occurrence of postoperative deaths in patients

older than 80 years old that are operated on for colorectal cancer to be useful (3).

New research about colorectal cancer is determined by the continuous increase of disease incidence both undeveloped countries that already register high levels of prevalence, and in countries where colorectal cancer incidence was not regarded as a matter of concern. The increase in incidence of colorectal cancer in Romania and also in Eastern Europe countries could be attributed to lifestyle changes, presumably introduced by westernization, resulting in obesity and physical inactivity (4).

As in any neoplastic disease, the tumor stage remains to be the most important factor of prognosis in colorectal cancer and iti is the basis for the authoritative patient management guidelines that influence most patient management decision. The International Union Against Cancer (UICC)/ American Joint Committee on Cancer (AJCC) TNM classification system is the principal staging systems utilized and therapeutic decisions are most often based on this classification system (5). Great changes in the TNM staging system for colorectal cancer have occurred from the 5th edition to the 7th edition, particularly regarding the pN classification.

The diagnosis and early detection of colorectal carcinoma is one of the major goals and should become a priority for the health system. Colorectal cancer recognizes a natural evolution compatible with a long asymptomatic period, generally estimated to last over five years. This period corresponds to early stage of cancer transformation of adenomatous polyps to cancer and invasion beyond the basement membrane. A significant number of patients with colorectal carcinoma who undergo apparently curative surgery develop local recurrence or distant metastases, leading to shorter survival rate of survival.

The prognosis of colorectal carcinoma patients involves many factors such as histological type of cancer, size, location, degree of tumor invasion, loco regional metastases, and in other organs (6). Although treatments for colorectal carcinoma have developed rapidly in recent years, colorectal cancer still remains the second common cause of cancer – related death. To improve colorectal cancer prognosis, fundamental research in genetics and molecular biology and colorectal screening with the widespread practice of noninvasive techniques (virtual colonoscopy) are some new relatively new directions to be developed (7).

MATERIAL AND METHODS

The study registered 238 patients who were diagnosed with colorectal cancer hospitalized in the Filantropia Hospital of Craiova from January 2002 until December 2006. We performed this study in collaboration with the Oncology Clinic in order to identify cases of colorectal cancer, to describe the epidemiologic profiles of the disease, to examine the results of survival at five years after diagnosis and how it was influenced by pathological aspects. Processed data are from case report forms. Data on survival June 1st, 2012 – when the patients follow-up – were from the Registry of Civil Status of Craiova.

Data collection

Medical records of the 238 patients were retrieved and the following information abstracted: age, residence, diagnose date, grade, stage, topology, histology variables and treatments. There were analyzed prognosis and survival of patients examined in the batch related to these parameters. Preoperatively patients from the study

were investigated by colonoscopy. Histopathological reports were reviewed to delineate the main citopathologic features, sub- site affection, the presence of any predisposing pathology and disease stage.

In the medical records of patients were found six types of surgery: colectomy for transverse colon with colo-colic anastomosis, subtotal colectomy with ileo/colo/rectal anastomosis, amputation of the rectum, and right hemicolectomy with ileo-transverese anastomosis ileo/colo/rectal, rectosigmoidectomy resection with colo-recto anastomosis and left hemicolectomy with colorecto/colo anastomosis.

Data processing and analysis

The main statistical analysis software packages were Microsoft Excel 2003 and Epi Info 2000. The 5-years overall and specific survival rates were estimated using the Kaplan-Meier method and the differences between the categories of each variable were assessed using log-rank test.

Ethical considerations

Permissions were obtained from Filantropia Hospital of Craiova as well as from the authorities of the included hospitals after approval of the study protocol and data compilation form. Data confidentiality was maintained all through the study.

The main goals for this study were:

- to identify cases of colorectal cancer;
- to describe the epidemiologic profiles of the disease;
- to examine the results of survival at five years after diagnosis and how it was influence by location and pathological aspect.

RESULTS

A total of 238 cases of colorectal cancer were included in registry from January 2002 to December 2006 and 103 patients of these are diseased. The distribution by sex, through the studied period, shows the predominance of male (59%), giving a male: female of 1.4:1.

Patients designated as residing in an urban area constituted 63% of all patients and distribution by area of origin is urban/rural = 1.70. In any given year, between 37and 60 new cases of colorectal carcinoma were included in registry. Age and tumor site distribution of cases showed that 7.4% of all cases were under the age of 40. The age distribution showed limits ranging between 29 and 82 years with an average of 63.3 years. The maximum age incidence is between 58-74 years. Report colic cancer/rectal cancer was 161/77 = 2.19.

For an effective and comparative analysis of clinical features, treatment and prognosis in colorectal cancer, the large bowel was divided based on embryological, anatomical, clinical, pathogenesis and therapy in three segments: right colon (I) until the splenic angle, left colon (II) until the rectosigmoid junction and rectum (III) (8). According to this, the location of colorectal cancer was: right colon 34 cases (14.3%), left colon 127cases (53.4%) and rectum 77 cases (32.3%).

The vast majority of patients did not present polyps 234 (98.3%), though of the 4 patients who had polyps, 75% were over the age 40. Adenocarcinoma was the most common histopathology type of tumors 198 (91.2%)

The majority of tumors were grade II moderately-differentiated tumors 48.7% (116 of cases), followed by 23.9% (57 cases) grade III, 15.5% (37 cases) grade I and 11.8% (28 cases) grade IV. The degree of differentiation of colorectal adenocarcinoma showed a large number of patients

alive with G1 (86.48%), followed by those with G2 (61.20%), G3 (35.08%) and G4 (7.14%). Patients with G1 had the best survival, on average of 84.52 months, followed by those with G2 with an average of 59.21 months, G3 (31.34 months) and G4 (3.86 months).

TNM staging of the study group revealed 41 patients in stage I (17.2%), 86 patients in stage II (36.1%), 83 patients in stage III (34.9%) and 28 cases in stage IV (11.8%). Positive nodes were identified in 89 patients with stage III and IV, as follows: stage III - N1-47 cases and N2-36 cases; stage IV – N1-17 cases and N2- 34 cases. Metastatic colorectal cancer was diagnosed in 11.8% of cases, mostly involved peritoneum and liver.

Surgeries were performed on 217 patients. They practiced all six types of surgery listed above: colectomy for transverse colon with colo-colic anastomosis 29 cases, subtotal colectomy with ileo/colo/rectal anastomosis 19 cases, amputation of the rectum 79 cases, right hemicolectomy with ileo-transverese anastomosis ileo/colo/rectal 34 cases, recto-sigmoidectomy resection with colo-recto anastomosis 47 cases and left hemicolectomy with colo-recto/colo anastomosis 42 cases.

DISCUSSION

Colorectal cancer mortality in Romania has followed a steady increase from 14‰ to 18.3‰ for men and women in the years 1960-1990 to about 22.2‰ in 1995-2003 and decreased slightly to 19.2‰ in 2008, after the last statistical EU statistics (9). Following trends in incidence, mortality because of colorectal cancer is much higher in urban areas, without a tendency to change from one year to another.

Numbers of new cases of colorectal cancer detected are variable from one year to another, but with a growing medium and long term, despite the fact that the people of Romania that represent these patients decreases. In other words, the incidence of this cancer is increasing in our country, this fact is evidenced by a study carried out, estimating that this trend of increasing incidence will occur at least until they reach the values reported by industrialized countries. Increasing incidence of colorectal carcinoma associated with increase in both prevalence and mortality of this disease, suggests that current methods of treatment, only few cases are actually curable, with a tendency to heal (cytological forms a good degree of differentiations, in an early stage), the rest is just temporary and/or limited interventions (several months to several years) due to extension of neoplasic disease.

Results of a European study show that survival at five years in patients with colorectal cancer as a whole is especially influenced by stage and the factors that are directly or indirectly related to the primary tumor. Thus, these prognostic factors that should be considered in assessing the survival and follow-up are: stage, grading and adenopathy (10).

We note an increase in the number of cases from year to year. Thus, in 2002 there were 37 cases diagnosed, in 2003 their number increased to 41 cases, in 2004 we identify 47 cases, 53 cases in 2005 and 60 cases in 2006. The distribution by sex, giving a male: female of 1.4:1. This change in the M/F ratio is not statistically significant, although there are European studies that confirm the increased incidence of malignancies in women in particular.

In agreement with other studies (11, 12), survival rates were significantly higher in women. This association has been attributed to many underlying factors, such

as access to care, sex-specific co morbidities treatment disparities and hormonal status. The CONCORD study observed that in most countries, survival was better in patients with colon cancers than in those with rectal cancers (12). The association found between an excess risk of death and some clinical factors is consisted with the results of previous studies. Advanced stage at diagnosis (13), undifferentiated/poorly differentiated tumors (14) are factors that well known and described in the literature.

According to the present study the average at diagnosis of was 63.3 years. When compared with the reports from developed countries (15, 16), the mean age at diagnosis of colorectal cancer is lower in the Kingdom. In England, some researchers reported that between 1996 and 2004 the mean age at diagnosis of colorectal carcinoma was 68.4 years in men and 69.0 years in women (17). In Australia, the median age at diagnosis of colorectal cancer in 2008 was reported to be 70.0 years (18), similar to that is reported in the United States (19) and Sweden (20).

Since Dukes classification, all classification system of colorectal cancer were the most important predictor of survival, determining prognosis is the reason why they were created. The most used and reliable classification system is the system adopted by the AJCC TNM (American Joint Committee on Cancer) and UICC (International Union Against Cancer) (21). Undoubtedly, the most important prognostic factors for survival are the extent of tumor invasion into the wall and the presence of metastases in regional lymph nodes-the stage in which colorectal cancer was diagnosed (22). Obviously, the more advanced the stage of the cancer of the colon or rectum is, the more the life expectancy is less (23).

According to stage, patients that are still alive had a median survival of 73.61 months for stage I, 54.13 months for stage II, 43.6 months for stage III and 9.21 months for stage IV. Wilcoxon test showed the same high statistical significance differences between stage, with a p-value of less than 0.0001 (Fig. 1).

According to the TNM classification (24) pT4 is the most advanced stage of local tumor development in colorectal cancer, including both direct tumor invasion of adjacent structures (pT4) and invasion of visceral peritoneum with invasion of adjacent structures (pT4) including here free perforation into the peritoneal cavity. The most important and damaging to prognosis characteristics of colorectal tumor failing in T4 is the serous as a separate anatomopathological variable demonstrated in the multivariate analysis that this is an independent negative prognostic factor (25). In our study we find 28 patients in stage IV, 11 patients with peritoneal metastases and 19 with hepatic metastases.

When analyzing the survival length according to tumor location at the end of the study, we found that are no significant differences between survivals in colic tumors compared to the rectum – 53.9 months for right colon, 51.4 months for left colon and 49.5 months for rectum. Kaplan-Meier curves showed no significantly higher survival rated for colon compared to the rectum (fig. 2).

Gross pathological form is a parameter in formulating prognosis, tumor appearance reflecting its biological nature. Exofitic or polipoid tumor patients seem to have a better prognosis than those with ulcerated or infiltrative tumor. In our study macroscopic aspects of excision parts showed the following: infiltrative-48 cases (22.1%), ulcerative–35 cases (16.1%), vegetant–32 cases (14.7%), ulcerative and vegetant–56

cases (25.8%), infiltrative and ulcerated–21 cases (9.7 cases), infiltrating and vegetant–13 cases (6.0%), vegetant – infiltrative - ulcerated–21 cases (5.5%).

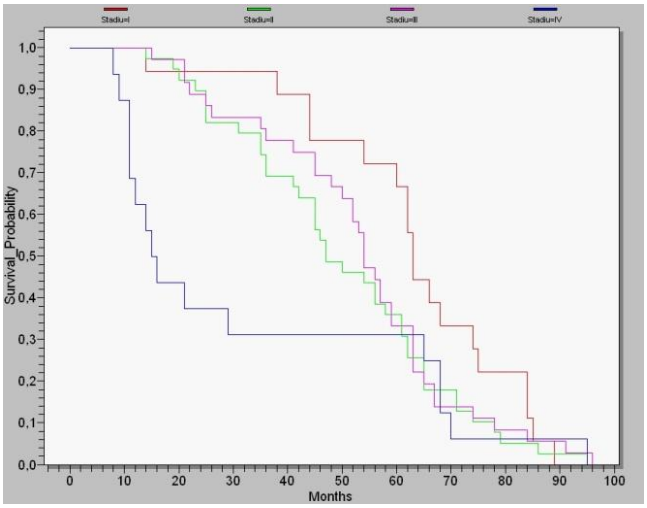

Fig. 1. Survival on July 1st 2010 according to CRC TNM stage

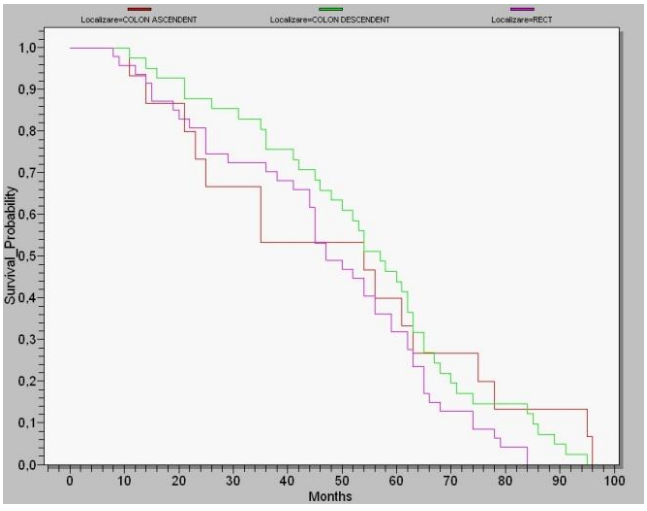

Fig. 2. Kaplan-Meier survival curves and CRC location

Concerning the microscopic examination, the highest percentage of patients alive was recorded in tubular forms (55.81%), followed by papillary forms (46.55%), rare/particular (45.83%) and mucinous (31.42%). In terms of number of cases tubular colorectal cancer had the best percentage of five years survival (55.81%) and longest higher survival (45.24%). Kaplan-Meier curves showed significantly higher survival rates for mucinous compared to tubular forms (Fig. 3).

Colon cancer, as well as rectal cancer treatment, changed over time, in our study adjuvant chemotherapy was administered

to 138 (85.71%) of patients with colon cancer and 56 (72.72%) with rectal cancer. By the end of follow-up, 103 patients had died: 68 deaths (66.1%) were due specifically to colon neoplasm and 35 (33.9%) were to rectal cancer (Fig. 4).

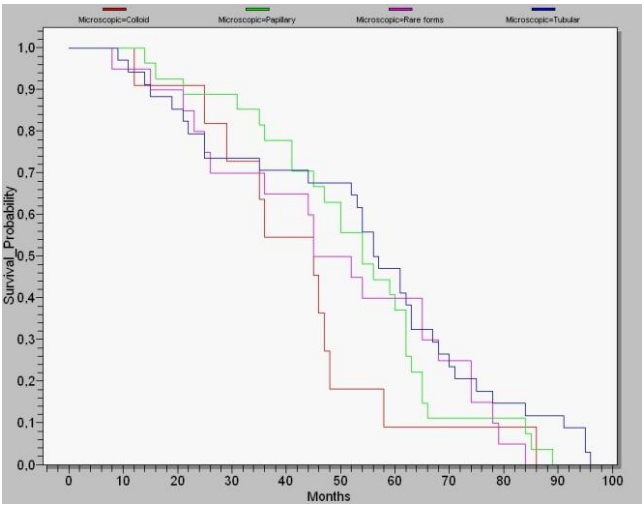

Fig. 3. Kaplan-Meier survival curves and CRC microscopic aspects

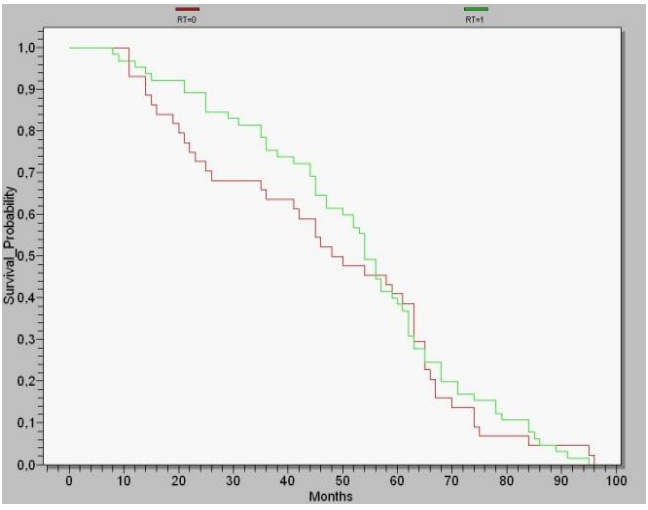

Fig. 4. Kaplan-Meier survival curves and CRC adjuvant therapy

Evaluating lymph node metastasis has become a prognostic factor for CRC, and LNR is an important component of staging. LNR has also been identified as being of significant prognostic value in breast and gastric cancer. Berger et al were the first to suggest LNR as an important prognostic factor after curative resection for CRC. It was then established as a powerful independent index of CRC that reflected the probability of positive lymph nodes based on the number of retrieved lymph nodes.

The total number of lymph-nodes resected was not found to be a significant predictor of survival under univariate analysis (P=0.44), survival for patients grades N1 and N2 was 32.3% and 43.5% at 5- years respectively (Fig. 5).

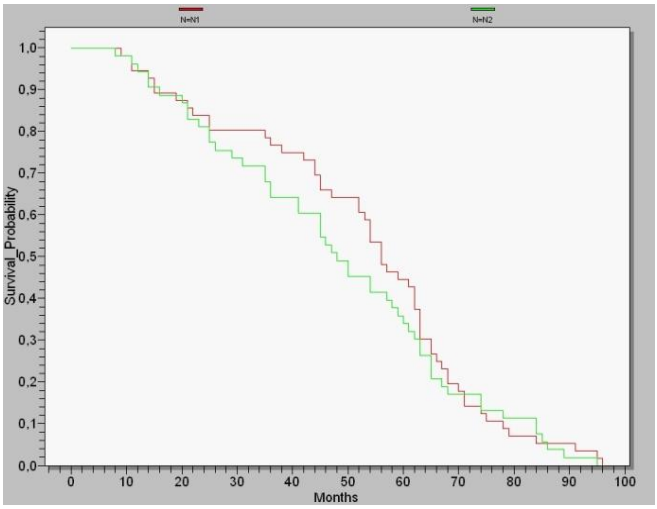

Fig. 5. Kaplan-Meier survival curve for node-positive patients stratified by N stage

CONCLUSIONS

Colorectal cancer recognizes a natural evolution compatible with a long asymptomatic with a long asymptomatic period, generally estimated to last over five years. The introduction of new techniques for screening the population, the increasing educational level of the population, the use of recent advances in laparoscopic surgery and oncology management, properly improved the result. Factors that contribute to a favorable prognosis in colorectal cancer are tubular microscopic form, disease diagnosed in TNM stage I and II, GI and GII grading.

Using routinely collected data, at no inconvenience to patients, we have identified some important areas relating to early deaths from colorectal cancer, which merit further research.

THE EVALUATION OF PREOPERATIVE NUTRITIONAL STATUS IN PATIENTS UNDERGOING THORACIC SURGERY. **Aim.** The aim of this study was to assess the preoperative nutritional status of patients undergoing thoracic surgery using different nutritional tools. **Material and methods.** We conducted a prospective study on a sample of 43 thoracic patients, including 23 with neoplasms and 20 with non-neoplastic pathology who underwent thoracic surgery procedures between July-September 2011, in the Thoracic Surgery Clinic in Iaşi. Weight and height were measured and body mass index (BMI) was calculated. WHO classification for BMI categories was used. Preoperative serum level of transthyretin (TTR) and demographic data (gender, age) were also assessed. All patients were examined by the Subjective Global Assessment (SGA) and the Nutritional Risk Screening 2002 (NRS 2002). **Results.** After performing SGA, 67.9 % of the patients were well-nourished, 21.4 % were moderately or suspected of being malnourished and 10.7 % were severely malnourished. The level of TTR was significantly lower in the moderately or severely malnourished group, compared to those considered well-nourished. According to NRS-2002, 42.9 % of the patients were considered at nutritional risk. The level of TTR of these patients was lower than the level of TTR of the patients without nutritional risk, but without statistical significance. **Conclusions.** Subjective Global Assessment (SGA) and the Nutritional Risk Screening 2002 (NRS 2002) are useful in identifying patients with nutritional risk, so that appropriate nutritional management could be initialised even before surgery. **Keywords:** PREOPERATIVE STATUS, NUTRITIONAL STATUS, THORACIC SURGERY, TRANSTHYRETIN

The prevalence of malnutrition in surgical services varies between 20-50% (1). Preoperative malnutrition is common in surgical patients and has been associated with adverse clinical outcomes (2). This suggests that identifying patients at risk and recommending perioperative nutritional support can improve nutritional status of patients undergoing surgery. Hospital malnutrition has serious adverse effects on the treatment and outcome of illness and is associated with higher infection and complication rates, increased muscle loss, impaired wound healing, longer length of hospital stay and increased morbidity and mortality (2, 3). Costs are increased in

malnourished patients whether or not a complication occurs, but they augment significantly if one happens (4). All of these factors contribute to increasing length of hospitalization, number of re-admissions in the hospital and a marked increase in patient care costs (5).

Protein-energy malnutrition is associated with a worse prognosis and increased mortality. Although several screening systems have been developed, it is still poorly recognized, and there is no consensus on which test is more reliable and feasible in clinical practice. Transthyretin (TTR) is a potential useful marker because its serum concentrations are closely related to early changes in nutritional status (6). Nutritional status is largely not systematically assessed and therefore the patient's nutritional plan is not yet included in the usually medical plan. There is a lack of data on the perioperative nutritional risk and on the prevalence of perioperative malnutrition in thoracic surgery units. The aim of this study was to assess the nutritional status of patients undergoing thoracic surgery using different nutritional tools.

MATERIAL AND METHODS

The study took place in Thoracic Surgery Department in Clinical Pneumology Hospital, Iaşi, Romania. In this prospective study, we enrolled all consecutive patients who underwent thoracic surgery between July-September 2011. The Ethics Committee of the Clinical Hospital of Pneumology Iaşi approved the study (no. 13953/2011), which was conducted in accordance with the Helsinki Declaration and all patients signed informed consent form before being enrolled. The demographic data (gender, age) of patients were assessed. We evaluated weight, height and thus calculated body mass index (BMI). All anthropometric measurements were performed by the same investigator. The weight was recorded *a jeun*, to the nearest 0.1 kg, using calibrated medical portable scales with 4 sensors (model 27236; Liamed, Brasov, Romanian). Height was measured using a stadiometer to the nearest 0.1 m (Practical Metrology, Lancing, UK). The BMI was calculated by the current weight (kg) over height $(H)^2$ (m^2) ratio and classified according to World Health Organization. Subjects were grouped in well-nourished (BMI $\geq$ 18.50 kg/m^2) and malnourished (BMI $<$ 18.50 kg/m^2) patients. Preoperative serum level of TTR was analysed by ELISA. All patients were examined by the Subjective Global Assessment (SGA) and the Nutritional Risk Screening 2002 (NRS 2002). SGA was carried out based on patient's history regarding weight loss, dietary intake, gastrointestinal symptoms, functional capacity, and physical signs of malnutrition (loss of subcutaneous fat or muscle mass, oedema, ascites), according to the method described by Detsky et al. (7). Patients were classified as well-nourished (A), moderately or suspected of being malnourished (B) or severely malnourished (C). The Nutritional Risk Score (NRS-2002) is the recommended screening tool (for nutritional risk) by the European Society of Parenteral and Enteral Nutrition/European Society of Clinical Nutrition and Metabolism (ESPEN) and was performed according to the recommendations set by Kondrup et al. (8). Nutritional risk was evaluated through impaired nutritional status and disease severity. Evaluated nutritional parameters were: BMI, recent weight loss, and food intake during the week before admission. The worst indicator was taken into account. Patients were scored in each of the two components: undernutrition and disease severity. A score between 0 and 3 was given for each of the two components according to the recommendations for each

parameter. When the age of the patient was>70 years, a value of one was added to the total score. Patients with a total score of three or more were considered at nutritional risk. The results of the study were expressed as mean ± standard deviation (x±SD). Unpaired t-tests were used to compare data in different groups of patients. Statistical significance was set at $p \leq 0.05$ for all tests.

RESULTS

Forty three patients who underwent thoracic surgery were included in this study (tab. I). Subjects had a median age of 54.51 ± 16.70 years and 79 % (n=33) were male. The average BMI in the study group was 24.14 ± 5.44 kg/m^2, the women having an average BMI of 25.25 ± 5.32 kg/m^2, and the men with an average BMI of 23.72 ± 5.35 kg/m^2 ($p>0.05$).

Analysing BMI, we noticed that 13.8 % of the subjects had a BMI < 18.5 %, the others being: 44.8 % of normal weight, 24.1 % overweight and 17.2 % obese. The average TTR level in the study group was 20.8 ± 8.9 mg/dl, and there was no statistically significant difference between the TTR of patients with BMI < 18.5 kg/m^2 (TTR = 19.2 ± 8 mg/dl) and those with BMI ≥ 18.5 kg/m^2 (TTR = 21.1 ± 9.2 mg/dl).

TABLE I

Distribution of series of 43 thoracic patients according to pathology

Pathology		**N**	**%**
Neoplastic	NSCLC	17	39,53
	SCLC	1	2,32
	Esophageal squamous cell carcinoma	1	2,32
	Breast Cancer with malignant pleural effusion	1	2,32
	Basal cell cancer of central face with malignant pleural effusion	1	2,32
	Cancer with no clear origin and malignant pleural effusion	2	4,65
Non-neoplastic	Spontaneous pneumothorax	4	9,30
	Pleural empyema	4	9,30
	Sarcoidosis	2	4,65
	Pulmonary tuberculoma	2	4,65
	Tuberculous thoracic parietal abcess	1	2,32
	Pulmonary abcess	1	2,32
	Posttraumatic pneumothorax	1	2,32
	Posttraumatic hemopneumothorax	1	2,32
	Spontaneous chest wall hematoma	1	2,32
	Miastenia gravis with thymus hyperplasia	1	2,32
	Pulmonary hamatochondroma	1	2,32
	Costal osteoid osteoma	1	2,32

NSCLC - non-small cell lung cancer; SCLC - small cell lung cancer

After performing SGA, we concluded that 67.9 % of the patients were well-nourished (score A), 21.4 % were moderately or suspected of being malnourished (score B) and 10.7 % were severely malnourished (score C). When taking into account only patients with a BMI ≥ 18.5 kg/m^2, we still found that 25 % were in the categories with risk, that is: 20.8 % were moderately or suspected of being malnourished (score B) and 4.2 % were severely malnourished (score C). The level of TTR was significant-

ly lower in the group with scores B or C according to SGA, compared to those considered well-nourished (TTR = 15.5 ± 7 mg/dl vs. TTR = 23.1 ± 8.9 mg/dl, p=0.05).

The Nutritional Risk Score (NRS-2002) showed that 42.9 % of the patients included in our study were considered at nutritional risk. Moreover, out the patients with a BMI ≥ 18.5 kg/m^2, 37.5 % were at nutritional risk, based on the NRS-2002. The level of TTR of the patients considered at nutritional risk was lower than the level of TTR of the patients without nutritional risk, but statistical significance was not obtained (TTR = 17.9 ± 6.9 mg/dl vs. TTR = 23 ± 9.8 mg/dl, p>0.05).

DISCUSSION

Protein-energy malnutrition represents acute or chronic protein loss leading to a state of nutritional deficiency that causes a decrease in defense mechanisms against infection, delay healing and alteration of certain important functions (respiratory, cardiac, endocrine). It is associated with a lower response of the organism during a certain condition and may be reversed in an anabolic state by medical intervention. It is common in hospitalized patients, being associated with increased mortality (9).

Disease-related malnutrition varies in different studies and has been reported in 10% to 55% of people in hospital and the community (2). The prevalence of malnutrition in people with cancer, chronic diseases and after major surgery has been reported to be around 10% (2). A large percentage of our study population had or was at risk of malnutrition.

There is no "gold standard" for determining nutritional status. A modification of protein and energy intake leads to changes in the same direction of circulating concentrations of TTR (10). Like albumin, TTR is considered a negative acute phase reactant, as it may decrease in an inflammatory context (11).

Currently TTR is the most commonly used visceral protein to assess nutritional status (12). TTR is a useful marker in monitoring malnourished patients because its serum concentrations are influenced by changes of early nutritional status and respond to nutritional support (13). TTR level measurement is a sensitive and cost-effective method for assessing the severity of disease in critically or chronically ill patients (14).

TTR is a more reliable nutritional marker than albumin due to short half-life (48 hours), a relatively low spread in the body and the rapid synthesis which is influenced by protein intake (15). TTR concentration decreases significantly in just three days after inadequate nutritional intake and increases by 1 mg/day when the nutritional requirements are satisfied (16). Hypoalbuminemia is an independent strong risk factor, depending on the concentration, for morbidity, mortality, acute renal failure and other negative clinical results (17), but due to the widespread in the body, the half-life of 20 days, and sensitivity to the patient's hydration status, albumin is a less sensitive parameter in assessing protein-energy malnutrition. A study on 1760 patients demonstrated that serum albumin and BMI alone underestimated the prevalence of malnutrition at hospital admission (18).

TTR concentration decreases in the presence of inflammation (negative acute phase reactant). Rapid changes in C-reactive protein may lead to overestimation of malnutrition. While these limitations must be taken into account, the study conducted by Devoto et al. (6) concluded that serum TTR can still be reliable in cases associating inflammatory processes.

SGA is a nutritional score created over two decades ago to assess nutritional status

and risk of infectious complications in patients undergoing surgery. This score takes into account changes in body composition and physiological functions. In one study, patients considered in the category of preoperative severe malnutrition showed higher postoperative infectious and non-infectious morbidity (19). In our study, 32 % of subjects had moderate or severe malnutrition, according to SGA.

In Western Europe, 25-30% of patients who are undergoing surgery are considered at increased nutritional risk preoperatively (20). For nutritional screening in hospitalized patients, the European Society for Clinical Nutrition and Metabolism recommends the use of Nutritional Risk Screening score (NRS 2002). In a general population of hospitalized patients, this score is easy to implement, reliable and reproducible for identifying patients at nutritional risk (8). Compared with other screening tools, this system is unique in that it has been developed from the idea that the indication for nutritional support depends on the severity of malnutrition and increased nutritional needs that may result from underlying disease. Therefore, severe malnutrition or severe disease, alone or together, constitutes an indication for the need for nutritional support (8, 21). NRS 2002 is also used increasingly for preoperative classification and risk assessment (22), although it has been designed to predict therapeutic effects, not complications (8).

A study conducted by Kawai et al. aimed at identifying biomarkers that might be useful in predicting postoperative early recurrence of lung cancer. They evaluated the perioperative nutritional status of the patients by measuring the serum level of TTR and analyzed the correlation between this factor and early recurrence, in a sample of forty-four patients with NSCLC. The conclusion of the authors was that low serum TTR level in the perioperative period was associated with a poorer prognosis in NSCLC patients and could serve as a marker for identifying patients at high risk, even at an early clinical stage. (23).

Devoto et al. studied the prevalence of protein-energy malnutrition and TTR serum concentrations in 108 hospitalized patients. The Detailed Nutritional Assessment (DNA) was used as the reference method to determine protein-energy malnutrition. TTR performance was compared with that of 2 other methods, the Subjective Global Assessment (SGA) and the Prognostic Inflammatory and Nutritional Index score (PINI). According to the DNA reference method, 41% of patients were classified with mild malnutrition and 19% with severe malnutrition. TTR showed the best concordance with the standard DNA method (concordance index, 76.8%) and a good sensitivity/specificity profile (83.1%/76.7%) compared with SGA and PINI. They concluded that TTR could represent a feasible and reliable tool in the evaluation of malnutrition, especially in settings where it is difficult to obtain a more detailed and comprehensive nutritional assessment such as the DNA (6).

CONCLUSIONS

Our data support the assessment of nutritional status of in-patients undergoing thoracic surgery. The nutritional state per se is predictive for postoperative outcome and must be seriously assessed in every thoracic patient undergoing surgery. BMI is not a reliable tool on its own in assessing nutritional status of patients undergoing thoracic surgery. Subjective Global Assessment (SGA) and the Nutritional Risk Screening 2002 (NRS 2002) are useful in identifying patients with nutritional risk, so that appropriate nutritional management could be initialized even before surgery.

RESEARCH STUDIES ON *IN VITRO* AND *EX VIVO* YIELD OF THE MICONAZOLE NITRATE FROM ORAL BIOMUCOADHESIVE TABLETS

2. Discipline of Oro-dental Diagnosis and Gerontostomatology

RESEARCH STUDIES ON *IN VITRO* AND *EX VIVO* YIELD OF THE MICONAZOLE NITRATE FROM ORAL BIOMUCOADHESIVE TABLETS (Abstract): Among the various routes of drug administration, the oral mucosa is perhaps the most often preferred by patients and medical staff. However, oral administration of drugs has disadvantages, which may limit or prevent oral administration of some drugs, especially peptides and proteins, little when they are inserted in special administration systems for the colon. The disaggregation of some oral biomucoadhesive tablets and the *in vitro* yield of the miconazole nitrate was evaluated and in parallel with this, the evaluation of the *in vivo* yield of the antifungal from the pharmaceutical form. Thus, for a clear determination of the oral mucobioadhesive tablets' disintegration with miconazole nitrate, it was necessary to implement a method to simulate the conditions of the oral cavity at a flow of solution (artificial saliva) similar to that of the human one. **Materials and methods:** materials: miconazole nitrate. Methods: The determination of disintegration time according to method A (FRX); the disaggregation of oral biomucoadhesive tablets with miconazole nitrate by means of simulation methods of *in vitro* conditions; the quantitative determination of the miconazole nitrate by means of HPLC method, after the *in vitro* dissolution test; the study of miconazole nitrate's yield in dynamic condition from biomucoadhesive tablets in the presence of artificial saliva (AFNOR). **Results:** The yield profile of the miconazole nitrate in the disintegration solutions by means of classical method from FR X, by HPLC dosage was researched. The release of miconazole nitrate from the oral mucobioadhesive tablets was determined, that varies in time, depending on the type and relation of matrix forming polymers; a low yield speed of the miconazole nitrate from the tablets was determined; the yield profile of miconazole nitrate in disintegration solutions by means of the new suggested method was researched. **Conclusions:** The release of miconazole nitrate from the formulated biomucoadhesive tablets is of swelling and erosion. **Keywords:** MICONAZOLE NITRATE, MUCOBIOADHESIVE TABLETS, *IN VITRO* YIELD.

The influence of some formulation factors on the release of miconazole nitrate from biomucoadhesive oral tablets was studied. Biomucoadhesive oral tablets with miconazole nitrate by the method of direct compression as a result of the completion of the mixture of suitable excipients (sodium carboxymethylcellulose and lutrol 6000 excipients used for the bioadhesion, mannitol used as a sweetening agent and aerosil as lubricant) (1).

The bioadhesive systems ensure an in-

timate contact between the dose and the absorbent tissue, which can lead to high local concentrations and thus a strong flow through the tissue. The efficiency of bioadhesive systems for oral administration of the active substance is influenced by the environment and biological properties of the polymer and of the drug (2, 3).

The researches on bioadhesive administration systems continue at a rapid pace, aiming at an efficient treatment of commonly encountered lesions (sores, ulcers, etc.) of periodontitis, gingivitis and caries. Optimizing the systemic treatment of disease by transmucosal drug administration in the oral cavity continues to be investigated using a variety of dosage forms containing new bioadhesive polymers (4).

Determining the disintegration time of tablets during tests was an old requirement in most pharmacopoeias. Currently, there are severe limitations of the disintegration test, this being applied especially to conventional tablets. The dissolution test was included as a consequence also for other solid forms with extended release. Both the disintegration time and the *in vitro* yield (or the dissolution tests) are determined by official methods (5, 6).

The mucobioadhesive tablets as pharmaceutical form and as a release system of the active substance requires the implementation of a new method of disaggregation method that better simulates the conditions of the oral cavity (7). Thus, for a clearer determination of the oral mucobioadhesive tablets' disintegration with miconazole nitrate it was necessary to implement a new method for determining the flow rate of solution (artificial saliva) similar to that of the human one.

MATERIALS AND METHODS

Materials: Miconazole nitrate (Sigma Aldrich, Germany); *Sodium carboxymethyl cellulose (*Lubrizol, U.S.A); *Mannitol (East Chemical, Weifang City, China) Polyethylene glycol, PEG 6000 microcrystalline powder (*Lutrol,*BASF Pharma, Germany)*; *Aerosil* (Degussa, Germany). All the materials used had the purity degree in conformity with the normatives in force. The miconazole nitrate, the antifungal was used as active substance with 99% purity in oral mucobioadhesive tablets (1) (tab. I).

TABLE I

Formulations of mucobioadhesive tablets with miconazole nitrate

Pharmaceutical substances mg/tablet	Formula I	Formula II	Formula III	Formula IV	Formula V
Miconazole nitrate	25	25	25	25	25
Sodium carboxy methylcellulose (CMC-Na)	20	60	100	100	140
Mannitol	90	90	90	50	30
PEG 6000(Lutrol)	80	40	-	40	20
Aerosil	4	4	4	4	4
Total (mg)	219	219	219	219	219

Methods: 1. The assay of disintegration time according to method A (FRX). For the disintegration of mucobioadhesive tablets with miconazole nitrate one has used 6 bioadhesive tablets from every formulation and as a device. DISINTEGRATION TESTER QC-21 (4). 2.*B. The disintegration of mucobioadhesive tablets with miconazole nitrate by means of simulation method of in vivo conditions*. The equip-

ment used in the disintegration of mucobioadhesive tablets and in the desorption of miconazole nitrate –a personal conception using a burette provided with a dropper, which regulates the artificial saliva flow that goes under dynamic condition on the tested tablet (0.5 mL /minute), an adjustment system of the artificial saliva flow, a support vial of the tablet , a vial for collecting the mixed solution (artificial saliva with active substance), muco-bioadhesive tablets with miconazole nitrate (1 tablet from each formula), 6 porcelain capsules, 10 ml graduated vials, thermostate bath GRANTw6 and artificial saliva solution with pH 7.24 AFNOR (0.26 g of disodium phosphate , 6.7 g sodium chloride, 0,33 g of potassium sulfocyanide, 0.2 g of monopotassium dihydrogen phosphate, potassium chloride 1,2g, sodium bicarbonate 1.5 g, distilled water up to 1000g) .

The human saliva is released into the oral cavity with a flow of 1000mL up to 1500mL/day, resp. 0,5-1mL / minute, a flow rate that is regarded by the equipment. A tablet from each formula was placed in the equipment for the desorption of the miconazole nitrate and the equipment was started so that 0,5mL AFNOR artificial solution per minute falls on the tablet. The tablet is kept in this installation until it totally disintegrates. The artificial saliva solution that has disintegrated the table is being collected every 20 minutes, at a quantity of 10 mL.*3.The quantitative assay of miconazole nitrate by means of HPLC method, after performing the in vitro dissolution test.* The dosage method HPLC was confirmed, which constitutes the objective of this paper, of the miconazole nitrate from oral mucobioadhesive tablets with long yield following the specificity, the exactness (accuracy), the retrieval capacity and also the precision (fig.1).

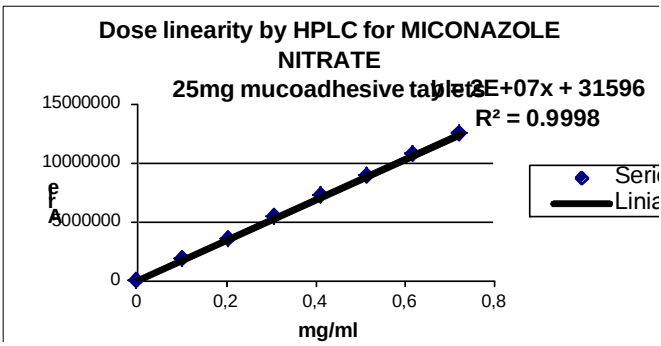

Fig. 1 Calibration curve of the miconazole nitrate by means of HPLC method

The gradual yield of the active substance from mucoadhesive tablets was studied using the current USP dissolution equipment. For the quantitative assay of the antifungal and of the HPLC method's validity one has used an equipment no. 2 (with paddles), dissolution agent respectively phosphate buffer solution to pH = 6.8 (the agent's volume of 500 ml), the rotation speed of 50 revolutions /minute, the temperature of the dissolution agent of 37 ° C $\pm$ 0.5 ° C, a standard solution consisting of 25.0 mg of miconazole nitrate was dissolved in methanol in a 25ml graduated flask. Subsequently, 0.5ml was diluted with 5ml methanol and 5ml phosphate

buffer pH=6.8 in a 10ml graduated flask. 2.5ml of this solution was diluted with phosphate buffer to pH=6.8 in a graduated flask of 10ml (concentration of 0.0125 mg/ml miconazole nitrate). The principle of the method: the dosage of the miconazole nitrate is performed by liquids' chromatography under pressure (HPLC). 4. *The study of miconazole nitrate's yield in dynamic condition from mucobuccal-adhesive tablets in the presence of artificial saliva (AFNOR).* In order to achieve the yield in the miconazole nitrate from oral mucobioadhesive tablets one has used an equipment, which requires the use of as proof of mucobioadhesive tablets with miconazole nitrate dissolved in a solution of artificial saliva AFNOR at pH 7.24 and pure substance, miconazole nitrate, in order to carry out the calibration curves and as an auxiliary system one has used thermostate bath GRANTw6, colorimeter type 252SHERVEDWOOD, spectrophotometer MICROLAB 300- high-performance semiautomatic equipment.

The reagents used for the performance of miconazole nitrate's yield are: reagents for elution from the capsule (0.5ml methanol + 0.5 ml of chloroform), update rate reagent of 10 mL (1,2 dichloroethane), the complexation reaction reagent(solution 0.01M iodine in 1,2-dichloroethane-volume 1mL). Benchmark for spectrophotometer MICROLAB 300: 0.25 mg miconazole nitrate+ 1 mL mixture (chloroform, methanol, 1:1 relation). Over the homogeneous mixture add solution of 1 mL iodine 0.001 M in 1,2 dichloroethane it is brought to a graduaded flask of 10 mL with 1,2-dichloroethane preserving it at 25° C temperature for 50 minutes.

The study of miconazole nitrate's yield under dynamic conditions was approached in order to simulate the almost similar conditions of the oral cavity. The study under dynamic conditions was carried out based on the traditional methodology in the literature, at a value of pH 7.24, taking into account also the average salivary flow rate (0.5ml/min) (1.b).

A tablet from each formula was placed in the equipment for the desorption of the miconazole nitrate and the equipment was started so that 0,5mL AFNOR artificial solution per minute was dropping on the tablet. The tablet is kept in this installation until it totally disintegrates. The artificial saliva solution that has disintegrated the tablet is being collected every 20 minutes. Therefore, every 20 minutes one has collected 10mL from the sample, which was introduced in porcelain capsules, being evaporated on dry, on a water bath.

The residue of the porcelain cap was eluted with 1 mL of solution of methanol with chloroform. Also, in the porcelain capsule one has added 8 mL 1,2 dichloroethane and 1 mL iodine solution 0.01M. From the homogenized sample one has collected 500µL for the spectrophotometric method performed with the device MICROLAB 300 and for the colorimetric method one has collected 1 mL sample.

RESULTS AND DISCUSSION

By determining the disintegration time according to method A from FR X (5) above mentioned, one has been achieved for the first formulation a disintegration time of 25 minutes, for the second one a disintegration time of 45 minute, for the IIIrd formula 60 minutes, formula IV 65 minutes and for the final formulation a 90 minutes time (fig. 2).

The decomposition of mucobioadhesive tablets with miconazole nitrate by means of

the new method leads to the following results: the first formulation disintegrates in 30 minutes, the second in 80 minutes, the third in 340 minutes, the fourth in 360 minutes and the last formula, respectively the fifth formula in 380 minutes (fig. 3).

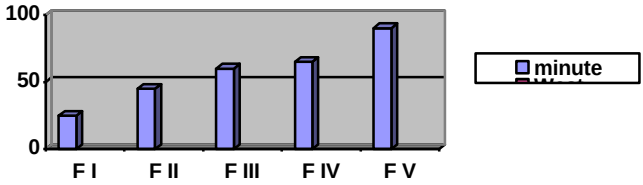

Fig. 2 Decomposition time of oral biomucoadhesive tablets with miconazole nitrate by method A (FR X)

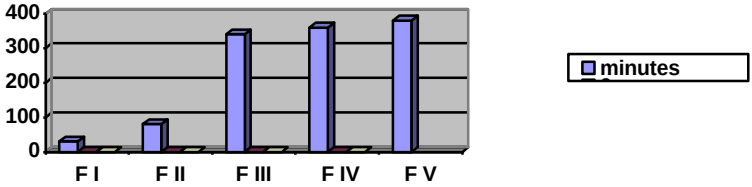

Fig. 3 Decomposition time of oral biomucoadhesive tablets with miconazole nitrate by simulating *in vivo* conditions.

From the above results we can see a prolonged disintegration time when we simulate the conditions at the level of oral mucosa. Thus, the pH, the saliva flow and also the temperature are important factors which influence the disintegration time. Formulae III, IV and V have a much higher disintegration time compared to formulae I and II, a phenomenon explained by: the presence of sodium carboxymethyl cellulose in a higher quantity for the last three formulae(100 mg-F3;100 mg-F4;140 mg-F5) and also the presence of polyethylene glycol in admixture with CMC-Na added in a higher quantity for the last two formulae(100 mg CMC-Na /40 mg PEG /cpr; 140 mg CMC-Na / 20 mg PEG /cpr). Formula III contains CMC-Na but not PEG, the substance added in the highest quantity (140 mg/cpr) in formula V.

The yield profile of the miconazole nitrate in the solutions from disintegration by the classical method from FR X (method A) by HPLC dosage (tab.II, fig. 4) was researched.

It is noted that the release of miconazole nitrate from oral biomuco-adhesive tablets varies in time, depending on the type and ratio of the matrix forming polymers. The antifungal's yield depends on the amount of polymers. The most important factor influencing the rate of release of the miconazole nitrate is the ratio between it and the polymers: CMC-Na and PEG 6000.

An increase in concentration of CMC-Na polymers increases the viscosity of the gel formed with the dissolution agent and also the forming of a gel layer around the

tablet, which reduces the rate of diffusion of the active substance. The release mechanism appears to be a swelling or erosion one of the tablets, which is observed during the yield study and also at the dynamic dissolution test.

TABLE II

***In vitro* yield of the miconazole nitrate from mucobioadhesive tablets (HPLC dosage)**

Time/ Miconazole nitrate %	30’	60’	90’	120’	150’	180’	210’
Formula I	8,32	9,75	10,0	10,52	13,53	14,00	14,61
Formula II	5,80	6,15	8,35	10,30	12,16	12,36	14,48
Formula III	3,88	6,43	7,60	7,80	10,20	10,50	10,70
Formula IV	4,25	6,00	10,00	10,20	10,50	11,50	12,40
Formula V	3,50	6,00	9,70	9,90	10,00	10,40	11,50

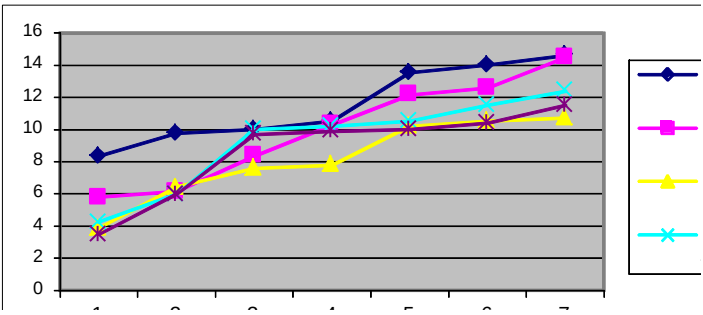

Fig. 4 The yield profiles of miconazole nitrate from I-V formulae after decomposition according to A FRX decomposition

Also, there was a low yield rate of the miconazole nitrate from mucobioadhesive tablets during the research time: the largest yield of 14.51% within 3h and 30'o represents formula I and 14.48% represents formula II followed by formula IV with 12.4%, formula V with 11.5% and formula III with 10.7%.

The yield profile of miconazole nitrate in solutions of disaggregation by the new method, by colorimetric and spectrophotometric dosage was studied. Experimental results are processed in Figure 5. A more effective yield was registered for tablets of formulas I and II, which are noted as having a lower concentration of CMC-Na.

Further one presents the method used in determining the concentration of miconazole nitrate involved in AFNOR saliva solution to pH = 7.24 and D = 0.5 ml/min. The total percent of miconazole nitrate released from the tablet of formula I, in the presence of AFNOR saliva is of 83,49%, in formula II -79 943%, in formula III -45 717%, formula IV - 49.392% and the formula V is of 52.264%.

It is important to keep in mind this fact, so that during drug administration, one maintains the required concentration for the destruction of fungi in a certain time, so that they do not form as in the case of the antibiotic, drug-resistant strains (fig. 5).

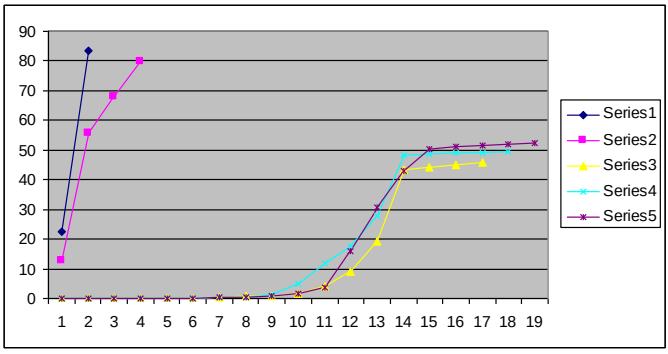

Fig. 5 Yield percents of miconozole nitrate from mucobioadhesive tablets, presented in a graphic

CONCLUSIONS

From the results of this research regarding the tablets' disintegration, it is noted that formula V has the longest disintegration time, that is of 90 minutes, as determined by the method of FRX and of 380 minutes by means of dynamic method, which simulates *in vivo* conditions. Validation study performed on a dosage method adapted for the miconazole nitrate by means of HPLC shows that the method is linear, selective, accurate, precise and robust. The release of *in vitro* miconazole nitrate from oral bio-mucoadhesive tablets varies in time depending on the type, concentration and the ratio of polymers: CMC-Na/PEG.

In the study performed, one has observed both *in vitro* and *ex vivo* yield. These results explain the role of yield conditions (pH, temperature, flow of saliva, etc). Basically, I have noticed a substance release up to 16% in *in vitro* yield and up to 83.49% in *ex vivo* yield. The release of miconazole nitrate from formulated and studied biomucoadhesive tablets, concerning swelling and erosion.

A COMPLEX SYSTEM FOR TELEMONITORING OF MEDICAL VITAL SIGNS (Abstract): A complex goal in biomedical information technology today is the design and implementation of telemedicine and e-health solutions, which provide (chronic) patients and elderly people services that can enhance their quality of life. **Material and Methods:** We used wireless sensor network technology, low-power integrated embedded systems and wireless communications, which have enabled us the design of low-cost, miniature, precise and intelligent physiological sensor modules. These modules are capable of measuring, processing, communicating one or more physiological parameters, and can be integrated into a wireless personal area network (WPAN). **Results:** We have designed, deployed, produced and tested both hardware and software medical sensors for WPAN, dedicated to vital signs acquisition, processing and transmitting, as well as the whole telemedical system for these physiologic parameters monitoring in real time. **Conclusions:** This paper is dedicated to the most complex Romanian telemedical pilot project, TELEMON, that has as goals the design and implementation of a system for automatic and complex telemonitoring, everywhere and every time, in (almost) real time, of the vital signs of persons with chronic illnesses, of elderly people, of those having high medical risk and of those living in isolated regions. The final objective of this pilot project is to enable personalized telemedical services, and to act as a basis for a public service for telemedical procedures in Romania and abroad. **Keywords:** TELEMEDICINE, TELEMONITORING, BIOMEDICAL DEVICES, WIRELESS PERSONAL AREA NETWORK, BIOMEDICAL SIGNAL ANALYSIS.

Ageing of the population has resulted in a sustained increase in family and state healthcare expenses – it is now close to 10% of EU gross domestic product (GDP) and is growing every year. Successful ageing means maintain physical, cognitive, and social activities, live an independent life of one's own choice and maintain an appropriate quality of life (QoL). Senior citizens wish to remain living at home for as long as possible, despite the appearance of motor and/or cognitive impairment. Some of these individuals require moral and/or physical support 24 hours a day, a

situation difficult to deal with without sustained family support or institutionalization. Solutions supporting independent living at home and outdoors are one of the main alternatives to institutionalization, implying a significant reduction in healthcare costs. Telemonitoring is one of the alternatives that provide users and their families with confidence and satisfaction, since it allows elderly patients with chronic diseases or very frail to live independently in their own home with direct contact to the professionals, relatives and friends.

Our project, TELEMON, enables designing of a secure multimedia transmission system (medical records, digital images, video, and text) in order to enhance the telemedical consultancy services. The main objective of this project is to enable personalized teleservices delivery and patient safety enhancement based on an earlier diagnosis with medical telemetry using biosignals, images, text transmissions, and also applying the suitable treatment according to the remote medical experts' recommendations (1, 2). Our project allows persons with different (chronic) diseases and to elderly/lonely people to be monitored from medical and safety points of view. In this way the medical risks and accidents are diminished. The TELEMON system acts as a pilot project destined to the implementation of a public e-health service, "everywhere and every time", in real time, for people being in different hospitals, at home, at work, during the holidays, on the street, etc.

MATERIALS AND METHODS

The main objective of this project is the achievement of an integrated system, mainly composed by the following components in a certain area: a personal network of wireless medical sensors on the ill person (fig. 1), a personal server on the same patient (a smartphone), and a personal computer (PC). After local biosignal processing, according to the specific monitored feature, the salient data are transmitted via one of internet, GSM/GPRS or a telephonic line to the database server of the Regional Telemonitoring Centre. The personal network of sensors includes at least one medical device for vital signs acquisition, or a fall detection module, all these components having radio microtransmitters, which allows an autonomic movement of the subject.

The project also approaches the situation of *the mobile patient*. Data processing is done by a Personal Digital Assistant or a smartphone with GPS localization, and data transmission is done by the GSM module of the PDA.

Concerning the application programs, they act and correlate on two levels: a local data processing, near the patient, as well as another processing on database central server. So, the general software architecture is a client-server one, and the project develops a so-called *SOA – Service Oriented Architecture* – which is a standards-based approach to manage services made available by different software packages for reuse and reconfiguration (3).

The results of data processing are in principal and if necessary different locally generated alarms, transmitted to the central server, to the family or specialist doctor, to the ambulance or to a hospital. Other results of locally or on server data processing are different medical statistics, necessary for the evaluation of health status of the subject, for the therapeutic plan and for the healthcare entities. The TELEMON system is built around a database server that re-

ceives data from local subsystems, also from mobile subsystems, and stores them. Also, the database server can be connected to another database server, for example a hospital server. The subsystems are connected to the database server through Internet (if it is available) or a GSM connection.

The following medical devices were chosen to allow a good monitoring of the vital parameters:

a) A *3-leads ECG module* to record and transmit data through a radio transceiver interface. This sub-system allows detection of various abnormalities of electric heart activity, focusing only on those which can be life threatening and thus a medical emergency, such as: (i) rhythm modifications: severe bradychardia (<45/min) or tachycardia (> 140/min or even asystole – the heart rate equals 0 for at least 3 sec.); (ii) recently installed AV blocks; (iii) signs of myocardial ischemia: new, significant pathological Q wave, elevation of the ST segment > 200 μV or depression of the ST segment < –150 μV, negative T wave; (iv) enlargement of the QRS complex > 0,12 sec; (v) prolonged QT interval > 0,45 sec. We have adapted algorithms for the extraction of the ECG features based on digital filters (4), especially algorithms for the QRS complex and ST segment detection. The module is useful for patients with heart complications or at risk for myocardial/vascular problems, who represent more than 80% of the elderly population.

b) The *arterial pressure module*, with serial interface. This module identifies significant variation of blood pressure such as hypotension or hypertension and is very important for elderly persons, who are prone to this kind of oscillations. Postural hypotension is one of the most frequent situations a senior person must deal with; its complications are severe, impairing the quality of life and becoming life threatening (e.g.: falls, syncope, and stroke).

As practical solution, a commercially available A&D UA-767PC BPM was used. The blood pressure monitor (BPM) takes simultaneous blood pressure and pulse rate measurements. It includes a bi-directional serial port connection communication at 9600 kbps. A eZ430-RF2500 module communicates with the BPM on this serial link to start the reading process and receives the patient's blood pressure and heart rate readings. Once the readings are received, the eZ430-RF2500 communicates with the network and transmits them to the Personal Server (PDA). PDA computes blood pressure and defines the status of the patient by using the following blood pressure values (by default), that can be adjusted and personalized by specialized physicians (cardiologists): Hypotension: systolic < 90 mmHg or diastolic < 60 mmHg; Normal: systolic 90–119 mmHg and diastolic 60–79 mmHg; Pre-hypertension: systolic 120–139 mmHg or 80–89 mmHg; Stage 1 Hypertension: systolic 140–159 mmHg or diastolic 90 – 99 mmHg; Stage 2 Hypertension: systolic ≥ 160 mmHg or diastolic ≥ 100 mmHg.

c) The *oxygen saturation module* (SpO_2). A large number of elderly patients have respiratory insufficiency due to chronic pulmonary diseases. The evolution of their respiratory capacity is strongly influenced by weather, exposure to allergens, humidity and compliance to treatment, therefore detection of oxygen saturation is a very useful thing. A decrease of arterial blood oxygen < 90% triggers the alarm system.

The *pulsoximeter sensor* used is Micro Power Oximeter board from Smiths Medi-

cal (5). The same sensor can be used for heart rate and SpO_2 detection. The probe is placed on a peripheral point of the body such as a fingertip, ear lobe or the nose. The pulsoximeter communicates with the eZ430-RF2500 through asynchronous serial channel at CMOS low level voltages. Data provided includes $\%SpO_2$, pulse rate, signal strength, and plethysmogram.

d) The use of wireless *breathing module* is suitable for continuous long-time monitoring of human respiration for a number of medical conditions requiring analysis of respiratory rhythm, sleep-related breathing disorder and ischemic heart disease or can be useful during recovery from an acute event or surgical procedure. Our module uses one of the most usual methods to sense breathing, i.e. using a nasal thermistor (6). The sensor is designed using MSP430F2274 microcontroller with an on-chip 10 bit A/D converter for data acquisition (10 Hz sampling frequency) and CC2500 2.4 GHz wireless transceiver. The thermistor detects changes of breath temperature between ambient temperature (inhalation) and lung temperature (exhalation). The used thermistor is a 0603 SMD type and has as main characteristics: R_{nom} = 10 kΩ at 25°C, B = 3380, 1% tolerance. The Personal server on patient computes the following parameters: Breathing amplitude - calculated for every breathing cycle as a difference between minimum (Inhalation) and maximum thermistor voltage (Exhalation); Breathing interval – measured between two signal minima; Breathing frequency, calculated as a number of breaths per minute. Normal breathing frequency is 12-20 cycles/minute. We consider two types of respiration: normal respiration, when every breath lasts more than 0.5 seconds; apnea, when the breathing is missing for more than 10 seconds.

e) The *body temperature module* gives important information about occurrence of fever, especially for persons with mild cognitive impairment who cannot sense temperature modifications (> 38 °C or < 35 °C). We used the TMP275 temperature sensor (Texas Instruments). The TMP275 is directly connected to the eZ430-RF2500 module. The accuracy for the 35-45°C interval is below 0.2 °C. The Personal server samples the signal from the temperature sensor once per second and computes the status of the patient for the following temperature values: low temperature – <35°C; high temperature – >38°C; normal temperature – between the above values.

f) The *fall detection module* should be recommended to all senior persons who live alone. Elderly people are exposed to falls due to several causes: (i) postural hypotension (induced by inadequate hydration, cervical spondilosys with vertebrobasilar circulatory problems or even inappropriate medication for hypertension); (ii) inappropriate house conditions such as poor lighting conditions, narrow halls or staircases, slippery surfaces which predispose losing balance and fall; (iii) sensory disturbances (visual, postural) that induce imbalance and fall; (iv) inappropriate shoeing and/or clothing. Early detection of an elderly who had a fall is of extreme importance for recovering personal health and mental state after such a traumatizing event. Our fall detection module is based on accelerometer technique, that can recognize four kinds of static postures: standing, bending, sitting, and laying. Motions between these static postures are considered as dynamic transitions. If the transition before a lying posture is not intentional, a fall event is detected.

Our method uses the ADXL330 3-axes accelerometer and eZ430-RF2500 Wireless Modules. The ADXL330 is a small, thin, low power, complete, three axial accelerometer with signal conditioned voltage outputs, all on a single monolithic IC. We determine if the subject has fallen if the condition $a_A = \sqrt{a_{A_x}^2 + a_{A_y}^2 + a_{A_z}^2} > 0.4g$ is valid.

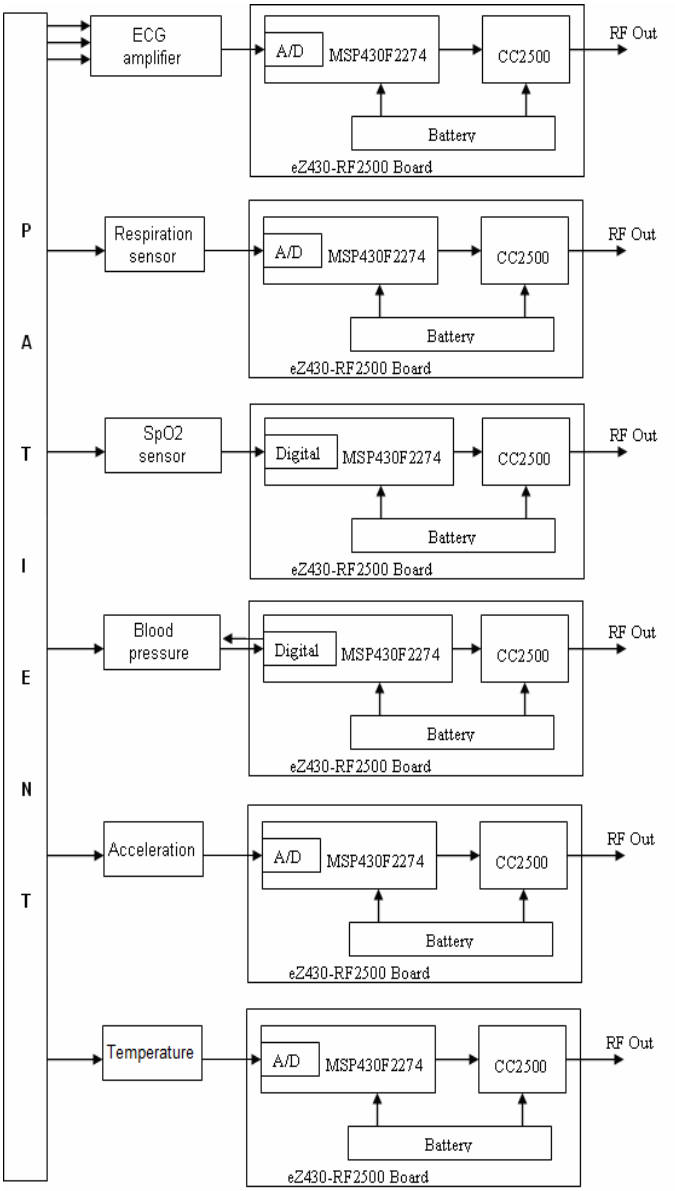

Fig. 1. The local subsystem for home monitoring of the patient

The modules (a, d, e, f) were made by our research team, while modules (b) and (c) were chosen from the market and were integrated in TELEMON system (www.bioinginerie.ro/telemon) (Fig. 1). These modules transmit data to a PDA through radio transceivers (eZ430RF2500 boards), can operate in the 2.4 GHz band, and have 5m /10m range indoors /outdoors. The eZ430-RF2500 is a complete MSP430 wireless development tool (7) providing all the hardware and software for the MSP430F2274 microcontroller and CC2500 2.4 GHz wireless transceiver (8). Operating on the 2.4 GHz unlicensed industrial, scientific and medical (ISM) bands, the CC2500 provides extensive hardware support for packet handling, data buffering, burst transmissions, authentication, clear channel assessment and link quality. The radio transceiver is also interfaced to the MSP430 microcontroller using the serial peripheral interface. The USB interface enables eZ430-RF2500 to remotely send and receive data through USB connection using the MSP430 Application UART.

RESULTS

The personal server was implemented by means of a PDA (Toshiba TG01C) (Fig. 2). This personal medical monitor is responsible for a number of tasks, providing a transparent interface to the wireless medical sensors, an interface to the patient, and an interface to the central server. Its USB interface is realized by using a serial-to-USB transceiver (FT232BL) from FTDI (9) and enables eZ430-RF2500 radio module to remotely send and receive data through USB connection using the MSP430 Application UART. All data bytes transmitted are handled by the FT232BL chip.

The software on the Personal Server receives real-time patient data from the sensors and processes them to detect anomalies. The software working on the Personal Server (Fig. 3) was written by using C# from Visual Studio.NET, version 8. The software displays temporal waveforms, computes and displays the vital parameters and the status of each sensor (the battery voltage and distance from the Personal Server). The distance is represented in percent, based on RSSI (received signal strength indication, measured on the radio power present in a received radio signal).

If the patient has a medical record that has been previously entered, information from the medical record (limits above the alarm become active) is used in the alert detection algorithm. So, when an anomaly is detected in the measured patient vital signs, the Personal server application generates an alert in the user interface and transmits the information to the TELEMON Server. For instance, the following physiological conditions cause important alerts:

low SpO2, if SpO2 < 90%; bradycardia, if HR < 40 bpm (HR = heart rate); tachycardia, if HR > 150 bpm; HR change, if ΔHR / 5 min > 20%; HR stability, if max HR variability from past 4 readings > 10% ; BP change, if systolic or diastolic change is > ±10% .

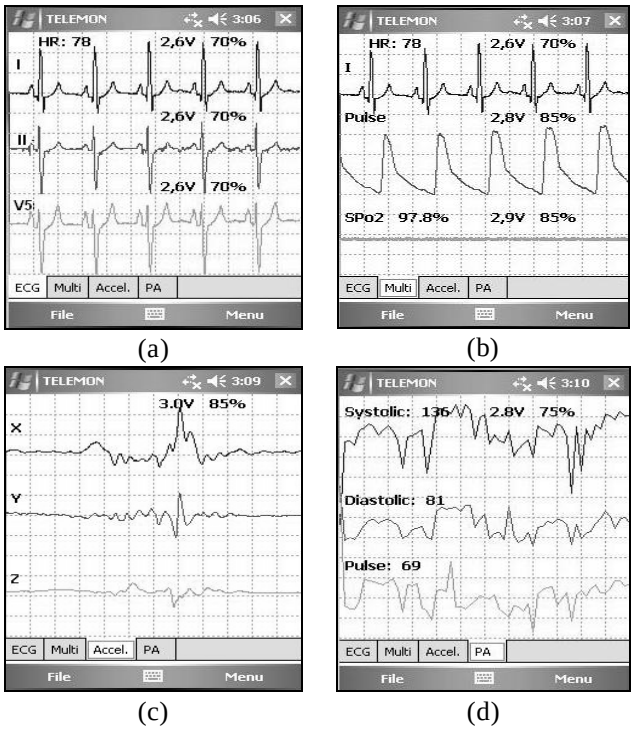

Fig. 3. The Personal server interface: (a) 3 ECG traces, (b) one ECG trace, pulse waveform and SpO2, (c) 3 accelerometer traces, (d) systolic and diastolic pressure from the blood pressure monitor

DISCUSSION

In this paper it is presented a project that acts as base for developing a secure multimedia, scalable system, designed for medical consultation and telemonitoring services. The main goal is to build a complete pilot system that will connect several local telecenters into a regional telemedicine network. This network enables the implementation of teleconsultation, telemonitoring, homecare, urgency medicine, etc. for a broader range of patients and medical professionals, including elderly people and those people living in rural or isolated regions (10–14).

The Regional Telecenter in Iasi / Romania, situated in the Faculty of Medical Bioengineering, allows local connection of hospitals, diagnostic and treatment centers, as well as a local network of family doctors, patients, paramedics and even educational entities. As communications infrastructure, we have developed a combined fix-mobile-internet (broadband) links. The proposed system is also used as a warning tool for monitoring during normal activity or physical exercise. Such a regional telecenter acts as a support for the developing of a regional medical database, that should serve for a complex range of teleservices such as teleradiology, telepathology, teleconsulting, telediagnosis, and telemonitoring. It should also be a center for continuous training and e-learning tasks, both for

medical personal and for patients.

Also, the telemonitoring of elderly people who want to preserve as long as possible their independence but are of medical risk (cardiovascular, respiratory, proneness to falls) represents one of the most important solutions to an aging Europe. Besides the medical and technical objectives, TELEMON project also proposes important economic objectives: (i) the decrease of budgetary and personal expenses dealing with the unjustified transport of patients to the hospital; (ii) „zero costs" for the hospitalization in the case of patients who may be treated at home.

Discipline of Microbiology

NEW HYDRAZONES WITH PYRAZOLONE STRUCTURE: SYNTHESIS, CHARACTERIZATION AND BIOLOGICAL EVALUATION(Abstract): **Aim:** To design new hydrazones with pyrazolone structure with improved biological properties. **Material and methods**: New hydrazones of antipyrine have been prepared by reaction of 4-aminophenazone (4-aminoantipyrine) with chloracetylchoride and hydrazine hydrate and then condensation with various aromatic aldehydes. **Results:** The synthesized compounds were screened for their antibacterial activity against Gram positive (*Staphylococcus aureus* ATCC 25923, *Sarcinalutea* ATCC 9341, *Bacillus cereus* ATCC 14579, *Bacillus subtilis*) and Gram negative bacterial strains (*Escherichia coli* ATCC 25922) and pathogenic yeasts (*Candida albicans* ATCC 10231, *Candida sake*, *Candidaglabrata*). Some of them were found to have good antibacterial and antifungal activity. The antioxidant activity of these compounds was also evaluated using the total antioxidant capacity test. **Conclusions:** The chemical modulations performed on antipyrine structure have a good influence on the biological activity of the synthesized compounds. **Keywords:** ANTIPYRINE, HYDRAZONES, ANTIBACTERIAL, ANTIFUNGAL, ANTIOXIDANT.

Non-steroidal antiinflammatory drugs (NSAIDs) represent a heterogeneous family of pharmacologically active compounds used in the management of acute and chronic inflammation, pain and fever. Their mechanism of action is related to their ability to inhibit both COX-1 and COX-2 isoforms of the cyclooxygenase enzyme (COX) (1). COX-1 is a constitutive isoform and it is responsible for synthesis of prostaglandins with cytoprotective effects in gastrointestinal tract and control of renal function. The inductible COX-2 isoform is selectively activated by pro-inflammatory stimuli and facilitates the release of prostaglandins involved in the inflammatory process (2). Because most of NSAIDs are nonselective COX inhibitors their long-term clinical use is associated with significant side effects, such as gastrointestinal damage, bleeding and nephrotoxicity. The pyrazolone derivatives are important drugs among NSAIDs. Starting with 1884, when antipyrine was marked as drug used in management of pain,

inflammation and fever, great attention was focused on pyrazolone derivatives as potent anti-inflammatory, analgesic and antipyretic agents. As a result, a large number of pyrazolone derivatives have been developed and some of them marked as important drugs (3). For example, Celecoxib is a selective COX-2 inhibitor with anti-inflammatory, analgesic properties and few gastrointestinal side effects. Up to now, broad properties of antipyrine derivatives have been investigated as antitumor, antimicrobial, antiviral, analgesic and anti-inflammatory agents (4-8).

This study presents the synthesis, physico-chemical and spectral characterization and also evaluation of the antioxidant and antimicrobial activity of new antipyrine derivatives.

MATERIAL AND METHODS

4-amino-antipyrine, chloroacetyl chloride, organic solvents (*p.a.* quality), standard reagents for antioxidant and antimicrobial tests were purchased from Sigma Aldrich Company. All solvents and reagents were used without further purification.

Chemistry.*Synthesis of antipyrine derivatives.*4-aminoantipyrine (1,5-dimethyl-2-phenyl-4-amino-1,2-dihydro-3H-pyrazol-3-one) (1) was reacted with chloroacetyl chloride in dry acetone and in the presence of anhydrous potassium carbonate (fig. 1). The resulting N-chloroacetyl-aminoantipyrine (2) was then reacted with hydrazine hydrate in anhydrous ethanol and the hydrazine derivative (3) was then reacted with various aromatic aldehydes when new hydrazone derivatives (4-9) were obtained.

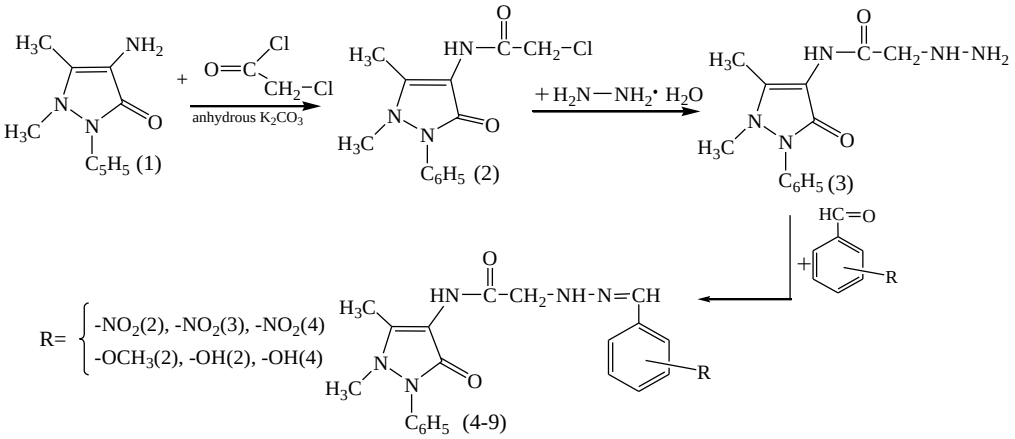

Fig. 1. Synthesis of new hydrazones (4-9) with pyrazolone structure.

Synthesis of 2-chloro-N-(1,5-dimethyl-3-oxo-2-phenyl-1,2-dihydro-3H-pyrazolyl) aceta-mide(1). 4-aminophenazone (10 mmol, 2.03 g) was dissolved in 20 ml chloroform and then chloracetic chloride (10 mmol, 0.8 ml) and anhydrous potassium carbonate (10 mmol) were added. The reaction mixturewas heated under reflux for 8 h and then filtered off and evaporated. The reaction progress was monitored by Thin Layer Chromatography (TLC) (ethyl acetate: acethone: hexane 5:2:1; Rf 0.62). The crude product was treated with crushed ice and the solid was filtered off, washed with sodium bicarbonate (10 ml) and water (10 ml) and then recrystallized from ethanol.

White-yellow powder, yield 87%, m.p. 189-190°C. IR (cm^{-1}): 1690 (CO-NH), 654 (C-Cl).

Synthesis of N-(1,5-dimethyl-3-oxo-2-phenyl-1,2-dihydro-3H-pyrazolyl)-2-hydrazinyl-acetamide (2).Hydrazine hydrate (5 mmol) and magnesium sulphate (0.5 g) were added in 25 ml absolute ethanol at 0°C and then chloracetyl derivative of aminoantipyrine (1 mmol, 0.279 g) (2) in 10 ml ethanol was added drop wise for 15 min. The reaction mixture was stirred at room temperature for 8 h, left overnight and then filtered off in order to remove the excess of magnesium sulphate. The solution was evaporated and the product was washed three times with chloroform. The progress of reaction was monitored by TLC (dichlormethane : methanol 1:1; Rf 0.25). White powder, yield 58 %. IR (cm^{-1}): 1654 (CO-NH), 3433, 3327 (NH_2).

General procedure for synthesis of 2-(2-benzylidenhydrazinyl)-N-(phenazon-4-yl) acetamide(4-9).To a solution of hydrazine derivative of aminoantipyrine (1 mmol, 0.28 g) (2) in ethanol (10 ml), aromatic aldehydes (1 mmol) and glacial acetic acid (2-3 drops; pH 4-5) were added. The reaction mixture was heated under reflux for 5 h. The obtained solidwas filtered off and recrystallized from ethanol.

Characterization by FTIR Spectroscopy. Fourier transform infrared (FTIR) spectra were recorded on a FT-IR Bomem MB-104 spectrometer (Canada). FTIR spectra were acquired after 32 scans between 4000 and 600 cm^{-1}, with spectral resolution of 4 cm^{-1}. Spectra processing was carried out with a Grams/32 program (Galactic Industry Corporation).

Antioxidant assays. *Determination of total antioxidant capacity*.

The antioxidant activity of tested compounds was evaluated using phosphomolybdenum method according to the procedure of (9) with minor modifications. Briefly, 300 µL sample solution of various concentrations (500 µg/ml, 250 µg/ml, 125 µg/ml, 62.5 µg/ml) in DMSO was mixed with the reagent solution (2 ml 0.6 M sulphuric acid, 28 mM sodium phosphate and 4 mM ammonium molybdate). The samples were incubated at 95°C for 90 minutes. After the mixture was cooled to room temperature, the absorbance of each solution was measured at 695 nm against a blank (DMSO mixed with the reagent solution). Ascorbic acid (AA) was used as standard antioxidant in the same concentration of the samples.

Antimicrobial assessment. The antimicrobial activity was studied using Gram positive (*Staphylococcus aureus* ATCC 25923, *Sarcinalutea* ATCC 9341, *Bacillus cereus* ATCC 14579, *Bacillus subtilis*,), and Gram negative bacterial strains (*Escherichia coli* ATCC 25922) and pathogenic yeasts (*Candida albicans* ATCC 10231, *Candida sake*, *Candidaglabrata*). Antimicrobial activity was initially evaluated by agar disc diffusion method according to described protocols (CLSI, 2012). Sterile stainless steel cylinders (50 mm internal diameter; 100 mm height) were applied on the agar surface in Petri plates. 200 µL of the tested compounds (4-9) (10 mg/ml) were added to each cylinder. Commercially available discs containing ampicillin (25 mg/disc), chloramphenicol (30 mg/disc) and nystatin (100 mg/disc) were used. The plates were incubated at 37°C for 24 h (bacteria) and at 24°C for 48 h (yeasts). After incubation the diameters of inhibition zones were measured.

RESULTS AND DISCUSSION

Chemistry. The physical measurements

of the compounds are presented in tab. I and the characteristic IR spectroscopic bands are given in tab. II. In the IR spectra of the hydrazone derivatives of aminoantipyrine (compounds 4-9) the absorption bands characteristic for all functional groups were observed. The absorption band for the C=O group was observed in the range of 1603-1653 cm^{-1}, for the C=N group in the range of 1578-1597 cm^{-1} and for C-N group the characteristic band appears in the range of 1107-1140 cm^{-1}. The bands of benzilydene ring substituents appeared in the range of 1516 -1522 cm^{-1} (asymmetric vibration of NO_2 group), 1342-1356 cm^{-1} (symmetric vibration of NO_2 group), 3070 cm^{-1} (OCH_3), 1200-1230 cm^{-1} (OH). The presence of these bands confirmed the chemical structure of the synthesized compounds.

Antioxidant assays*. Determination of total antioxidant capacity*. The assay for total antioxidant capacity was based on the reduction of Mo^{+6} to Mo^{+5} by the tested compounds followed by formation of a green phosphate/ Mo^{+5} complex at acidic pH. The results of the synthesized compounds are presented in tab. III. At concentrations of 500 μg/ml, 250 μg/ml, 125 μg/ml and 62.5 μg/ml all tested compounds were more active than ascorbic acid (AA) at the same concentrations. The most active compounds were derivatives (7, 9), which were obtained through condensation of hydrazine derivative of antipyrine with 2-methoxybenzaldehide and 4-hydroxybenzaldehyde, respectively.

TABLE III

Absorbance of the tested compounds at various concentrations compared with ascorbic acid (AA)

*Antimicrobial assessment.*The inhibition zone diameters (mm) of the tested compounds on bacterial strains and yeasts are presented in figs. 2 and 3. According to the results, the most active compounds were (5), (R = -NO_2(3)) and (8) (R = -OH(2)). Compound 5 was active both on bacterial strains and yeasts, while compound 8 was active especially on bacterial strains. The antimicrobial activity of these compounds was comparable with that of ampicillin and chloramphenicol (bacterial strains) and nystatin (yeasts).

The inhibition zone diameters for compound 5 on yeasts were 22 mm(*Candida albicans* ATCC 10231), 25 mm (*Candida sake*) and 20 mm (*Candidaglabrata*). As to the antibacterial activity of compound 5, it was noticed that it was active especially on *Pseudomonas aeruginosa* and *Sarcinalutea* strains. Compound 8 also had an important antibacterial activity on Gram positive and Gram negative bacteria.

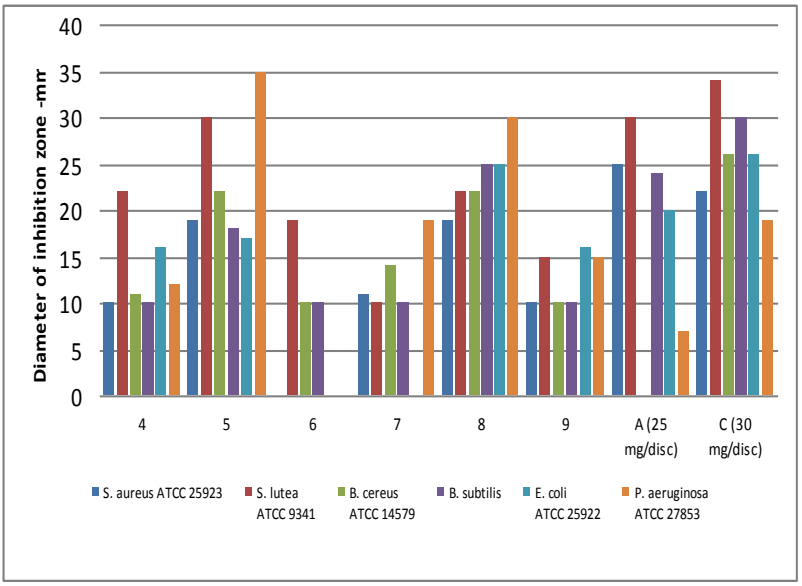

Fig. 2. Antibacterial activity of compounds(4-9)(A-Ampicillin, C-Chloramphenicol)

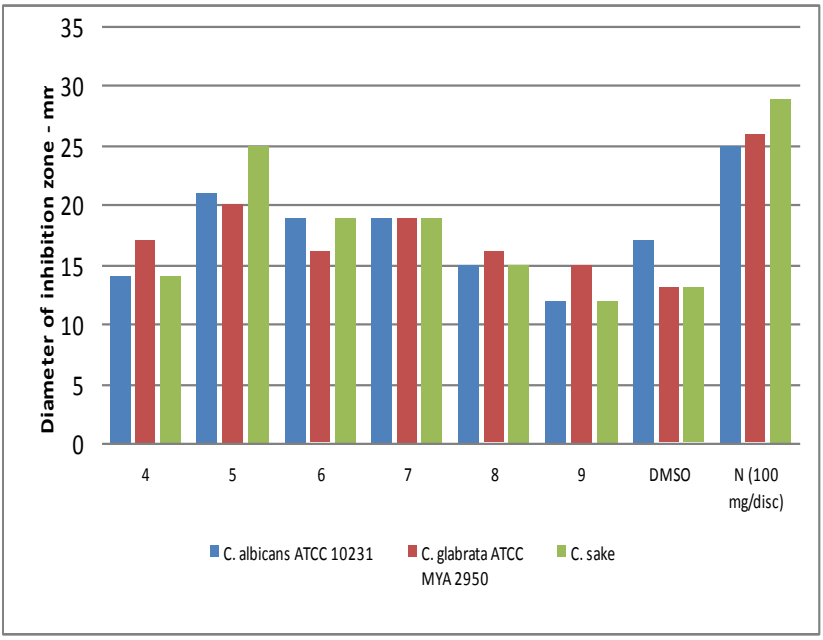

Fig. 3. Antifungal activity of compounds (4-9) (N-Nystatin)

CONCLUSIONS

Some new hydrazones with pyrazolone structure have been synthesized and optimal conditions of reaction were established for obtaining compounds with high yields and advanced purity. The synthesized compounds have been characterized by their physical constants (melting point, yield, molecular formula, molecular weight, solubility in different organic solvents) and their chemical structure was confirmed by FT-IR spectroscopy. Their antibacterial and antioxidant activities have been also evaluated. Some compounds possessed important antimicrobial and antioxidant activity.

NEWS

HERBAL MEDICINES WITH ANTI-PARKINSONIAN ACTIVITIES

Parkinson's disease is a chronic neurological disorder. In recent years, increasing interest has been devoted to the treatment or prevention of Parkinson's disease by herbal medicines. Li et al. summarized and analyzed the anti-Parkinsonian activities of several herbal medicines and herbal formulations. All the herbal medicines and herbal formulations were tested on Parkinson's disease models both *in vitro* and *in vivo*. A total of 38 herbal medicines and 11 herbal formulations were analyzed. The relevant compounds, herbal extracts and formulations were reported to be effective on Parkinson's disease models by modulating multiple key events or signaling pathways implicated in the pathogenesis of the disease. The plant species of these herbal medicines belonged to 24 genera (*Acanthopanax*, *Alpinia*, *Astragalus*, *Camellia*, *Cassia*, *Chrysanthemum*) and 18 families. These herbal medicines can be an alternative and valuable source for anti-Parkinsonian drug discovery. According to this study, the plant species in these genera and families may be the most promising candidates for further investigation and deserve further consideration in clinical trials (Li XZ, Zhang SN, Liu SM et al. Recent advances in herbal medicines treating Parkinson's disease. *Fitoterapia* 2013; 84: 273-285).

NEW HYDRAZINES WITH SULPHONAMIDIC STRUCTURE: SYNTHESIS, CHARACTERIZATION AND BIOLOGICAL ACTIVITY (Abstract): Infections caused by bacterial species are common in immunocompromised patients and carry significant treatment costs and mortality. The emerging resistance of microorganisms to some synthetic antimicrobial agents makes it necessary to continue the research for new antimicrobial drugs. **Aim:** To design new sulphonamide compounds with potential antibacterial and antioxidant activity. **Material and methods**: New N-hydrazino acetyl-sulphonamides were prepared by condensation of some sulphonamides with chloroacetyl chloride and amination of intermediate compounds with hydrazine hydrate. **Results:** The synthesized compounds were screened for their antibacterial activity against Gram positive (*Klebsiellapneumoniae*, *Proteus vulgaris*, *Citrobacter freundii*, *Enterobacter cloacae*, *Staphylococcus aureus*, *Staphylococcus epidermidis*, *Enterococcus faecalis*) and Gram negative bacterial strains (*Pseudomonas aeruginosa*, *Escherichia coli*). Some of them were found to have good antibacterial activity. The antioxidant activity of these compounds was also tested using different methods: total antioxidant capacity, reducing power, and DPPH radical scavenging activity. **Conclusions:** Chemical modulations performed on sulphonamide structure have a good influence on the biological activity of the synthesized compounds, especially on their antioxidant effects. **Keywords:** SULPHONAMIDES, HYDRAZINES, ANTIBACTERIAL ACTIVITY, ANTIOXIDANT ACTIVITY.

Sulphonamides and their different derivatives are extensively used in therapy due to their antibacterial activity. They interfere with the use of *p*-aminobenzoic acid (PABA) in the biosynthesis of tetrahydrofolic acid, which is an essential growth factor, vital to the bacterial metabolism (1). The chemistry of sulphonamides has been recently recognized in the preparation of various valuable biologically active compounds used especially as antibacterial agents (2). On the other hand the production of free radicals is relatively increased during infections. Starting from these observations and continuing our research on bioactive molecules, we synthesized some novel hydrazine acetyl-sulphonamides in view of studying their biological activities.

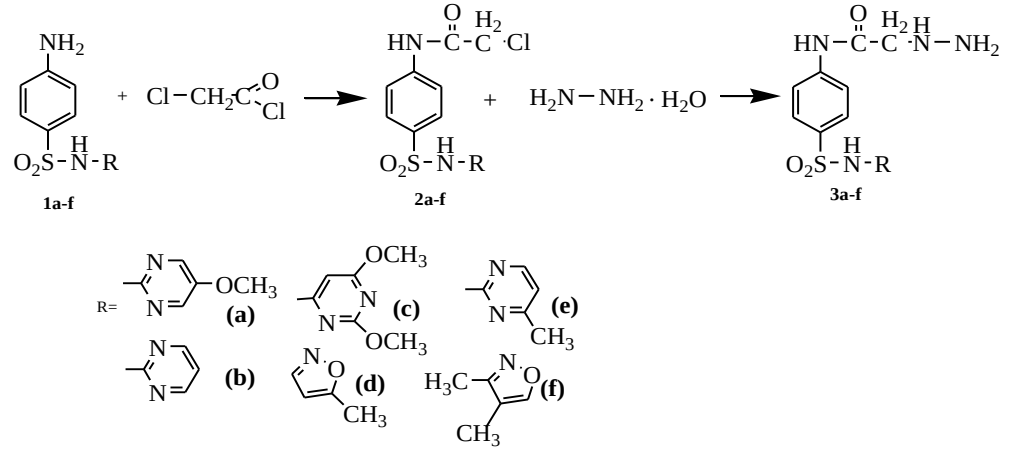
Given their antibacterial and antioxidant potential, these compounds could be used in protecting biological systems from oxidative damage and bacterial infections.

MATERIAL AND METHODS

Sulphonamides, chloroacetyl chloride, organic solvents (*p. a*quality), standard reagents for antioxidant and antimicrobial tests were purchased from Sigma Aldrich Company. All solvents and reagents were used without further purification.

Synthesis of sulphonamide derivatives. Six sulphonamides (sulfamethoxydiazine, sulfadiazine, sulfamerazine, sulfadimethoxine, sulfisoxazole and sulfamethoxazole) were subjected to reaction with chloroacetyl chloride in dry acetone in the presence of anhydrous K_2CO_3 (Scheme 1).

The resulting N-chloroacetyl-sulphonamides have then reacted with hydrazine hydrate in anhydrous ethanol. The reactions were carried out by adapting similar methods used for derivatization of some compounds with primary aromatic amine groups (3, 4, 5, 6).



Scheme 1. Synthesis of new hydrazine with sulphonamide structure

***General procedure for synthesis of N-hydrazinoacetyl-sulphonamides* (3a-f):**

A mixture of each of the compounds **2a-f** (0.04 mole) and hydrazine hydrate (99%, 0.12 mole) in ethanol (150 ml) was refluxed for 10 hours. From the resulting mixture excess ethanol was removed under reduced pressure. The resulting solid residue was purified by recrystallization using the proper solvent and separated by filtration.

Characterization by FTIR Spectroscopy. Fourier transform infrared (FTIR) spectrum was recorded on a Bomem MB-104 FT-IR spectrometer (Canada). All spectra were obtained in the 4000 - 600 cm^{-1}range at a resolution of 4 cm^{-1} over 32 scans. Spectroscopy data were processed with a Grams/32 software (Galactic Industry Corporation).

Antioxidant assays

Determination of total antioxidant capacity. The antioxidant activity of tested compounds was evaluated by the phosphomolybdenum method according to the standard procedure (7) with minor modifications. Briefly 50 µl sample solution (5 mg/ml) in DMSO was mixed with the rea-

gent solution (2 ml, 0.6 M sulphuric acid, 28 mM sodium phosphate and 4 mM ammonium molybdate). The samples were incubated at 95°C for 90 minutes. After the mixture had cooled to room temperature, the absorbance of each solution was measured at 695 nm against a blank (DMSO mixed with reagent solution). Ascorbic acid (AA) in concentration matching that of the samples was used as standard antioxidant.

*Reducing power.*The reducing power of the compounds was quantified by the method described in the literature (8) with minor modifications. Briefly, 1 ml of reaction mixture, containing 5 mg of samples in DMSO, was mixed with 0.2 M sodium phosphate buffer (1 ml, pH=6.6). The reaction was initiated by addition of potassium ferricyanide (1% w/v, 1 ml). After 20 min of incubation at 50°C, the reaction was terminated by trichloroacetic acid solution (10% w/v, 1 ml). The mixture solution was centrifuged at 4500 rpm for 15 min. 1 ml of supernatant was diluted with 1 ml of deionised water, and 0.2 ml ferric chloride (0.1% w/v) solution was added. After 5 min of incubation, absorbance was measured at 700 nm against a blank (the mixture of DMSO with the reagents). Higher absorbance indicates higher reducing power. Effective concentration (EC50: the concentration of a sample in which the absorbance is 0.5 and 50% of substrate is reduced) was calculated.

DPPH radical scavenging activity. The radical scavenging activity of tested compounds against 1,1-diphenyl-2-picrylhydrazyl (DPPH) was measured as described by (9) with a few modifications. 50 µl of each sample solution (20 mg/ml in DMSO) was added to 2950 µl of 0.1 nM DPPH methanol solutions. The mixtures were left at room temperature and in the dark for 30 min, and then absorbance was measured at 517 nm. Ascorbic acid (AA) in concentration matching that of the samples was used as standard.

DPPH methanol solution was used as control sample. The radical scavenging activity was calculated using the following formula: % inhibition = [(control absorbance-sample absorbance) /control absorbance] x 100.

Antimicrobial assessment

The determination of minimum inhibitory concentrations (MICs) of samples was performed by agar dilution method. Nine reference bacterial strains (*K. pneumoniae* CIP 53153, *P. vulgaris* CIP 104989, *C. freundii* CIP 5732, *E. cloacae* CIP 103475, *S. aureus* ATCC 6583, *S. epidermidis* ATCC 12228, *E. coli* ATCC 25922, *E. faecalis* ATCC 25912, *P. aeruginosa* CIP 82118) were included in this study which was performed according to EUCAST standard. The stock solutions were prepared by dissolving 200 mg of each compound in 19.5 ml of DMSO. All stock solutions were stored at 4 °C and used within 24 h. Then 20 ml (19 ml of molten agar to 1 ml of sample solution) were used in 9 cm Petri dishes for agar dilution MICs. The MIC value was defined as the lowest concentration exhibiting no visible bacterial growth at 15°C for 44 to 48 hours and/or 68 to 72 hours.

RESULTS AND DISCUSSION

Chemistry

The hydrazines with sulfonamide structure are crystalline light yellow to light brown powders very soluble in DMF and DMSO. The characteristic IR spectral bands of sulphonamid-hydrazines are shown in table 1. The presence of these bands confirms the chemical structure of

the compounds.

Antioxidant asays

Determination of Total Antioxidant Capacity. The total antioxidant capacity assay is based on the reduction of Mo^{+6} to Mo^{+5} by the tested compounds followed by formation of a green phosphate/ Mo^{+5} complex at acidic pH. The results of the synthesized compounds in comparison with their parent sulphonamides are presented in fig. 1, 2. It was noticed that the most active compound as compared to the parent sulphonamide was 3d while as compared to ascorbic acid 3e.

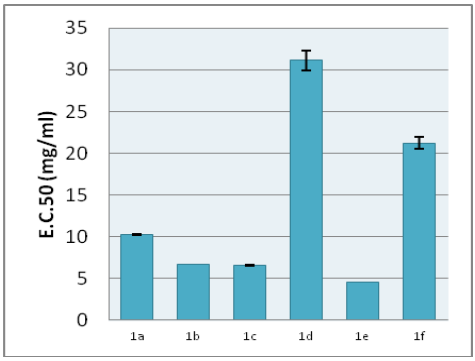


Fig. 1. Total antioxidant capacity of (1a-f)

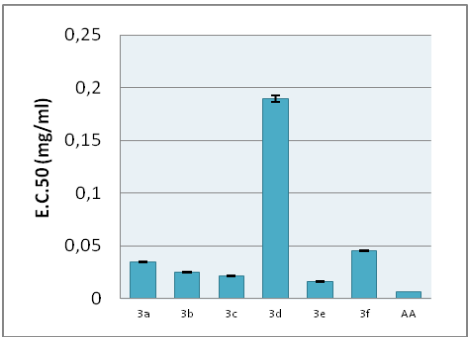

Fig. 2. Total antioxidant capacity of (3a-f)

Reducing power. The synthesized compounds (3a-f) caused the reduction of the Fe^{3+}/ ferricyanide complex to the ferrous form (Fe^{2+}), the colour of the test solution changing from yellow to green depending on the reducing power of each sample. The derivatization of parent sulphonamides with acetyl-hydrazine chain led to increased antioxidant capacity, all tested compounds being more active than parent sulphonamides (fig. 3, 4).

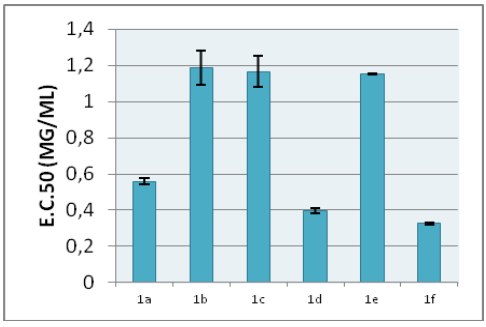

Fig. 3. Reducing power of (1a-f)

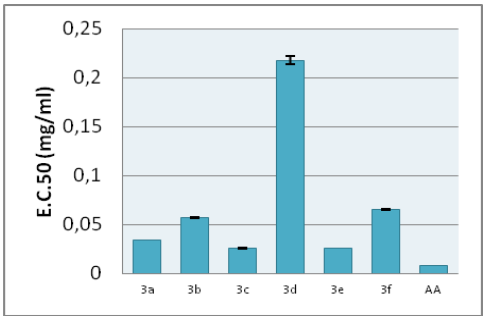

Fig. 4.Reducing power of (3a-f)

*DPPH Radical Scavenging Activity.*The results are presented in figs. 5 and 6. In all six sulphonamides the percentage of inhibition of free radical DPPH is very low (I%=0-36.53), while all six hydrazines have an inhibition percentage (I%=51.25%-97.45%) comparable with that of ascorbic acid (I%=97.59).

*Antimicrobial assessment.*CMI values of the tested compounds are presented in fig. 7, 8. According to the obtained results only N^4 hydrazin acetylamino-sulpha dime-thoxine has a better antimicrobial activity as compared to its parent sulphadimethoxine.

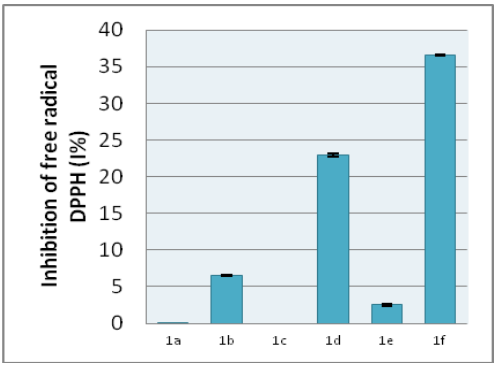

Fig. 5. Radical scavenging activity of (1a-f)

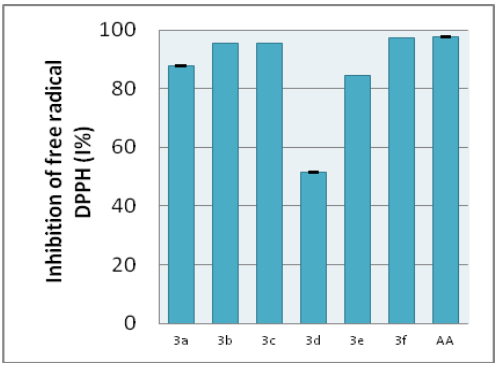

Fig. 6. Radical scavenging activity of (3a-f)

CONCLUSIONS

Some new hydrazines with sulphonamide structure have been synthesized and optimal conditions of reaction were established for obtaining compounds with high yields and advanced purity. The synthesized compounds have been characterized by their physical constants (melting point, yield, molecular formula, molecular weight, solubility in different organic solvents) and their chemical structure was confirmed by FT-IR spectroscopy. Their antibacterial and antioxidant activities have been evaluated. All compounds have marked antioxidant activity compared to the parent sulphonamides and, for some of them; the antioxidant activity is comparable to that of ascorbic acid at the same concentration.

CLINICAL AND BIOLOGICAL FEATURES OF ADULT TOXOCARIASIS (Abstract): **Aim:** To determine the main clinical signs and symptoms of adult toxocariasis and the relationship between anti-*Toxocara canis* antibody levels, symptoms, and the other biological parameters. **Material and methods**: Prospective study conducted in the interval 2008 – 2011 in a series of 457 adult patients from Moldova, Romania. The ELISA method was used to detect the presence of IgG antibodies against *T. canis*. Fasting blood samples were collected from all patients who then underwent the following tests by standard methods: hemoglobin, hematocrit, eosinophils, lymphocytes, white blood cell count, SGOT, SGPT. **Results**: An IgG titer of 1/100 was most commonly found in case of allergies, physical asthenia, sensation of constriction in the anterior cervical area, right hypochondriac pain, paresthesies, nervousness (anxiety) and lipotimic states; a 1/50 titer was most often associated with hive reactions, dysphonia, lower limb edema, and pale/yellow axy skin. In patients with laterocervical adenopathy the most frequent determinations were 1/100 (34.0%), followed by 1/50 (22.6%). **Conclusions**: The statistically significant clinical signs and symptoms may represent a starting point in making a diagnosis of toxocariasis. Of the non-specific laboratory findings we mention: hyperleukocytosis , hypereosinophilia and low hematocit, elevated transaminases level having a high sensitivity and specificity. The diagnosis of certainty is made by determining IgG for *T. canis* or the presence of larvae in the biopsy tissues. **Keywords**: *T.CANIS*, TOXOCARIASIS, CLINICAL DIAGNOSIS, BIOLOGICAL MARKERS

Human toxocariasis is a cosmopolitan helminthic zoonosis due to human parasitization by larvae belonging to species of the Toxocara genus. The most common source of human visceral larva migrans is *Toxocara canis*. "Larva migrans" syndrome was first described by Beaver and colleagues (1952) (1).

In 1954 Beaver mentions the dog as the main source of infection for parasitic diseases. Toxocariasis is a zooanthroponosis with different clinical manifestations depending on the location of larva migrans , degree of activity and number of larvae. The parasitic disease caused by S2 larva is characterized by delayed growth, general, digestive, nervous, ocular and respiratory disturbances and many other pathologic actions (2,8,10,11, 15). Hypereosinophilia, hyperleukocytosis, sometimes ESR and gammaglobulin elevation are biological changes commonly found in toxocariasis, most studies being conducted in children (1.9). For the serological diagnosis of *Toxocara canis* infection the

ELISA method is used.

The aim of this study was to determine the main clinical signs and symptoms of adult toxocariasis and the relationship between anti-*Toxocara canis* antibody levels, symptoms, and the other biological parameters.

MATERIAL AND METHODS

This prospective study was conducted in the interval 2008 - 2011 on a series of 457 adult patients. Patient selection and analysis of medical records were in agreement with the health legislation in force. The study database, retrospective analytical study, was created by using history and physical examination data and interpretation of laboratory tests results.

Positive *T.canis* contact was assessed by determining IgG antibody titer by ELISA method. In all patients the following laboratory test were done by standard methods in fasting blood samples: hemoglobin, hematocrit, eosinophils, lymphocytes, white blood cell count, SGOT, SGPT.

Data from patients' medical observation sheets were entered into a Microsoft Excel spreadsheet, then statistically processed using SPSS 16.0. The numerical variables on subgroups defined by qualitative variables were compared by using ANOVA test. The homogeneity of variances was checked by using Levene test. In cases where this condition was not met, to evaluate the same phenomenon we used the nonparametric Kruskal-Wallis alternative for rank comparison. We sought evidence of biological clinical features suggestive of a diagnosis of Toxocariasis and their correlation with IgG titer for *T. canis.*

RESULTS AND DISCUSSION

All types of clinical manifestations were statistically significantly associated with positive Toxocara determination , except for stress/panic, sweating, palpitations, headache, dizziness and weight loss. *T. canis* IgG titer of 1/100 was most commonly found in allergies, physical asthenia, feeling of constriction in the anterior cervical region, right upper quadrant discomfort, paresthesias, nervousness, and faintness; a titer of 1/50 was often associated with urticarial reactions, dysphonia, lower leg edema, pale / yellow- waxy skin.

In the patients with laterocervical adenhopathy the most common determinations were 1/100 (34.0%), followed by 1/50 (22.6%), significantly statistically different from the values of the same determinations in patients without this diagnosis (21.4% and 19.7%, respectively) (fig. 1).

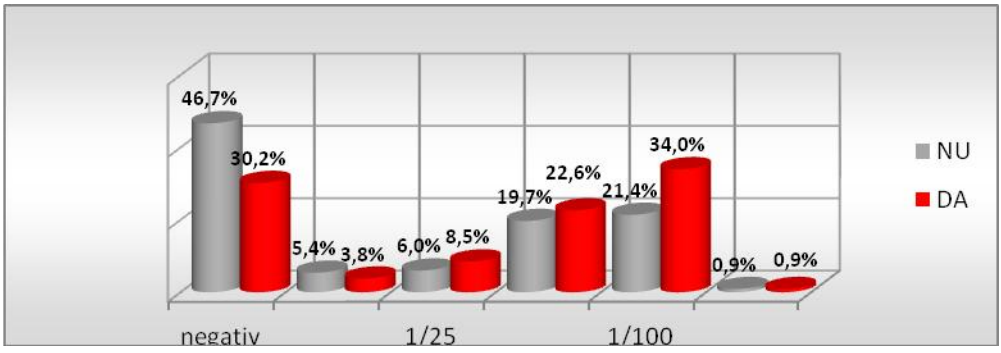

Fig. 1. *T.canis* IgG titer in the patients with laterocervical adenopathy

The sensitivity and specificity for the diagnosis of toxocariasis of the performed biochemical tests was calculated in view of identifying the tests that could lead us to this diagnosis. We determined the ROC curve and interpreted the results. For being useful in making a diagnosis of toxocariasis, the area under the corresponding curve should be greater than 0.5, ie this curve to be placed above the reference line (gray-shaded in our graph). There are tests that can actually calculate with some significance the difference from the 0.5 value of this surface (fig. 2).

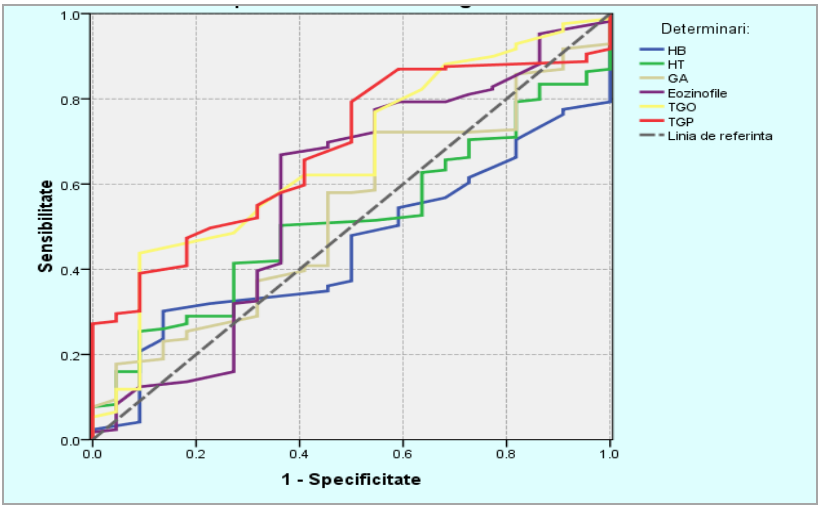

Fig. 2. ROC curve for the identification of the diagnosis of Toxocariasis

Then we calculated the area under the curve and tested the difference between this and the 0.5 threshold value. By analyzing the sensitivity and specificity for the diagnosis of toxocariasis of the performed blood tests and ROC curve calculations, we found out that the only important determinations were SGOT and SGPT, covering an area under the curve of 0.661 and 0.681, respectively, significantly greater than the 0.5 limit surface (tab. I).

Likelihood ratio tests were used to analyze the effect of each independent variable on the system; basically, we checked if each of the performed blood tests had a role in making the diagnosis.

TABLE I
Sensitivity and specificity of biological parameters

Determination	Surface	Standard error	Signif. asimpt. p	Asymptotic confidence interval 95%	
				Lower limit	Upper limit
HB	**.452**	**.054**	**.463**	**.347**	**.557**
HT	**.513**	**.055**	**.841**	**.406**	**.620**
GA	**.534**	**.062**	**.601**	**.414**	**.655**
Eosinophils	**.581**	**.072**	**.216**	**.440**	**.722**
SGOT	**.661**	**.059**	**.014**	**.545**	**.778**
SGPT	**.681**	**.052**	**.006**	**.580**	**.783**

Tests with a significance level less than 0.05 have influence on the model – this being the case of SGPT test - which has also been identified as important for determining the presence of Toxocara diagnosis by ROC curve method. Other determinations seem to have no influence on the model.

CONCLUSIONS

The clinical signs and symptoms found statistically significant can be a starting point for making a diagnosis of toxocariasis. Nonspecific laboratory findings are hyperleukocytosis, hyper-eosinophilia, and low hematocrit level, and elevated transaminase levels have high sensitivity and specificity. Accurate diagnosis is established by determining *T. canis* specific IgG and detection of *Toxocara* larvae in biopsy tissues.

THE INTERACTION BETWEEN OXIDATIVE AND NITROSATIVE STRESS IN NOCICEPTIVE PROCESSING IN RAT (Abstract): During the last years, special emphasis was directed towards the relation between the molecular and cellular alterations produced by free oxygen radicals and the normal and pathologic implications of nitric oxide. Moreover, lately it is believed that a true radical cascade might exist between the reactive species of oxygen and nitrogen during stress of various causes. In this way, their succession would produce a temporal prolongation of the complex cellular alterations produced by stressing aggressions. In the present paper, we were interested in presented some selective aspects regarding the interactions between oxidative and nitrosative stress in the modulation of the nociceptive behavior in rats. We report here a significant correlation between the results of the hot-plate latency time and the values of some oxidative and nitrosative stress markers. **Key words:** OXIDATIVE STRESS, NITROSATIVE STRESS, NOCICEPTION

Researches carried on in the last two decades with more and more advanced technical means, starting from the level of the entire organism continuing to a cellular and molecular level, have established that during the exaggerated oxido-reductive energogenic reactions there are made up variable quantities of free radicals of oxygen, generating multiple biochemical alterations, generically called oxidative stress (1).

In normal conditions of rest, the molecular oxygen, as a strongly oxidant element which is indispensable to the cellular energetic metabolism, suffers processes or bivalent reduction by the capture of two electrons with the participations of the mitochondrial respiratory chain, represented by the system cytochromes - cytochrome oxidase. Only small quantities (of 2-3%) of the molecular O_2 reaching the cellular level "escapes" from the bivalent mitochondrial oxidative-reductive reactions and take part to the process of univalent partial reduction by a single electron for making up the superoxide anion ($O_2\bullet$), as a precursor of the radical reactions producing hydrogen peroxide (H_2O_2 – oxygenated water), hydroxyl radicals ($HO\bullet$) and singlet oxygen ($1O_2$).

The intensity of the univalent reduction making new reactive species of O_2 depends both on the activation of pro-oxidant enzymes of the type of NADPH-oxidase, xanthine oxidase and myeloperoxidase, and on the participation of the means of endogenous anti-radical counteraction and defense, represented by the antioxidant enzymes – superoxide dismutase (SOD), catalase and glutathione-peroxidase (GPX) (2, 3).

Being much more reactive than the molecular O_2 reduced on bivalent way, the radical species of the oxygen determine the holding or the dislocation of some molecular components of lipids, proteins and cellular nucleoproteins (DNA, RNA), producing multiple tissue injuries, mainly cardiovascular and cerebral ones (4-6).

Disequilibria created by the oxidative stress by the predominance of the radical species of O_2 on the activity of antioxidant enzymes contribute on functional plan both to the modulation of some physiological reactions and to the genesis and evolution of different pathologic conditions.

One of these is represented by pain. Pain as complex psycho-sensorial cerebral-spinal phenomenon, having as a basis the integration and modulation of nociceptive information existent both at the level of the posterior cusp of the spinal marrow and at the level of the spinal-thalamic-cortical supraiacent structures, is one of the most common cause of human suffering generating stress. Concomitantly with the specific sensorial, perceptual, affective and behavioral manifestations, pain releases non-specific neuro-endocrino-metabolic disequilibria, similar to the other types of stressing aggressions inducing the oxidative and nitrosative stress (7).

Generally, the variable reactivity to pain and stress is based both on the multiple individual features of the cerebral chemical mediators, of the type of opioid neuropetides (endorphins, enkephalins, dinorphins), and on the genic substratum at the level of the cortical-subcortical polyneural matrix, recently described under the denomination of „Body-self neuro-matrix" (8).

Depending on the genetic substratum and on the previous experience, the central cortical-subcortical structures evaluate and release individual reactions of different intensities and durations, depending on the constitutional type, on the features of stressing aggression and on the capacity of adaptation of the subject.

Furthermore, recently, more and more studies remind of the implications of the oxidative and nitrosative stress in the nociceptive processes. As a matter of fact, in the last years, a special attention is given to the relations between the cellular and molecular alterations produced by the free radicals of O_2 and the normal or pathological implications of the nitric oxide (NO). This results from the oxidation of the terminal azoth of the amino-acid L-arginin on the shunted course of the cycle of urea, under the influence of one of the three isoenzymes of nitroxide sintetase (constitutive NOS calcium dependent), which is present in almost all the tissues and organs (9).

On a functional plan, it was proved that NO, as the free radicals of O_2, possesses dual biological properties, depending on concentration and on the individual reactivity. In small physiological concentrations, NO contributes to fix the local vasodilatation, the cardiovascular and cerebral circulation, to platelet aggregation and to antiproliferative and protective action against bacterial and viral infections. The multiple biological properties of NO are achieved both by the mechanism of activating the

guanilatcyclase forming the cyclical GMP, as an intracellular main secondary messenger, and by nitrosation of proteins forming oxidant nitrosotiols of some amino-acids (cysteine, methionine, glutathione, tyrosine) (10).

In this context, in the present study we have intended to describe the possible relations that establish between the oxidative stress and the nitrosative one in the modulation of the nociceptive processes. These aspects shall be proved by the use of a model of induced pain and by the administration of angiotensin II, of which was initially proved to detain a hyperalgesic role, as well as the use of an experimental model of stress by contention in rats, followed by the determination of some markers of the nitrosative/oxidative stress and the determination of correlations that occur between these markers and the indices of the painful perception.

MATERIAL AND METHODS

Experiments were carried on lots of male *Wistar* rats, with an average weight of 230-250 g, kept in normal laboratory conditions (constant temperature of 21˚C ± 2˚C, food and water *ad libitum*, alternating lighting regime – 12 hours light – 12 ore dark). The experimental techniques that were used have been in compliance with the international regulations regarding the work on laboratory animals.

Techniques of Neurosurgery

For the purpose of the stereotaxic intervention, *Wistar* rats were anesthetized, by intraperitoneal injection (i.p.) with a solution of Nembutal (45 mg/ kg b.w.) (Sigma). The heads of animals were fixed in the stereotaxic device so that the plan that passes through the auditory channels and the back of incisors to form an angle of 11°. Angiotensin II has been administered (3 consecutive days, 0.1µg/kg b.w.) by a plastic cannula (Portex, with the diameter of 0.44), stereotaxically implanted in the left ventricle, with the following coordinates: 0.5 mm posterior to the bregma; 1.3 mm laterally to the median line; 4.3 mm ventrally of the surface of the cortex.

The false-operated animals have been injected with physiological serum, the behavioral testing starting 7 days after the treatment.

Hot-plate test

The investigation of painful sensitivity was achieved by means of the hot-plate test. For this test, rats were placed in a closed cylindrical space, provided with an electrically hot plate and maintained constant at the temperature of 55ºC with the aid of an ultrathermostat. The hot plate produces two behaviors and their times of reaction can be measured: paw licking and the bounce.

Stress of contention

Stress of contention consists in the immobilization of the animal for 30 minutes. In this manner, it was considered that the stress of contention is one of the most repeatable experimental protocols, with the possibility of minimizing the implied variables and which in the same time presents enough similarities with the other types of nociceptive stress.

Determination of the markers of the oxidative and nitrosative stress was carried on as described above (6, 7). As the **statistical analysis of data is concerned**, it was used ANOVA one-way (the values of $p \leq 0.05$ have been considered significant) for the results of the behavioral tests and the Pearson correlations in order to establish the relations between the markers of the oxidative/nitrosative stress and the

behavioral indices.

RESULTS

As mentioned above, the administration of angiotensin II has determined a significant decrease (F (1.8)=13, p=0.006) of the time of latency for the hot-plate test, related to the witness lot (fig. 1), fact that suggests the nociceptive effects of angiotensin II.

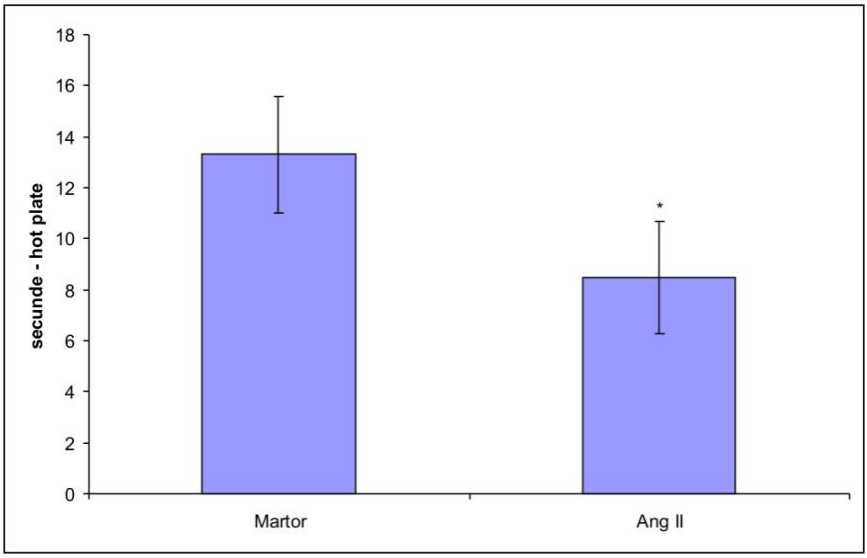

Fig. 1. The effects of administrating Ang. II on the time of latency of hot-plate.
The results are expressed by average ± E.S.M. (n=5).
*p=0.006 compared to the control.

Furthermore, we have noticed a significant correlation between these effects and the levels of some different markers of the oxidative stress that were previously determined (11). In this way, as the relation between the time of latency of hot-plate vs. the specific activity of superoxide dismutase (SOD) are concerned, the Pearson correlations have shown an r = - 0.798 and a p of 0.006, for n= 10 (fig. 2). In the same manner, in the case of the second determined antioxidant enzyme have been noticed significant correlations with the time of latency in the hot-plate (n=10, r = - 0.541, p=0.045) (fig. 3). Moreover, we have obtained significant correlations between the level of lipidic peroxidation (shown by the concentrations of MDA) vs. the time of latency (n=10, r=0.857, p=0.002) (fig. 4).

As the level of markers of the nitrosative stress is concerned, it was opted for the determination of the nitrite anion (NO_2^-), considering that this is the main mediator in the reaction of nitrosylation of the tyrosine amino-acids in the structure of different proteins, this reaction representing the foundation of the phenomenon of nitrosative stress. In this case was also noticed an important correlation with the behavioral processes, considering the decreased level of NO_2^- after those 30 minutes of stress of contention (F(1,8)=60, p<0.0001), compared to the witnesses (fig. 5).

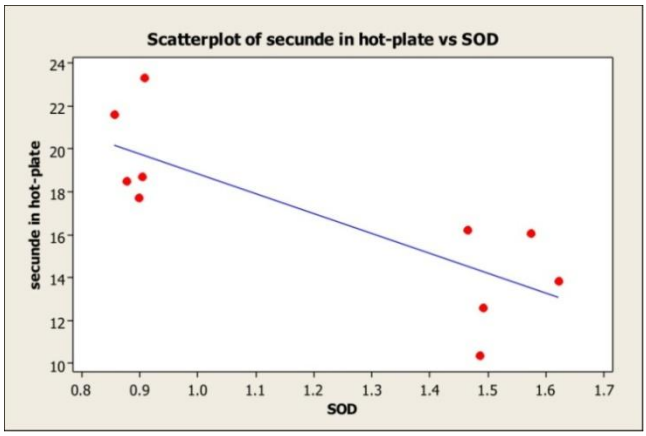

Fig. 2. The degree of correlation between the time of latency in the hot-plate and SOD.

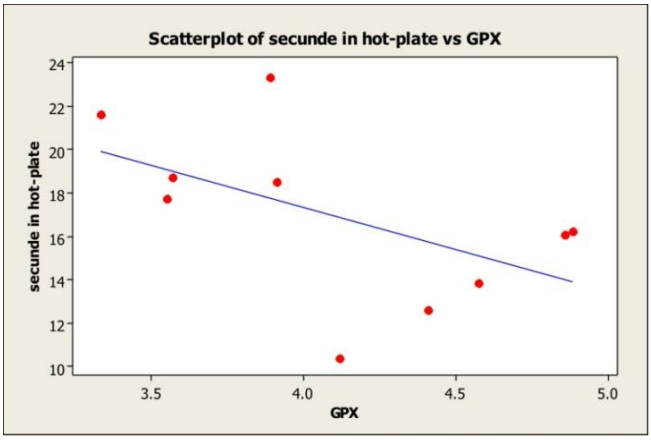

Fig. 3. The degree of correlation between the time of latency in the hot-plate and GPX.

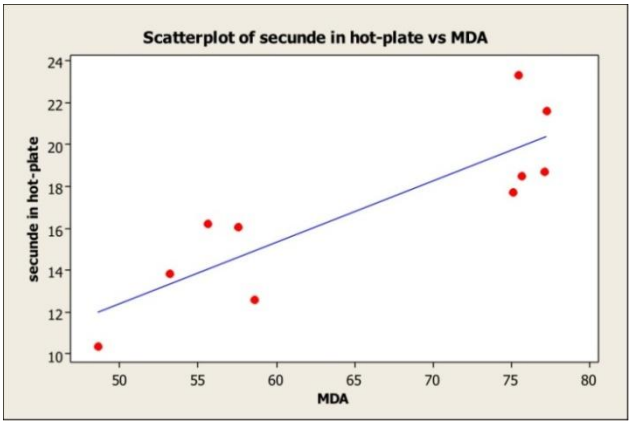

Fig. 4. The degree of correlation between the time of latency in the hot-plate and MDA.

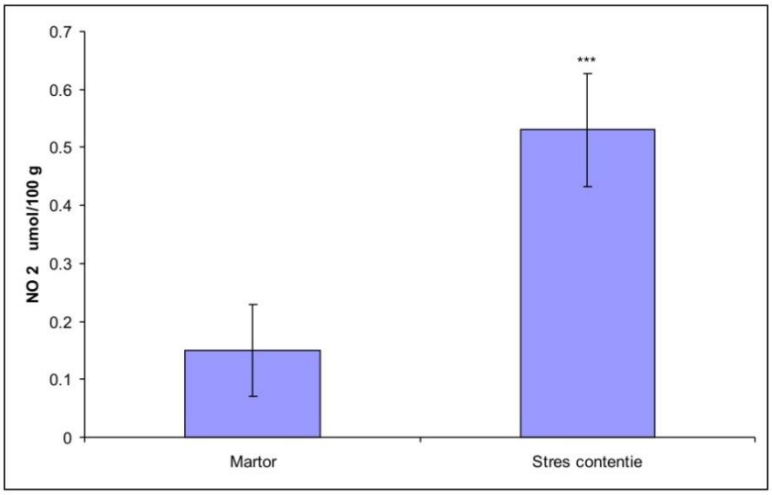

Fig. 5. The effects of the contention stress on the levels of NO_2^-. Results are expressed by average ± E.S.M. (n=5). *** $p < 0.0001$ compared to the control.

DISCUSSION

In the present study we have confirmed the existence of some relations between the oxidative stress and the nitrosative one in the modulation of the nociceptive processes, by the use of a model of pain induced by the administration of angiotensin II, as well as by the use of an experimental model of stress by contention in rats, followed by the determination of some markers of the nitrosative/oxidative stress and proving the correlations that occur between these markers and the indices of the painful perception.

In this manner, previous studies have proved the involvement of angiotensin II in the modulation of the nociceptive perception. Therefore, Kaneko and collaborators have proved that the intracerebroventricular administration of angiotensin II has led to the diminishment of the analgesia induced by the initial administration of morphine (12). Also, it was proved that the administration of some inhibitors of the conversion enzyme, as well as of some antagonists specific for angiotensin II lead to the diminishment of nociceptive responses in specific tests such as the hot-plate test (13). Similarly, in the case of the present paper we have proved that the administration of angiotensin II determines a significant decrease of the time of latency for the hot-plate test, compared to the witness lot, fact that suggests its nociceptive effects.

Moreover, in the present article we have reported a direct correlation between the above-mentioned effects in the behavioral tests of pain (hot-plate) and the markers of the oxidative stress, represented by two enzymes with antioxidant effect (SOD and GPX), as well as of a marker of the processes of lipidic peroxidation (MDA).

Also, there was presented a possible relation between an important marker of the stress (NO_2^-) and the stress of contention (it was considered that the stress of contention is one of the most repeatable experimental protocols, with the possibility of minimizing the implied variables and which in the same time presents enough similarities with the other types of nociceptive stress). Further-

more, nitrite anions are the main mediators in the reaction of nytrosilation of the tyrosine amino-acids in the structure of different proteins. This reaction represents the basics of the phenomenon of nitrosative stress and as a result, the variations of concentration of these radicals are direct witnesses of the nitrosative stress. Therefore, from a statistical point of view, there was a significant increase of the quantity of nitrite anions, fact that is an incontestable proof in the favor of the occurrence of the nitrosative stress at the level of the nervous system of animals subjected to the stress of contention.

Therefore, the nociceptive stress produces modifications at the level of the central nervous system, of oxidative and nitrosative type, modifications that can variably affect the capacity of transmission and perception of nociceptive signals by the animal of experience. Moreover, these data seem to suggest the fact that the intraneural and/or extraneural effects of modification of proteins involved in the phenomena of transduction of the painful signal are truly due to the effects of the presence of mediators of the nitrosative stress, which are in increased quantities.

As a matter of fact, it is considered that a real radical cascade would produce between the reactive species of the oxygen, azoth and newly of the carbon during the stress having different causes (14, 15). Their succession would realize amplification and implicitly the prolongation in time of the complex cellular disorders produced by the stressing aggressions, such as those related to nociception. Also, on a pharmacotherapeutic plan there occur differences between the three categories of radical species involved in stress: while the oxidative component of the stress benefits of antioxidant therapy based on the high consumption of vitamins C, A and E, beta-carotene, flavonoids, selenium, polyphenols, anthocians and procyanidins, fighting the stress caused by pain situates to the fore the adequate analgesic, anxiolitic and hormonal medication with glucocorticoids or non-steroidal inhibitors of the cyclo-oxigenases of the type of indomethacin, diclophenac, ketoprophen or celebrex in the case of the inflammatory pain (16-18). Moreover, new therapeutic opportunities open the clinical-experimental researches referring to the neurosedative and anti-stressing properties of melatonin or inhibitors of receptors of the hypothalamic CRF (Corticotropin Releasing Factor) and the rennin-angiotensin cerebral system (19, 20), discussed in the present paper.

Although these studies show the involvement of the free radicals in different nociceptive mechanisms, much more detailed studies are necessary for the independent replication of these results and the use of the proper antioxidants as a treatment, having in regard the complexity of the biochemical systems and numerous interactions between the antioxidant and the prooxidant molecules from the biological processes.

CONCLUSIONS

In this study we have confirmed the existence of some relations between the oxidative stress and the nitrosative one in the modulation of the nociceptive processes, by the use of a model of pain induced by the administration of angiotensin II, as well as by the use of an experimental model of stress by contention in rats, followed by the determination of some markers of the nitrosative/oxidative stress and proving the correlations that occur between these markers and the indices of the painful per-

ception. These aspects could have a special importance in the therapy of different mechanisms of nociception.

CONTRIBUTIONS TO THE METHODOLOGY OF STUDY IN THE FUNCTIONAL ASSESSMENT OF TEMPOROMANDIBULAR JOINT DYSFUNCTIONAL SYNDROME (Abstract): **Aim:** Dysfunctional syndrome of the temporomandibular joint through the complexity and variability of the symptoms may result in significant structural and functional changes leading from discomfort to disability and a negative impact on quality of life. **Materials and methods:** A prospective study was conducted between October 2009 - December 2010, in 52 subjects diagnosed with rheumatoid arthritis and complaining of symptoms in the temporomandibular joint. The functional examination of the joint and muscle has included the assessment of the active range of motion, passive range of motion, resistance range of motions of the temporomandibular joint, dermatomes and the pain in the region of masseter, temporalis, median and lateral pterigoids, digastric, sternocleidomastoid and longus colli muscles. The ultrasound examination has included clinical aspects of alignment, shape, dynamics of the mandibular condyle, of the temporal fossa, aspects regarding the temporal and masseter muscles at rest and at contraction phases. **Results**: The clinical examination highlighted the presence of pain at temporomandibular jointlevel for all tested pacients. The majority complained the pain from moderate to severe level. For the majorityof cases(59,60%) the pain stars spontaneously, during the day time (80,80%) and the night time(50,60%). Over 50% from the research cases complained cracks at the temporomandibular joint level released by a movement. At the oral and dental examination of the research group 55,8% from the tested pacients presented dental cavities toothless partially or totally duet o additionally overworking temporomandibular joint. The limitation of the range of motion is not the most important detected dysfunction, affecting approximately 30% of the cases that have been studied. Pain and spasm in a very large proportion are present in the masseter and temporal muscles regions. Atrophy is present in a lesser extent. The dysfunctional index shows an involvement of the temporomandibular joint, for over 45% of patients tested. The ultrasound examination revealed degenerative inflammatory lesions at a rate of 38.46%, inflammatory lesions at a rate of 28.85% and mixed lesions at a rate of 9.62%.**Conclusions**: The research regarding the clinical paraclinical and functional aspects of temporomandibular joint, permited to highlight the fact that rheumatic inflamatory and degenerative, pathology, characterises it self through a high index of morbidity and disability that lowers the life quality. Establishing a treatment plan involves customizing all clinical, functional and laboratory data.
Key words: TEMPOROMANDIBULAR JOINT, DYSFUNCTIONAL SYNDROME, FUNCTIONAL ASSESSMENT

Mişcarea reprezintă principala funcție pe care o realizează omul şi datorită căreia acesta beneficiază de independență şi se integrează în mediul înconjurător. Articulația temporo-mandibulară (ATM) este o articulație complexă, specială sub raport morfologic şi funcțional (1). Problematica controversată generată de sindromul algodisfuncțional al ATM reține interesul practicienilor şi cercetătorilor din mai multe domenii.

Terapia prin mişcare, utilizând procedeele non-invazive poate ameliora simptomatologia din sindromul algodisfuncțional al articulației temporo-mandibulare modificând viziunea pacienților în legătură cu afecțiunea de care suferă.

OBIECTIVE

Cercetarea noastră are ca obiectiv evidențierea incidenței sindromului algodisfuncțional în rândul populației cu boli reumatismale prin evaluări obiective clinice, funcționale şi paraclinice.

Scopul principal este de a sensibiliza personalul medical şi a conştientiza pacienții de resursele şi importanta tratamentului kinetic în combaterea durerii şi menținerea unei funcționalități favorabile la nivel cranio-facial.

MATERIAL ŞI METODE

Studiul prospectiv realizat în perioada octombrie 2009 - decembrie 2010 a inclus un lot de 52 de pacienți şu afectări reumatice inflamatorii şi degenerative

Informațiile au fost obținute pe baza unui chestionar cu referire la durere, zgomote articulare temporo-mandibulare, dificultăți şi rigiditate la mişcarea mandibulei, obiceiuri vicioase, antecedente şi tratamente efectuate.

De asemenea, bolnavii au fost evaluați pe baza unei fişe ce acuprins: datele anamnestice generale; evaluarea clinică realizată in colaborare cu medicul curant; examinarea funcțională articulară (testarea mişcărilor active de deschidere şi închidere a gurii, lateralitate, protuzie, retruzie menționându-se amplitudinea de mişcare, existența deviației, restricției sau durerii in realizarea lor, mişcările pasive (*end-feel*-ul), mişcările cu rezistență, mişcările de joc articular la nivel temporo-mandibular pentru parametrii menționați anterior); examinarea musculaturii mobilizatoare a mandibulei şi a celei cervicale realizată prin palpare digitală, pentru determinarea contracturii musculare şi a durerii la nivelul muşchilor maseter, temporal, pterigoid intern şi extern (fig. 1), digastric, sterno-cleido-mastoidian şi lungul gâtului (2); examinarea paraclinică ecografică a urmărit aspecte legate de alinia-

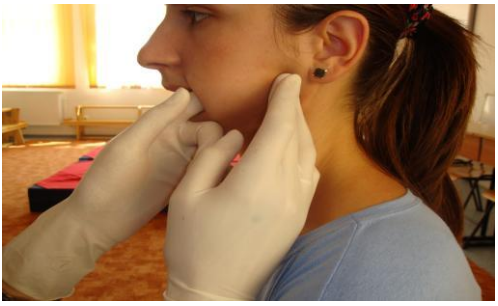

Fig. 1. Testarea muşchiului pterigoid extern

ment, formă, dinamică a condilului mandibulei, aspecte ale formei fosei temporale, ale spațiului intrarticular în repaus şi dinamică (fig. 2) (1,2), aspecte ale meniscului legate de starea de repaus şi contracție ale muşchilor temporal şi maseter; examinarea s-a realizat cu o sondă de 3,5MHz, cu pacientul în decubit dorsal cu transductorul plasat paralele cu lungul ax al mandibulei.

Pe baza parametrilor obținuți la testarea clinică generală, testarea articulară şi testa-

rea musculară am evaluat disfuncţia la nivelul ATM prin intermediul unui indice cu scorul de afectare maximă 30.

Fig.2. Ecografie ATM calcificare meniscală

REZULTATE ŞI DISCUŢII

Distribuţia pe sex a pacienţilor incluşi în studiu a evidenţiat existenţa unor date similare cu cele publicate de alţi autori (5, 6).

Deşi a predominat afectarea sexului feminin, s-a remarcat totuşi o incidenţă moderat crescută la pacienţii de sex masculin cu boală artrozică în comparaţie cu cei cu afectare reumatoidă (fig.3).

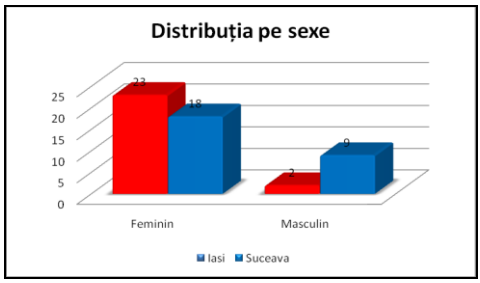

Fig. 3. Distribuţia cazurilor pe sex

În ceea ce priveşte durata de evoluţie a bolii reumatismale de bază, s-a constat prezenţa atât a bolnavilor cu debut recent cât şi a celor cu un istoric de peste 21 ani. Afectarea articulaţiei temporo-mandibulare a dovedit a avea o durată mai scurtă, aspect vizualizat şi de media de vârstă a bolii de bază comparativ cu cea a afectării temporo-mandibulare (tab. I).

În urma analizei corelaţiei dintre vârsta pacienţilor şi durata afecţiunii lor de bază s-a constatat o relaţie cu intensitatea medie, cu semnificaţie statistică, coeficienţii Pearson şi Spearman prezentând valoare de 0,605.

TABELUL I

Durata de evoluţie a bolii de bază şi temporo-mandibulare

Durata Afectării	Nr.	Media de vârstă	Min	Max	Deviaţia Standard	Semnificaţia Mediei
Vârstă(ani)	52	56,36ani	27	79	12,831	1,546
Boala bază	52	9,74 ani	0,5	21	5,464	1,051
ATM	52	3,58 ani	2	13	2,474	0,476

În ce priveşte relaţia dintre vârsta pacienţilor şi durata afectării secundare s-a evidenţiat că intensitatea acestei legături scade din punct de vedere statistic, cei 2 indicatori de corelaţie calculaţi au de această dată valori mult mai mici ceea ce indică o semnificaţie slabă (0,306 respectiv 0,486).

Explicaţia este legată de faptul că afectarea temporo-mandibulară poate fi sau nu prezentă în cadrul bolii de bază şi poate apare în orice perioadă evolutivă a acesteia.

Examenul clinic a evidenţiat existenţa durerii la nivel temporo-mandibular la toţi pacienţii testaţi. Majoritatea au prezentat o intensitate moderată sau severă, fiecare

categorie având valori de 42,30% (tab. II).

TABELUL II
Intensitatea durerii – Scala analogă vizuală-VAS

Intensitate (VAS)	Nr	%(x)
Fără durere (0-1)	0	0
Durere uşoară (2-3)	6	11,53
Durere moderată (4-5)	22	42,30
Durere severă (6-7-8)	22	42,30
Durere insuportabilă (9-10)	2	3.87

(x) Pentru valori mai mici de 10 proporţiile sunt orientative

La pacienţii luaţi în studiu durerea a fost simţită în diferite circumstanţe: la palparea conductului auditiv extern sau a pretragusului, în timpul masticaţiei, la mobilizarea mandibulei sau la palparea muşchilor masticatori.

În majoritatea cazurilor (59,60%) durerea apare spontan, diurn (80,80%) şi nocturn(50,60%).

La pacienţii cu artroză durerea a fost semnalată mai mult provocată şi diurn, iar la cei cu manifestări de tip inflamator aceasta a fost de obicei spontană şi cu intensificare nocturnă. Este important de evaluat şi diagnosticul bolii de bază deoarece determină caracterul durerii şi prognosticul afecţiunii.

Peste 50% din cazurile noastre au prezentat zgomote la nivelul articulaţiei temporo-mandibulare declanşate de angajarea unei mişcări; fiind considerate semne majore ale disfuncţiei temporo-mandibulare posibil a exprima o situaţie anormală indusă de leziunile articulare. Cu cât stadiul bolii de bază este mai avansat cu atât prezenţa zgomotelor intrarticulare este mai frecventă.

La evaluarea orală şi dentară a lotului de studiu s-a dovedit a fi manifestări importante ce pot determina în timp, disfuncţionalităţi la nivelul articulaţiei temporo-mandibulare.

În cazul nostru 55,8% din pacienţii evaluaţi au prezentat carii dentare şi 38,5% edentaţii parţiale sau totale, afecţiuni care solicită suplimentar articulaţia temporo-mandibulară.

Cercetările noastre au constatat că amplitudinea de mişcare la nivel temporo-mandibular era deteriorată în proporţie variabilă în funcţie de tipul mişcării: 15,38% pentru deschiderea gurii, 29,9% de lateralitate, 21,15% de protuzie, 1,92% de retruzie. Limitarea mişcării a înregistrat valori totale de sub 30%.

Testarea musculară s-a realizat pentru muşchii maseter, temporal, pterigoid intern, pterigoid extern, digastric, sternocleidomastoidian sau lungul gâtului şi a urmărit existenţa durerii, spasmului şi atrofiei. Durerea într-o proporţie foarte mare este prezentă la nivelul muşchilor maseter (84,61%) şi temporal (65,38%), (principalii muşchi masticatori), iar într-o proporţie moderată la ceilalţi muşchi testaţi.

Spasmul este însoţit sau generat de durere a fost prezent într-o proporţie de 51,91% la nivelul maseterului, 26,92% a temporalului, 13,46% a pterigoidului intern şi extern şi 17,30% la nivelul sterno-cleido-mastoidianului.

Cu ajutorul valorilor acordate fiecărei disfuncţionalităţi s-a estimat evoluţia indicelui ATM astfel a rezultat o medie de 13,56 ceea ce denotă o afectare temporo-mandibulară de peste 45% la bolnavii aflaţi in studiu.

Examinarea ecografică a permis depistarea leziunilor la nivelul articulaţiei temporo-mandibulare contribuind astfel la confirmarea diagnosticului clinic (fig. 4).

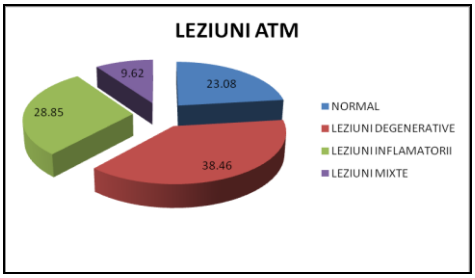

Fig. 4. Ponderea leziunilor ATM depistate ecografic

La evaluarea paraclinică ecografică s-au depistat leziuni degenerative în proporţie de 38,46% (demineralizări ale condilului şi ale fosei, osteofite, eroziuni marginale, diminuarea spaţiului articular); leziuni de tip inflamator în proporţie de 28,85% (contur dinţat şters al condilului mandibular şi fosei temporale, osteoporoză, geode, lichid sinovial, calcificări meniscale, mobilitate limitată a condilului) şi leziuni mixte (9,62%).

În cazul a 23,08% pacienţi au lipsit leziuni ecografice evidenţiate la nivelul articulaţiei temporo-mandibulare.

Investigaţia ecografică a muşchilor maseter şi temporal în repaus şi în contracţie determinarea grosimii muşchiului în cele două faze (tab. III).

TABELUL III

Evaluarea ecografică la nivel muscular

Niveluri	Muşchi							
	Temporal				Maseter			
	Repaus		Contracţie		Repaus		Contracţie	
	D	S	D	S	D	S	D	S
Media	6,53	6,50	8,03	8,02	8,57	8,61	10,44	10,50
Max	8,5	7,9	10	9,3	10,2	11	13	13
Min	4,9	5,4	6	6,3	6	6,4	7,3	8
DS	0,724	0,584	0,810	0,641	0,783	0,787	0,940	0,793
Correl	0,719		0,721		0,909		0,859	

În urma analizei statistice a corelaţiei dintre valorile musculare din parte dreaptă şi stângă se poate concluziona că există o legătură de intensitatea mare din punct de vedere statistic, coeficientul obţinut pentru muşchiul temporal-în repaus este de 0,719; coeficientul obţinut pentru muşchiul temporal-în contracţie este 0,721; coeficientul obţinut pentru muşchiul maseter-în repaus 0,909; coeficientul obţinut pentru muşchiul master în contracţie 0,859 (fig. 5).

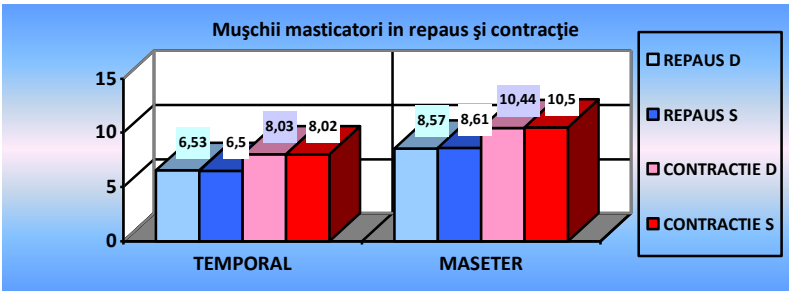

Fig. 5. Dinamica mediei în repaus şi contracţie pentru muşchii maseter şi temporal

DISCUŢII

Articulaţia temporo-mandibulară are structură particulară şi funcţii generate de sistemul cranio-facial a cărui subsegment este activitatea sa, în condiţii de articulaţie cu o parte fixă şi una mobilă, de joc funcţional concomitent bilateral şi încărcare, crează o biomecanică specială; articulaţia va înregistra mecanismele patologice ale bolilor reumatismale sistemice şi totodată va avea o patologie condiţionată de cauze locale (7).

ATM este frecvent implicată în determinarea durerii oro-faciale recunoscută pentru indicatorul de morbiditate şi dizabilitate (2). În cadrul patologiei sale, în ultima perioadă s-a particularizat sindromul algo-disfunctional la originea căruia s-au grupat trei elemente: ATM, musculatura şi structurile adiacente (6).

În practica medicală sindromul algic la nivelul ATM este recunoscut pentru impactul clinic şi epidemiologic crescut, pentru caracterul dizabilitant şi necesitatea unei abordări multidisciplinare ceea ce presupune stabilirea unui algoritm diagnostic şi terapeutic.

Studiul de faţa sensibilizează asupra acestui aspect analizând un lot de bolnavi cu boală reumatismală inflamatorie şi degenerativă şi afectare de tip sindrom algo-disfuncţional. Pentru a evalua din punct de vedre clinic şi funcţional ATM s-au utilizat o serie de parametri fizici, articulari şi musculari care au evidenţiat participarea în special a componentei musculare în generarea manifestărilor clinice şi disfuncţionale ale sindromului.

Utilizarea ecografiei în diagnosticul suferinţei (standardizată pe cuantificarea elementelor morfologice şi de dinamică a condilului) subliniază, o dată în plus, aportul diagnostic al metodei în suferinţele aparatului locomotor.

Evidenţierea indicelui de disfuncţie ATM prin măsurarea unor parametri fizici, articulari, musculari şi ecografici cu valoare medie de 13,56 exprimând o deterioare mai mare de 45% a structurilor zonale este în acord cu datele *The European Leaque Against Rheumatism* (EULAR) şi *American College of Rheumatology* (ACR) îl promovează pentru bolile aparatului locomotor, de determinare obiectivă a deficitelor.

CONCLUZII

Cercetările noastre multidisciplinare privind aspectele clinice, paraclinice şi funcţionale a articulaţiei temporo-mandibulare au permis a se evidenţia că patologia reumatică inflamatorie şi degenerativă se caracterizează prin indici de morbiditate şi dizabilitate crescuţi, ceea ce degradează calitatea vieţii.

Afectarea articulaţiei temporo-mandibulare la pacienţii cu reumatism inflamator şi degenerativ amplifică suferinţa clinică şi dizabilitatea bolnavului.

Examenul funcţional a evidenţiat limitarea amplitudinii pe anumite direcţii de mişcare şi afectarea grupurilor musculare adiacente articulaţiei temporo-mandibulare.

Investigarea paraclinică a oferit argumente care demonstrează deteriorarea morfologică şi funcţională a ATM, examenul ecografic dinamic având o putere de diagnostic mare oferind condiţii optime de evaluare a cost - eficienţei unei terapeutici optime, efectuate concomitent cu investigaţiile funcţionale şi paraclinice.

Programul terapeutic personalizat presupune analizarea datelor referitoare la aspectele clinice, funcţionale şi paraclinice precum şi sinteza tuturor indicilor clinico-biologici, funcţionali, socio-economici şi psiho-comportamentali ai pacientului.

NOUTĂŢI

p53 MUTANT - ŢINTA TRATAMENTULUI ANTITUMORAL

Un nou studiu descrie un compus care distruge selectiv celulele canceroase prin restaurarea structurii şi funcţiei uneia dintre proteinele care suferă cel mai frecvent mutaţii în cancerul uman, supresorul tumoral p53. Gena care codifică p53 a suferit mutaţii în mai mult de jumătate din cazurile de cancer uman, şi pierderea funcţiei p53 a fost legată de multe aspecte, inclusiv de agresivitatea cancerului, metastazarea şi răspunsul slab la chimioterapie şi radiaţii. Restaurarea funcţiei p53 mutant cu un medicament reprezintă o strategie terapeutică atractivă în cancer, cu toate acestea, s-a dovedit a fi dificil să se găsească compuşi care restabilesc funcţia pierdută a unui supresor tumoral defectuos. Dr. Alexei Vazquez, a dezvoltat o metodă computerizată de screening pentru a identifica compuşi care au ca ţintă celulele tumorale cu mutaţii p53, dar nu şi celule p53 normale. Metoda de screening a implicat celulele canceroase, cu genotipuri diverse şi a identificat doi compuşi din familia tiosemicarbazonă care au ucis celulele canceroase care conţin p53 mutant prin restaurarea structurii şi funcţiei unei mutante p53-R175H. Aceste cercetări susţin tendinţa dezvoltării unor terapii antitumorale pe baza cunoaşterii genotipului tumorii pacientului. Xin Yu, Alexei Vazquez, Arnold J. Levine, Darren R. Carpizo. Universitatea de Medicină şi Farmacie „Grigore T. Popa" - Iaşi,
Facultatea de Medicină
3. Disciplina de Asistență Primară a Stării de Sănătate şi Epidemiologie

CLINICAL EPIDEMIOLOGICAL CHARACTERISTICS OF PATIENTS WITH GASTRIC CANCER IN EMERGENCY MUNICIPAL HOSPITAL MOINESTI (Abstract): Cancer is now a major public health problem by the size of the human, medical, economical and social implications as well as in industrialized and also in developing countries. Gastric cancer is a neoplasia with a starting point in gastric mucosa, representing one of the most common malignant visceral locations, being on the second most common after lung neoplasm. **The aim** is to highlight the incidence of gastric cancer in Emergency Municipal Hospital in Moinesti in relation with certain factors (age, sex, area of origin, personal habits, personal and family pathological history) for a period of eleven years. **Material and methods:** The study has been conducted on a period of eleven years (2000-2010) and it included 77 patients with gastric cancer. The following parameters were evaluated: age, sex, area of origin, personal habits, personal and family pathological history. **Results:** Distribution by years of study revealed that most of the cases were in 2009 (19 patients). The incidence of gastric cancer was over two times higher at men than at women, the ratio men/women being 2,34 to 1. The most common cases (n=40) were reported in people over 61 years (the mean age was 60,32±11,87) and from rural areas (ratio rural/urban areas=1,5:1). Only 15 patients (19,5%) had in the personal antecedents stomach or duodenal ulcer and half of the cases were smokers (49,35%). **Conclusion:** The profile of patient with gastric cancer was contoured: male, over 60 years, from rural areas, smoker and with a personal history of stomach or duodenal ulcer. **Key words:** HEALTH PROBLEM, GASTRIC CANCER, INCIDENCE.

Cancerul gastric (CG) este o neoplazie cu punct de plecare în mucoasa gastrică, reprezentând una dintre cele mai frecvente localizări viscerale maligne, situându-se pe locul al doilea ca frecvență, după neoplasmul bronhopulmonar (1, 2).

Cu largă răspândire la nivel mondial, CG are o variabilitate importantă de la o țară la alta, atât ca morbiditate cât şi ca letalitate. În Europa, rata de incidență la bărbați este mai mare în est (29,6/100.000) şi în sud (18/100.00), față de femei în nord (5,9/100.000) şi în vest (6,6/100.000) (3-5). Grupul de vârstă cel mai afectat de CG este între 50-70 ani, cu o ascensiune în jur de 60 şi foarte rar sub 30 ani (6), iar frecvența

bolii la populația masculină este dublă în raport cu cea feminină (7).

Lucrarea își propune realizarea unui studiu epidemiologic, retrospectiv, descriptiv pentru evaluarea incidenței cazurilor de CG asistați în Spitalul Municipal de Urgență Moinești, pe o perioadă de unsprezece ani, în raport cu anumiți factori (vârstă, sex, mediu de proveniență, obiceiuri personale, antecedente patologice personale și familiale).

MATERIAL ŞI METODE

Studiul realizat în perioada 2000-2010 a inclus 77 de pacienți cu CG asistați în Spitalul Municipal de Urgență Moinești.

Lotul studiat a cuprins pacienții nou diagnosticați cu CG și internați în Spitalul Municipal de Urgență Moinești. Diagnosticul a fost susținut pe baza anamnezei, examenului clinic, investigațiilor de laborator și imagistice, aspectului morfologic intraoperator și examenului anatomopatologic postoperator.

Din lotul studiat au fost excluși pacienții diagnosticați și tratați în alte spitale și cei care, deși au prezentat la internare semne și simptome ce orientau diagnosticul către CG, acesta nu a putut fi confirmat prin endoscopie cu biopsie și examen anatomo-patologic.

Datele au fost obținute atât prin studiul documentelor medicale din Spitalul Municipal de Urgență Moinești cât și prin ancheta clinico-epidemiologică.

Informațiile acumulate au fost evaluate prin metode epidemiologice și statistice (metoda de analiză dispersională ANOVA și testul „t" privind egalitatea a două medii aritmetice – metoda Kaplan Meier).

REZULTATE

1. *Distribuția anuală* a pacienților cu CG asistați în Spitalul Municipal de Urgență Moinești, a evidențiat o distribuție relativ uniformă pe durata a 11 ani, cu două ascensiuni, în anul 2005 (11 cazuri) și în 2009 (19 cazuri) (fig.1).

2. *Evaluările pe sex* au stabilit că, în întreaga perioadă, din cele 77 cazuri de CG au fost înregistrate 70% la barbati, cu un raport M/F de 2,34/1 (tab.I, fig.2).

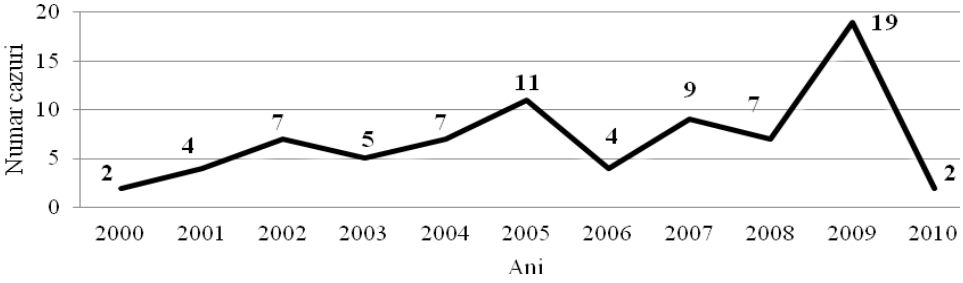

Fig. 1. Distribuția anuală a bolnavilor cu cancer gastric incluși în studiu, în perioada 2000-2010

TABELUL I

Distribuția pe sex a pacienților incluși în studiu

Sex	Nr.	%	Raport M/F
Masculin	54	70	2,34/1
Feminin	23	30	
TOTAL 77 100%			

Fig. 2. Distribuția pe sex a cazurilor de cancer gastric incluse in studiu

3. *Vârsta medie* a pacienților din lotul de studiu a fost de 60,32±11,87, variind de la 25 la 85 de ani. Extremele grupurilor de vârstă au fost cuprinse între 25 şi 85 de ani, iar grupul de vârstă 61-70 de ani a inclus cei mai multi pacienți:23 (30%) (tab. II, fig. 3).

4. *Distribuția pe medii de proveniență* a evidențiat valori de prevalență mai mari pentru pacienții proveniți din mediul rural (58,44%) (fig. 4), cu predominanța bărbaților (59,25%) (fig. 5).

TABELUL II

Distribuția pe grupuri de vârstă

Grupul de vârsta (ani)	Pacienți		Barbați		Femei (x)	
	Nr	%	Nr	%	Nr	%
<20	0	0,0	0	0,0	0	0,0
21-30	2	2,6	2	3,7	0	0,0
31-40	1	1,3	0	0,0	1	4,4
41-50	14	18,2	9	16,7	5	21,8
51-60	20	26,0	12	22,3	8	34,6
61-70	23	30,0	20	37,0	3	13,0
71-80	15	19,3	10	18,5	5	21,8
81-90	2	2,6	1	1,85	1	4,4

(x) Pentru valorile mai mici de 10, proporțiile sunt orientative.

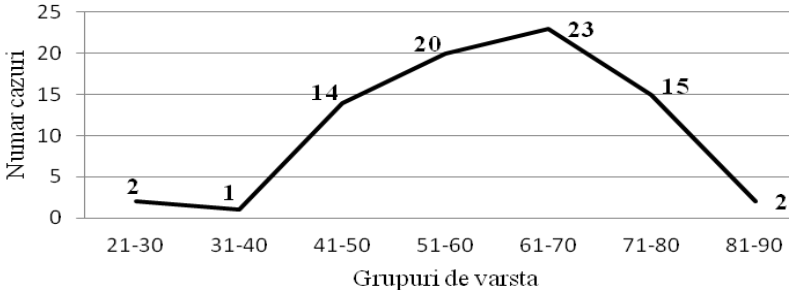

Fig. 3. Distribuția pe grupuri de vârstă a pacienților cu cancer gastric incluşi în studiu

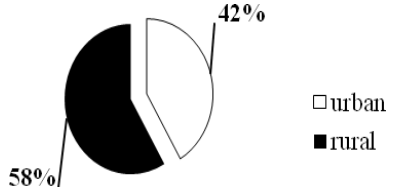

Fig. 4. Distribuția pe medii de proveniență a pacienților cu cancer gastric asistați în Spitalul Municipal de Urgență Moineşti

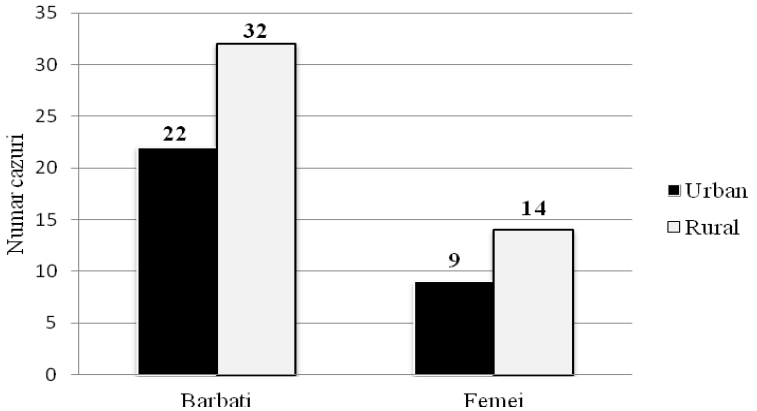

Fig. 5. Distribuția pe sex şi medii de proveniență a lotului de 77 pacienți cu cancer gastric

5. *Antecedentele heredocolaterale*. La bolnavii cu cancer gastric incluşi în studiu s-au evidențiat următoarele grupuri de afecțiuni:

- tulburări metabolice la 19 (24,67%), din care: obezitate 12 (15,58%) şi diabet zaharat 7 (9,09%)
- boli cardiovasculare la 46 (59,74%), din care cu: HTA 31 (40,25%) şi IC 15 pacienți (19,48%)
- boli digestive la 21 (27,27%), din care: ulcer gastric/duodenal 9 (11,68%) şi cancer digestiv: 12 (15,59%) (fig. 6).

6. *Antecedentele patologice personale* ale pacienților. Cercetările au constatat că doar 15 (19,5%) au prezentat ulcer gastric sau duodenal, pentru celelalte comorbidități s-au înregistrat valori între 2 şi 46 cazuri (HTA: 46; ICC: 17; adenom de prostată: 13; litiază biliară: 4; astm bronsic: 2) (fig. 7).

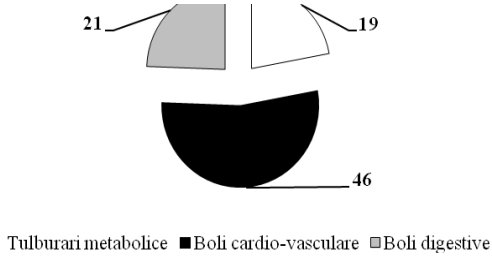

Fig. 6. Distribuția pacienților în relație cu antecedentele heredocolaterale

DISCUȚII

Analizând incidența cazurilor noi de cancer gastric în Spitalul Municipal de Urgență Moineşti în perioada 2000 – 2010 s-a remarcat anul 2005 cu 11 (14,28%) şi 2009 cu 19 (24,67%) cazuri, iar incidența cea mai scăzută a fost în anii 2000 şi 2010, cu 2 cazuri/an (2,6%). Media pe cei 11 ani de studiu a fost de 7 cazuri noi/an.

Rezultate similare cu noi au obținut şi alți autori. Astfel, Gherman et al. (8) într-un studiu pe 158 bolnavi tratați în clinica Chirurgie II din Cluj-Napoca, în perioada 1992-2002, au găsit o distributie anuală relativ omogenă a cazurilor, între 6 şi 16, cu o medie de 10 pacienți pe an.

Incidența CG în studiul nostru evaluată în relație cu sexul a fost de peste 2 ori mai mare la bărbati decât la femei: 54 (70%) cazuri pentru masculin şi respectiv 23 (30%) feminin. Raportul bărbați/ femei a fost de 2,34/1.

Valoarea raportului determinată pentru lotul studiat este în concordanță cu rezultatele cercetărilor altor autori (9,10,11) care indică o afectare mai frecventă a bărbaților decât a femeilor, atât pentru CG în general, cât si pentru cel cu alte localizari, cu un raport de aproximativ 2/1.

Evaluarea pe grupuri de vârstă a aratat că aproape 78% dintre pacienții studiați au avut vârsta peste 51 de ani. Incidența CG a înregistrat o crestere de la 2,6% la sub 30 de ani, la 26% la grupul de vârstă 51-60 ani, după care creşte la 51,9% la pacienții în vârstă de peste 61 de ani. Şi alti autori (12) menționează că, sub vârsta de 30 ani, incidența CG are valori scăzute pentru ca după să crească rapid şi continuu, cea mai mare frecvență fiind semnalată la pacienții vârstnici.

Şi în studiul nostru, cele mai frecvente cazuri (52%) s-au înregistrat la persoane în vârstă de peste 61 ani, iar vârsta medie a pacienților a fost de 60,32±11,87. Mitrut şi Genunche (13), la cei 415 pacienți diagnosticați cu CG, au evaluat vârsta medie la 48±7 ani.

Incidența cazurilor noi de CG asistate în Spitalul Municipal de Urgență Moineşti în relație cu mediul de proveniență a fost exprimată printr-un raport dintre rural şi urban de 1,5/1, rezultând că numărul de pacienți cu această afecțiune provin din mediul rural mai mult decât cei din urban (59,7% / 40,2%).

Popescu şi Pascu (14) au obținut rezultate diferite într-un studiu efectuat pe 257 de cazuri cu CG, semnalând diferențe minime între statusul socio-economic şi mediul de proveniență urban–rural.

În studiul noastru, la 12 (15,59%) bolnavi s-a observat prezența în antecedentele eredocolaterale a cancerului cu diverse localizări, ceea ce pune în discuție rolul amprentei genetice în determinarea neoplaziilor.

Analiza distribuției cazurilor noi de CG în relație cu antecedentele personale patologice a arătat că 15 (19,5%) pacienți au avut ulcer gastric/duodenal.

Studiul privind incidența CG pentru acelaşi lot evaluat în relație cu condițiile de viață a evidențiat că 52% au consumat diferite toxice, îndeosebi tutun (49,35%) şi alcool (35,06%).

CONCLUZII

Deşi valorile incidenței CG au scăzut simțitor în unele tări, ca de exemplu SUA (7,5/100000), acestea continuă să rămână ridicate în altele, cum este cazul Japoniei (95,5/100000) şi al României (21,15/100000), reprezentând o parte semnificativă din valorile mortalității prin cancer.

În studiul efectuat de noi am constatat

preponderența CG la sexul masculin față de feminin (raport: 2,34/1).

Cele mai multe cazuri au fost înregistrate la persoanele de peste 61 ani cu 40 (52,4%) cazuri, față de numai 2 (2,6%) la grupurile de vârstă sub 30 ani.

Etiologia bolii considerată plurifactorială, în 12 (15,6%) cazuri boala canceroasă a fost prezentă în familie, sugerându-se implicarea şi a factorului genetic.

Într-un număr de 15 (19,5%) cazuri din lotul studiat în antecedentele patologice s-a semnalat ulcerul gastric/duodenal.

Frecvența ridicată a consumatorilor de tutun şi/sau alcool, a sugerat posibilitatea implicării în etiologia CG.

CALITATEA VIEȚII LA PACIENȚII CENTRULUI REGIONAL HIV/SIDA DIN IAŞI

Carmen Manciuc[1], Alexandra Largu[2], A. Vâță[1], Cristina Nicolau[2], L. Prisacaru[2], Daniela Stoica[2], Carmen Dorobăț[1]

Universitatea de Medicină şi Farmacie „Gr. T. Popa" Iaşi

Facultatea de Medicină

1. Disciplina de Boli Infecțioase

2. Spitalul Clinic de Boli Infecțioase „Sf. Parascheva" Iaşi

THE QUALITY OF LIFE IF HIV/AIDS PATIENTS IN THE REGIONAL CENTER FROM IAŞI (Abstract): Quality of life in relation to health is a consequence of disease and treatment on the patient's perception of his ability to have a full and useful life. Due to its nature, the quality of life is a multidimensional and subjective construct, based on the patient's experience. We operationalized the quality of life using the following parameters: CD4 count and HIV viral levels in the patient's blood, the number of days of hospitalization, number of antiretroviral plans, types of side effects and their frequency, psychological issues (anxiety, depression, and neurotic tendencies). Methods: We centralized data from a total of 600 patients from the Regional Center in Iaşi in 2010-2011. Side effects accused by the patients emerged from discussions with the infectious disease doctor and psychologist, and psychological aspects were measured by specific instruments (PA Inventory, Beck Depression Scale). **Results**: Most patients enrolled in the study were male (59%) with mean age of 21.1 years. 34% of them came from rural areas. Average schooling level was 6 primary classes, with extremes between the two classes of primary and higher education. Only 14% of patients had a job, while the rest did not have a stable job or were not employed. 38% came from broken homes or foster care. 85% of patients were in therapy at the time of data centralization. 55% were in the second, third or fourth regimen. 25% were at their first scheme, while 10% in the seventh - eighth scheme. The mean CD4 count ranged between 13 and 269/mmc, while the average viral load varied between 1730 and 3.180.000/mmc. The average number of days of hospitalization was 4. Among the antiretroviral side effects patients complained nausea and vomiting in 85% of cases, lipodystrophy symptoms in 25% of cases, diarrhea 15%. With regard to psychological aspects, 65% of patients showed an above average level of anxiety, 40% showed depressive symptoms, while 10% had specific obsessions-compulsions, and 10% neurotic and hysterical tendencies. **Conclusions**: By measuring the quality of life through the above parameters, we obtained a clear and comprehensive picture of the situation facing the HIV patient. We believe that close cooperation between the team of doctors and psychologists assisting the infectious patient, on the one hand, and specialists in other medical fields that interact with the patient, on the other hand, can enhance the quality of life of the HIV patient and maintain it at a comfortable level.
Key words: QUALITY OF LIFE, HIV/AIDS, SIDE EFFECTS, ARV THERAPY.

Calitatea vieții, în raportul sănătate/boală

Calitatea vieții se referă în esență la "caracterul mai mult sau mai puțin "bun" sau de "satisfăcător" al vieții oamenilor. Este un concept complex, cu multiple laturi

şi posibilități de abordare. Deşi este folosit frecvent în viața de zi cu zi, nu întruneşte o definiție unanimă a specialiştilor.

Calitatea vieții din punct de vedere obiectiv se referă "standardul individual de viață reprezentat de condițiile verificabile caracteristice unei unități culturale" (Evans 1994). Din punct de vedere subiectiv, aceasta e definită ca "gradul în care viața individuală este percepută ca îndeplinind unele standarde interne, explicite sau implicite" (Evans 1994). Însă distincția calitate subiectivă/calitate obiectivă ridică numeroase controverse.

O stare bună de sănătate este un element esențial al bunăstării umane reprezentând o valoare în sine. La nivel individual, o stare bună de sănătate reprezintă o componentă importantă a capitalului uman, permițând oamenilor să îşi desfăşoare activitățile, să îşi îndeplinească țelurile, să aibă o viață completă şi să fie membri activi ai societății. La nivel societal, o stare de sănătate ridicată este un element-cheie al capitalului uman al fiecărei țări, contribuind la competitivitatea ei față de alte țări.

În cercetările de calitatea vieții putem considera ca sănătatea este abordată din două perspective distincte. O primă abordare constă în considerarea sănătății ca o dimensiune, ca un domeniu al calității vieții. Dimensiunea sănătății, ca şi celelalte sfere ale vieții umane, sunt descrise prin indicatori subiectivi şi obiectivi, accentul fiind pus pe modul în care oamenii îşi evaluează propria stare de sănătate, accesul la servicii de sănătate, precum şi evaluarea acestora. Indicatorii utilizați pentru a descrie sfera sănătății pot fi atât subiectivi şi cât obiectivi, situați la niveluri diferite de analiză. Evaluarea propriei stări de sănătate, constrângerile percepute impuse de starea de sănătate, satisfacția față de propria sănătate, percepția accesului la servicii de îngrijire a sănătății, speranța de viață la naştere, mortalitatea infantilă, ratele de mortalitate sau morbiditate sau cheltuielile cu serviciile de îngrijire a sănătății ca procent din PIB reprezintă câțiva dintre indicatori folosiți în cercetarea calității vieții. Sursele de date pot fi multiple: cercetări focalizate pe calitatea vieții, cercetări cu teme diverse, care cuprind şi indicatori de calitatea vieții, cercetări specializate pe domeniul sănătății, sisteme de indicatori de calitatea vieții şi surse de date statistice la nivel național sau internațional. Caracteristic acestei abordări este faptul că evidențiază modul în care oamenii îşi evaluează şi resimt condițiile de viață, resursele şi oportunitățile pe care le au în sfera sănătății. Identificarea inegalităților în ceea ce priveşte starea de sănătate sau de acces la serviciile de îngrijire a sănătății constituie informații esențiale în procesul politicilor sociale.

Cea de-a doua abordare este aceea a calității vieții din perspectiva sănătății, reprezentând o bogată direcție de studiu în cercetările de calitatea vieții. Studiile de calitatea vieții în domeniul sănătății resimt pe modul în care pacienții cu diferite probleme de sănătate îşi experimentează calitatea vieții, pe percepțiile oamenilor care descriu diferite stări de sănătate sau pe timpul de supraviețuire al beneficiarilor de tratamente medicale. În această abordare au fost dezvoltați un număr impresionat de indicatori şi indici de calitatea vieții.

În articolul de față vom privi calitatea vieții prin prisma celei de-a doua abordări.

Calitatea vieții în raport cu sănătatea este consecința bolii şi tratamentului asupra percepției pacientului privind capacitatea sa de a avea o viață deplină şi utilă. Prin natura ei, calitatea vieții este un construct multidimensional şi subiectiv, bazându-se pe experiența pacientului.

Infecția HIV şi boala SIDA – aspecte medicale, sociale şi psihologice

Infecția cu virusul imunodeficienței umane (HIV) în stadiul ei cel mai avansat, sindromul de imunodeficiență dobândită (SIDA), se caracterizează clinic printr-un deficit imunitar complex predominant celular, care predispune la diferite suprainfecții: bacteriene, virale, fungice, cu protozoare şi o evoluție invariabil letală în luni sau ani. Virusul HIV determină infecția CD4, prăbuşirea sistemului de apărare imunitar, determină infecția sistemului nervos central, infecții oportuniste şi apariția de tumori.

Agentul cauzal al infecției HIV este reprezentat de retrovirus, care afectează doar celulele cu receptori CD4-LT4, din țesuturi şi neuroni, şi se multiplică în prezența anticorpilor.

Jonathan Mann, fost Director al Programului Global HIV/SIDA al OMS, făcea referire, în 1987, la trei epidemii mondiale majore, legate de virusul HIV.

Prima epidemie se referă la infecția cu HIV, care intră în comunități silențios şi neobservat, întrucât persoana infectată poate să nu fie conştientă de acest lucru pe toata perioada incubației şi chiar a infecției asimptomatice.

A doua este epidemia SIDA, care apare atunci când infecția cu HIV determină apariția unor boli grave – în organism pătrunde un agent patogen căruia sistemul imunitar nu îi poate face față.

A treia componentă este cea a răspunsurilor sociale, culturale, economice şi politice, date primelor două tipuri de epidemii. „Cercetările sociologice şi epidemiologice focalizate asupra fenomenului SIDA pun accentul pe dimensiunile şi implicațiile socioculturale, demografice, economice şi chiar politice ale acestui fenomen complex, care debutează ca problemă medicală, devenind în timp o adevărată şi tulburătoare problemă socială." (Buzducea, 1997) Este legată de discriminare, stigmatizare, blamare, respingere colectivă, ceea ce împiedică o luptă eficientă împotriva primelor două tipuri de epidemii.

Odată ce infecția a fost detectată, pacientul este sfatuit şi informat despre importanța aderenței la tratament. Medicația previne răspândirea HIV în sânge, contribuie la susținerea sistemului imunitar, şi prelungeşte astfel considerabil viața pacientului.

În prezent există mai mult de 20 de medicamente antiretrovirale aprobate în SUA şi Europa (inclusiv farmaceutice combinate) şi multe altele în curs de aprobare. La fel ca majoritatea medicamentelor, antiretroviralele pot provoca reacții adverse. Aceste efecte nedorite sunt adesea uşoare, dar uneori ele sunt mai grave şi pot avea un impact major asupra sănătății sau calității vieții. De asemenea, în cazuri rare, efectele secundare pot pune viața pacientului în pericol (tab. 1)

TABELUL I

Principalele efecte secundare ale terapiei antiretrovirale

Simptom	Medicament folosit
Diaree	În special inhibitori de protează
Greață şi vomă	Aproape toate medicamentele antiretrovirale
Iritații	Nevirapine, abacavir
Lipodistrofie	Combinații de medicamente din clasa NRTI şi inhibitori de protează
Anomalii lipidice care duc la afecțiuni cardiace	Combinații de medicamente din clasa NRTI şi inhibitori de protează

Caracteristica principală a pacienților care trăiesc cu HIV în România este că aceştie sunt parte dintr-o cohortă ce reprezintă aproape 90% din copiii născuți în perioada 1988-1989. Aceşti pacienți au fost diagnosticați cu infecție HIV la vârsta de 3-6 ani şi au trăit cu HIV întreaga lor copilărie şi adolescență, fiind supravegheați şi monitorizați de către familii şi personalul medical din clinicile de boli infecțioase. Prin urmare, aceştia au crescut odată cu dezvoltarea liniilor terapeutice şi cu trecerea de la mono-şi bi-terapie la terapia HAART. Mulți dintre ei au la activ peste 10 regimuri experimentale, inclusiv utilizarea de inhibitori de protează de ultima generatie şi coformulări ale inhibitorilor nucleozidici. O altă caracteristică specifică pentru aceşti pacienți este coinfecția cu hepatita B şi C în peste 12% din cazuri. Componenta delta a virusului hepatitei este de asemenea prezentă, 1% din toți adolescenții infectați HIV/SIDA suferă de o coinfecție cu hepatită B + D + C.

Conştientizarea infectării cu un virus precum HIV determină la aumite structuri de personalitate o accentuare a stresului şi a neliniştii sub forma manifestărilor anxioase, depresive, însoşite de comportamente obsesiv-compulsive specifice percepției pacientului despre boală (spălarea excesivă, neatingerea obiectelor din jur, neatingerea persoanelor din jur, anumite ritualuri de curățenie a casei sau a obiectelor personale). De asemenea, în cazul persoanelor cu tendințe demonstrative sau hipertimice, pot apărea manifestări nevrotice, de la banalele „crize de nervi", cu o frecvență medie sau ridicată, la aspecte isterice şi crize de isterie.

Am operaționalizat calitatea vieții pacienților infectați HIV în următorii parametri: valoarea CD4 şi nivelul viremiei HIV în sânge; numărul de zile de spitalizare; numărul de scheme terapeutice; tipul de efecte secundare acuzate şi frecvența acestora; aspecte psihologice (anxietate, depresie, tendințe nevrotice).

MATERIAL ŞI METODĂ

Am centralizat datele provenind de la un număr de 600 de pacienți aflați în evidența Centrului Regional Iaşi, în perioada 2010-2011.

Efectele secundare acuzate de pacienți au reieşit din discuțiile cu medicul infecționist şi cu psihologul, iar aspectele psihologice au fost măsurate prin instrumente specifice (Inventarul P.A., Scala de depresie Beck).

REZULTATE

Majoritatea pacienților înrolați în studiu au fost de sex masculin (59%), cu vârsta medie de 21,1 ani.

34% dintre aceştia proveneau din mediul rural. Gradul de şcolarizare mediu a fost de 6 clase, cu extreme între 2 clase primare şi studii superioare.

Doar 14% dintre pacienți aveau un loc de muncă, în timp ce restul nu aveau o meserie stabilă şi nu erau angajați; 38% proveneau din familii destrămate sau din asistență maternală.

85% dintre pacienți se aflau în terapie în momentul centralizării datelor. 55% se aflau la a doua, a treia sau a patra schemă terapeutică. 25% se aflau la prima schemă, în timp ce 10% la a şaptea – a opta schemă (fig. 1).

Valoarea medie a CD4 a variat între 13 şi 269 /mm^3, în timp ce încărcătura virală medie a variat între 1730 şi 3.180.000/mm^3.

Numărul mediu de zile de spitalizare a fost de 4,3, cu extreme între 1 şi 16.

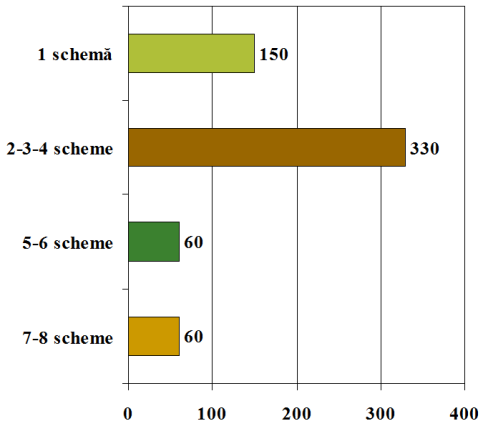

Fig. 1. Numărul de scheme antiretrovirale pentru pacienții monitorizați

Dintre efectele secundare ale antiretroviralelor, pacienții au acuzat greață şi vomă în 85% din cazuri, manifestări lipodistrofice în 25% din cazuri, diaree 15%.

În ceea ce priveşte aspectele psihologice, 65% dintre pacienți au manifestat un nivel pestre medie al anxietății, 40% au evidențiat manifestări depresive, în timp ce 10% au prezentat obsesii-compulsii specifice, şi 10% tendințe nevrotice şi isterice.

CONCLUZII

Operaționalizând calitatea vieții după parametrii prezentați anterior, am obținut o imagine clară şi multilaterală a situației cu care se confruntă pacientul HIV. Considerăm că o colaborare strânsă între echipa de medici infecționişti şi psihologi care asistă pacientul, pe de o parte, şi specialiştii din alte domenii medicale care interacționează cu pacientul, pe de altă parte, poate contribui la creşterea calității vieții pacientului HIV şi la menținerea acesteia la un nivel confortabil.

EXPERIMENTAL RESEARCH REGARDING THE INFLUENCE OF THE STRESS FACTORS IN AN ANIMAL MODEL OF HELLP SYNDROME (Abstract): **Aim**: to study the effects of licht/dark induced-stress in an animal model of HELLP syndrome. **Material and methods**: The experiment was carried out on white female Wistar rats treated intraperitoneally, for 4 weeks, as follows: Group 1: saline solution 0.5ml/100g weight; Group 2: saline solution + dark induced-stress, continuously, 28 days; Group 3: saline solution + light induced-stress, continuously, 28 days; Group 4: endotelin-1; Group 5: endotelin-1 + dark induced-stress, continuously, 28 days; Group 6: endotelin-1 + light induced-stress, continuously, 28 days. Endotelin-1 0.125nmol/kbw was initially administered, followed by 0.25nmol/kbw 30 min later, 2 times/week. **Results**: At the end of the experiment blood pressure was measured and blood samples were taken to assess: leukocyte formula, phagocytic capacity of peripheral neutrophils and serum complement activity, aspartate aminotransferase (ASAT), alanine aminotransferase (ALAT) and lactic dehydrogenase (LDH) activity, total bilirubin and lipid profile. **Conclusions**:In these experimental conditions we obtained an animal model of partial HELLP syndrome (elevated liver enzyme levels and a low platelet count, values emphasized by light induced-stress, without hemolysis). In chronically stressed animals we found the highest levels of blood pressure, a decrease of plasmatic cortisol level and of phagocytic capacity of peripheral neutrophils and an increase of total cholesterol. **Key words**: EXPERIMENTAL HELLP SYNDROME, BLOOD PRESSURE, STRESS

HELLP este termenul medical pentru una dintre cele mai severe complicaţii ale pre-eclampsiei, în care se combină o afectare a funcţiei hepatice cu tulburări de coagulare a sângelui. **H** reprezintă iniţiala cuvântului hemoliză (fenomen ce se produce în cursul sindromului); **EL** provine de la cuvântul „elevated", din limba engleză, ce exprimă creşterea nivelului enzimelor hepatice, în condiţiile afectării funcţiei şi/sau structurii hepatice; **LP** reprezintă abrevierea de la „low level of platelets", ce exprimă nivelul scăzut al trombocitelor sangvine şi, implicit, alterări ale procesului normal de coagulare (1,2,3).

Sindromul HELLP este caracterizat prin următoarele aspecte: hemoliză, creşterea enzimelor hepatice şi scăderea numărului trombocitelor. De asemenea, pot să apară: cefalee, tulburări de vedere şi edem pulmonar acut (4,5). Sindromul HELLP poate să apară în orice stadiu de evoluţie a sarcinii,

mai ales în trimestrul al treilea de sarcină (6).

Scopul acestei cercetări a constat în evaluarea influenţei factorilor de stres pe un model animal de sindrom HELLP indus experimental.

MATERIAL ŞI METODĂ

Au fost utilizate 6 loturi de câte 6 femele de şobolan Wistar (180-200g), proveniţi de la Institutul de Sănătate Publică din Iaşi, trataţi conform schemei: **L1** = SF = Ser fiziologic (0,5ml/100g corp/zi); **L2** = SF+î = Ser fiziologic (0,5ml/100g corp/zi) + stres indus prin menţinerea la întuneric continuu, timp de 28 de zile; **L3** = SF+l = Ser fiziologic (0,5ml/100g corp/zi) + stres indus prin menţinerea la lumină continuă, timp de 28 de zile; **L4** = ET-1 = Endotelină-1 (0,125nmol/kg corp, intraperitoneal (i.p.), iar, după 30 de minute, 0,25nmol/kg corp, i.p., 2 administrări pe săptămână, 4 săptămâni); **L5** = ET-1+î = Endotelină-1 (0,125nmol/kg corp, i.p., iar, după 30 de minute, 0,25nmol/kg corp, i.p., 2 administrări pe săptămână, 4 săptămâni) + stres indus prin menţinerea la întuneric continuu, timp de 28 de zile; **L6** = ET-1+l = Endotelină-1 (0,125nmol/kg corp, i.p., iar, după 30 de minute, 0,25nmol/kg corp, i.p., 2 administrări pe săptămână, 4 săptămâni) + stres indus prin menţinerea la lumină continuă, timp de 28 de zile.

Substanţele au fost administrate conform schemei de mai sus, începând cu ora 8 dimineaţa, timp de 28 zile.

După 28 zile de tratament s-a recoltat sânge din plexul retroorbitar (respectând normele instituţionale şi internaţionale de etică ale experimentului pe animale de laborator) şi au fost determinaţi următorii parametri: tensiunea arterială (utilizând sfigmomanometrul HAMEG), nivelul cortizolului sanguin, formula leucocitară, capacitatea de fagocitoză a PMN din sângele periferic (Testul Nitro Blue Tetrazolium), activitatea complementului seric, valorile transaminazei glutamice oxaloacetice (TGO sau aminotransferaza aspartat, ASAT), transaminazei glutamice piruvice (TGP sau aminotransferaza alanina, ALAT), lactat dehidrogenazei (LDH), bilirubinei serice totale, colesterolului total, LDL-colesterolului şi HDL-colesterolului, trigliceridelor şi glicemiei, precum şi nivelurile globulelor roşii, hemoglobinei, hematocritului, globulelor albe şi trombocitelor. Aceşti parametri au fost determinaţi cu un analizor pentru teste biochimice VITROS 750 XRC, folosind reactivi Johnson& Johnson, respectiv un analizor de hematologie HEMA-VET. Rezultatele au fost apoi prelucrate statistic folosind testul „t-Student”.

REZULTATE ŞI DISCUŢII

Administrarea repetată de endotelină-1 determină creşterea valorilor tensiunii arteriale la femelele de şobolan Wistar. Aceste valori sunt semnificativ statistic crescute în condiţiile expunerii la stres comparativ cu animalele care nu au fost menţinute în aceste condiţii experimentale. Cele mai ridicate valori ale tensiunii arteriale au fost înregistrate la şobolanii Wistar cărora li s-a administrat endotelină-1 şi au fost expuşi la lumină continuă (fig. 1).

În condiţiile experimentale ale stresului cronic realizat, s-a constatat o scădere a valorilor cortizolului plasmatic (fig. 2), comparativ cu lotul martor, acest efect fiind semnificativ statistic mai puternic la animalele cu sindrom HELLP indus experimental şi menţinute în condiţii de lumină continuă.

Nivelurile cortizolului seric cresc în timpul unei sarcini normale la niveluri care sunt de 3 ori mai mari. De asemenea, nu-

meroase date din literatură evidenţiază faptul că, într-o sarcină normală, concomitent cu creşterea cortizolului sanguin se realizează, pe de o parte, o creştere a nivelului ACTH şi a nivelului angiotensinei II, iar, pe de altă parte, o scădere a dehidroepiandrosteronului, a hormonului foliculostimulator şi a hormonului luteinizant (7).

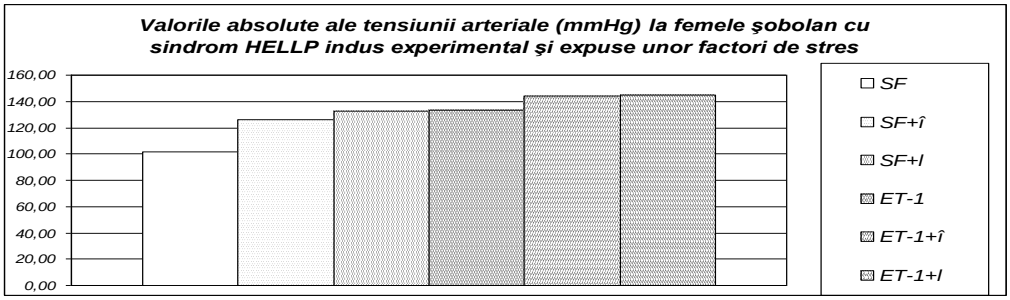

Fig. 1. Valorile absolute ale tensiunii arteriale după 28 de zile

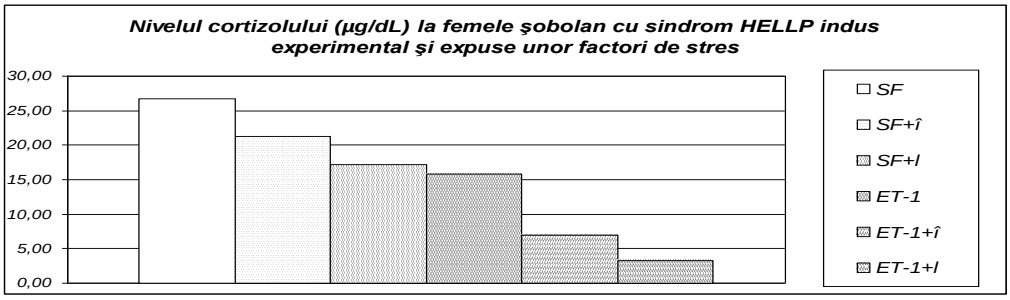

Fig. 2. Nivelurile cortizolului sanguin după 28 de zile

În condiţiile experimentale realizate, nu s-au constatat modificări semnificative statistic ale numărului eritrocitelor, valorilor hemoglobinei sau hematocritului , la nici unul din loturile testate, comparativ cu lotul martor. Nu s-au constatat modificări semnificative statistic ale numărului total de leucocite ale formulei leucocitare, şi nici a activităţii complementului seric.

Pe de altă parte, s-a evidenţiat o scădere semnificativă statistic a capacităţii de fagocitoză a PMN din sângele periferic (testul NBT) la femelele de şobolan cu sindrom HELLP indus experimental şi expuse stresului (fig. 3). Nivelul cel mai scăzut al acestui parametru a fost înregistrat la animalele din lotul expus la lumină continuă.

S-a constatat, însă, o trombocitopenie marcată (fig. 4) faţă de lotul martor, cel mai puternic efect înregistrându-se la femelele de şobolan cu sindrom HELLP indus experimental şi menţinute la lumină continuă, timp de 28 de zile.

În cursul experimentelor, s-a constatat creşterea transaminazelor la toate loturile analizate, comparativ cu lotul martor. Creşterea transaminazelor este efectul alterării permeabilităţii membranei celulare din cauza furtunii steroidiene induse de stres (8). Pe de altă parte, nu s-a constatat hemoliză, ajungând, astfel, la concluzia realizării unui sindrom HELLP parţial. Modelul

experimental realizat pe femele de şobolan reprezintă o alternativă experimentală pentru studiul sindromului HELLP, care a fost realizat pentru prima dată pe femele iepure de către Halim A şi colaboratorii, în 1993 (9). De asemenea, nu s-au înregistrat modificări semnificative statistic ale bilirubinei serice totale comparativ cu lotul martor.

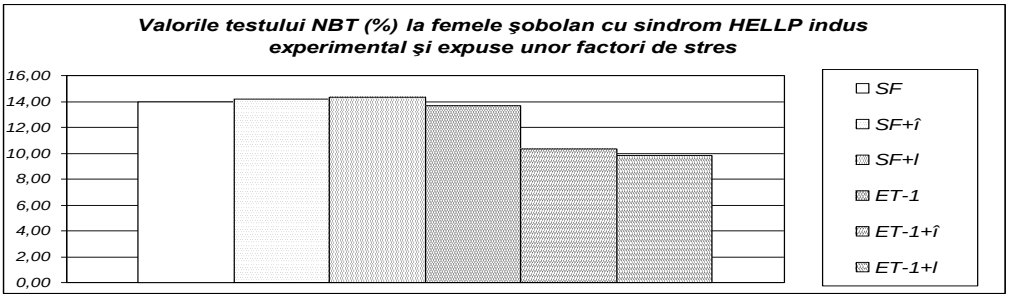

Fig. 3. Valorile testului NBT după 28 de zile

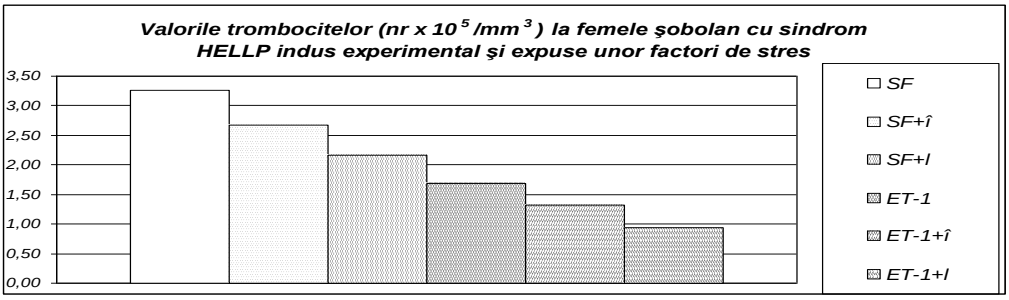

Fig. 4. Valorile trombocitelor după 28 de zile

Datele din literatură sugerează că există o influenţă reciprocă între glucocorticosteroizi şi steroizii sexuali în reglarea funcţiilor imune dependente de timus. De fapt, impactul fondului de hormoni sexuali în răspunsul imun şi activitatea axei hipotalamo-hipofizo-corticosuprarenaliene sunt perfect ilustrate prin prezenţa dimorfismului sexual în cadrul axei şi al răspunsului imun (10). O parte dintre modificările patologice prezente la gravidele diagnosticate cu HTA pot fi explicate prin corelaţiile existente între reacţia organismului la acţiunea unui factor stresor şi „furtuna endocrină şi imunologică" indusă de sarcină. Deşi este o stare fiziologică, sarcina influenţează profund statusul imun matern (11). Imunodepresia corelată cu vârsta gestaţională şi cu factorii de risc materni pentru apariţia HTA poate explica incidenţa mai mare a patologiei hipertensive la primipare.

CONCLUZII

În acest experiment a fost obţinut un sindrom HELLP parţial (creşterea nivelurilor transaminazelor şi trombocitopenie, fără hemoliză), prin administrarea endotelinei-1 conform schemei prezentate, pe fondul unei creşteri semnificative a valorilor tensiunii arteriale la femele şobolan Wistar. Aceste valori sunt semnificativ statistic crescute în condiţiile expunerii la stres, comparativ cu

animalele care nu au fost menţinute în aceste condiţii experimentale. Cele mai ridicate valori ale tensiunii arteriale au fost înregistrate la şobolanii Wistar cărora li s-a administrat endotelină-1 şi au fost expuşi la lumină continuă.

În condiţiile experimentale ale stresului cronic realizat, s-a constatat o scădere a valorilor cortizolului plasmatic şi a capacităţii de fagocitoză a PMN din sângele periferic, comparativ cu lotul martor, acest efect fiind semnificativ statistic mai puternic la animalele cu sindrom HELLP indus experimental şi menţinute în condiţii de lumină continuă.

S-a constatat o trombocitopenie marcată faţă de lotul martor, cel mai puternic efect înregistrându-se la femelele de şobolan cu sindrom HELLP indus experimental şi menţinute la lumină continuă timp de 28 de zile.

În cursul experimentelor, s-a constatat creşterea transaminazelor la toate loturile analizate, comparativ cu lotul martor.

ASSESSMENT OF CONSUMER HEALTH SERVICES IN THE IASI TOWN PUBLIC HEALTH CARE SYSTEM (Abstract). **Aim**: The study was designed to assess patient satisfaction regarding the quality of medical care delivered in 2010, the financial accessibility of the used services, the time span accessibility to the services used, doctor-patient relationship, and quality of health services. **Materials and method**: This study was carried out on a series of 150 randomly selected patients, age-range18 to 70 years. These patients were asked to fill out a 44-item questionnaire including demographic data (age, education, environment - rural or urban area, difficult financial situation) and questions on the quality of the delivered medical care and the performance of the qualified medical staff. **Results and discussion**: The global assessment of the quality of health services shows that it is mainly satisfactory (42.00%) and good (31.33%). The primary health services (family medicine) are mostly regarded as very good (38.00%), good (28.67%) and satisfactory (24.67%). As to the specialized outpatient services, most investigated subjects found them satisfactory (32.67%), good (27.33%), and poor and very poor (8.00%). A percentage of 35.33 of the respondents think that the services provided in hospitals are satisfactory, 18,00% good and 9.33% very good. Drug administration was considered satisfactory by 37.33%, while 22.00%and 12.6% believe it to be good and very good, respectively. **Conclusions**: The regular application of questionnaires to measure patient satisfaction and the setting up of a system for measuring the quality of medical care will improve quality of the health services. **Key words:** PATIENT SATISFACTION, DOCTOR-PATIENT RELATIONSHIP, HEALTH SERVICES QUALITY

România are o lungă tradiție în organizarea sistemului de sănătate. În perioada interbelică a existat un sistem de asigurări de boală bazat pe modelul Bismark. Angajații din întreprinderile industriale, comercianții, funcționarii şi familiile acestora, precum şi liberii profesionişti erau beneficiau de asigurări de boală; totuşi, asiguraţii nu reprezentau la vremea respectivă decât 5% din populație. În anul 1949, a fost aprobată Legea Organizării Sistemului de Sănătate de stat şi a urmat o tranziție progresivă către un sistem de sănătate de tip Semaşko. Acesta se baza pe o largă acoperire a populației cu servicii de sănătate. Principalele caracteristici ale sistemului sanitar din România în timpul acestor următoare patru decenii au fost: planificarea şi finanțarea

centralizată de către stat, administrarea rigidă şi monopolul statului asupra serviciilor de sănătate. De asemenea, de remarcat este şi faptul că profesioniştii din sistemul de sănătate erau salariaţi ai statului. Deşi din 1949 au avut loc multe schimbări, noutăţi semnificative au apărut abia în 1978, când a fost promulgată o lege a sănătăţii. Sistemul de sănătate Semaşko din România anterioară lui 1989 a fost un sistem tipic pentru multe dintre ţările din estul şi centrul Europei. Absenţa concurenţei şi a iniţiativei individuale, calitatea precară a serviciilor de sănătate, subfinanţarea cronică, ineficienţa economică, normele rigide şi echipamentele medicale neadecvate au creat în perioada 1989-1997 presiuni pentru schimbarea sistemului. Între 1990 şi 1995, Guvernul şi Ministerul Sănătăţii au adoptat o serie de decrete şi ordine care, în timp, au adud mai multe schimbări. Astfel, după 1995 a fost posibilă implementarea unui sistem de sănătate standardizat şi reglementat bazat pe modelul imaginat de cancelarul german Otto von Bismark (în 1883). Totuşi, moştenirea lăsată de cei patruzeci de ani de comunism şi funcţionarea actuală a sistemului de sănătate românesc reflectă încă, în bună măsură, problemele cronice ale acestuia, cum ar fi: proporţia relativ scăzută din PIB alocată sănătăţii; alocarea centralizată a resurselor; lipsa reacţiei la nevoile locale; calitatea slabă a serviciilor la primul nivel, trimiterile neadecvate şi accentul pus pe serviciile spitaliceşti unde aparatura medicală şi asigurarea cu medicamente sunt deficitare; şi să nu uităm capacitatea managerială redusă a top-managementului sistemului de sănătate şi insuficienţa numerică a personalului care să aibă competenţe în politici publice de sănătate (3).

Începând cu 1995, legi importante privind sistemul de sănătate din România au schimbat practic întreaga structură de organizare şi au stabilit cadrul pentru tranziţia către un sistem bazat pe asigurări sociale de sănătate, mai descentralizat şi pluralist, cu relaţii contractuale între casele de asigurări de sănătate şi furnizorii de servicii de sănătate (2). Astăzi, în România asigurările sociale de sănătate sunt obligatorii şi funcţionează descentralizat pe baza principiului solidarităţii şi subsidiarităţii în colectarea şi utilizarea fondurilor, precum şi a dreptului alegerii libere de către asiguraţi a medicului, a unităţii sanitare şi a casei de asigurări de sănătate (1).

MATERIAL ŞI METODĂ

În studiu au fost incluşi 150 pacienţi. Lotul selectat aleator a cuprins persoane cu vârste între 18 şi 70 de ani. Aceştia au răspuns unui chestionar cu 44 de itemi. Chestionarul include date demografice (vârstă, studii, religie, mediu social rural/ urban, situaţie financiară) şi întrebări (atât închise, cât şi deschise)– privind calitatea actului medical de care au beneficiat, prestanţa personalului medical calificat şi diferenţa pe care acesta o percepe între unităţile medicale publice şi cele private.

Structura pe grupe de vârstă a lotului studiat arată că procentul cel mai mare (48,50%) l-a reprezentat populaţia adultă cu vârste între 30-49 ani, urmat de cel al populaţiei tinere cu vârste între 18-29 ani (20,60%); la polul opus se situează pacienţii cu vârste de 60 ani şi peste (5,80%). Majoritatea pacienţilor luaţi în studiu au fost de sex feminin (62,00%) şi proveneau din mediul urban (56,90%).

Referitor la instrucţia şcolară, ponderea cea mai mare este deţinută de persoanele cu studii medii (27,20%) şi postliceale (13,9%), apoi persoanele cu studii superioare (11,40% învăţământ superior de

scurtă durată, 11,80% învăţământ superior de lungă durată, 16,10% învăţământ postuniversitar), urmat de persoanele cu studii primare (14,7%). Din totalul persoanelor investigate 32,40% erau pensionari.

REZULTATE

Rezultatele studiului reflectă satisfacţia pacienţilor care au beneficiat de servicii publice de sănătate în 2010.

Evaluarea globală a calităţii serviciilor de sănătate accesate în ultimul an de către pacienţii luaţi în studiu arată că aceasta este satisfăcătoare (42,00%) şi bună (31,33%) (fig. 1).

Tot ca o evaluare globală, s-a căutat să se observe dacă sistemul public răspunde nevoilor de sănătate ale populaţiei. Pacienţii luaţi în studiu au răspuns afirmativ în procent de 77,33%.

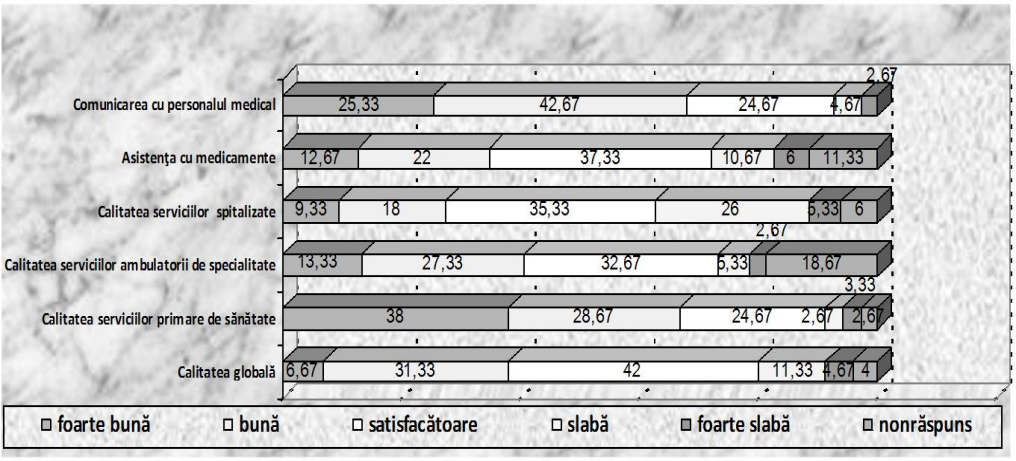

Fig. 1. Calitatea serviciilor de sănătate accesate în ultimul an de către persoanele luate în studiu

Aprecierile referitoare la serviciile primare de sănătate (medicina de familie) sunt foarte bune (38,00%), bune (28,67%) şi satisfăcătoare (24,67%); doar 3,33% din total subiecţilor le-au apreciat ca fiind foarte slabe.

În ceea ce priveşte prestaţiile oferite de ambulatoriul de specialitate, 32,67% dintre subiecţii investigaţi le-au apreciat ca fiind satisfăcătoare şi bune (27,33%), iar 5,33% ca slabe şi 2,67% ca foarte slabe.

Doar 35,33% dintre persoanele luate în studiu au apreciat serviciile secundare de sănătate de care au beneficiat în spitalele publice din Iaşi ca fiind satisfăcătoare şi 18,00% ca bune şi foarte bune. La fel se poate afirma şi despre asistenţa cu medicamente în 2010: 37,33% dintre pacienţi o apreciază ca fiind satisfăcătoare, 22,00% bună şi doar 12,67% ca fiind foarte bună, însă 16,67% o apreciază ca fiind slabă şi foarte slabă.

Referitor la uşurinţa de a obţine îngrijirile medicale de care au nevoie, 53,33% dintre subiecţii investigaţi au răspuns cu "*da, uneori*" şi 30,67% "*da, întotdeauna*". Atunci când pacienţii au avut nevoie de îngrijiri medicale, aceştia le-au apreciat ca fiind adecvate faţă de starea lor de sănătate (59,33%), dar 20,67% au recunoscut că nu au cunoştinţele necesare pentru a evalua obiectiv acest aspect.

În ceea ce priveşte nevoia de a cheltui suplimentar bani din bugetul personal pen-

tru a se trata atunci când sunt bolnavi, majoritatea subiecților (60,67%) apreciază că trebuie să folosească suplimentar bani, 26,00% afirmă că au fost suficiente asigurările de sănătate pentru a fi tratați corespunzător şi 12,67% dintre pacienți nu apelează la bani din buzunarul propriu pentru că nu îşi pot permite.

Referitor la accesibilitatea la îngrijiri de sănătate în localitatea în care domiciliază, cea mai mare parte a pacienților (45,33%) apreciază că pot obține aceste îngrijiri *uneori*, iar 23,33% afirmă că au acces *întotdeauna* la îngrijirile necesare în localitatea de domiciliu. Un procent de 2,00% apreciază că nu au încredere în serviciile de sănătate din localitatea de domiciliu.

Orarul unităților din rețeaua sanitară este apreciat ca fiind corespunzător de către mai mult de jumătate dintre subiecții investigați (50,90%) şi satisfăcător (31,80%), doar 6,60% din subiecți afirmă că acesta nu se respectă.

Aproape în majoritate (93,33%) dintre subiecții luați în studiu consideră că statul trebuie să se implice în sprijinirea asigurărilor sociale de sănătate din România. 32,67% dintre subiecții cuprinşi în cercetare consideră că atunci când au avut nevoie de servicii medicale nu au primit serviciile medicale la nivelul contribuției plătite.

În ceea ce priveşte accesul asiguraților la aceleaşi servicii medicale, indiferent de suma plătită diferit pentru contribuția la fondul asigurărilor sociale de sănătate, un procent foarte mare (62,60%) consideră că acest lucru este corect. Există şi subiecți (16,40%) care apreciază că nu îi interesează acest subiect, pentru ei fiind important să primească servicii de sănătate adecvate nevoilor lor de sănătate atunci când au nevoie.

Pentru cei care nu plătesc contribuții la fondul de asigurările sociale de sănătate este un lucru firesc să primească servicii medicale (48,00%) deoarece consideră că statul este obligat să asigure ocrotirea sănătății cetățenilor în virtutea contribuției plătite de-a lungul activității, chiar dacă în prezent nu contribuie (în cazul pensionarilor, şomerilor etc.). Faptul că anumite categorii de persoane care beneficiază de serviciilor de sănătate nu contribuie financiar la fondul de sănătate este acceptat de 34,67% din totalul subiecților luați în studiu. De asemenea, 16,67% sunt de părere că acest lucru este de acceptat pentru faptul că şi ei pot ajunge în situația de a nu mai plăti contribuția pentru sănătate (prin ieşirea din perioda de şomaj). La polul opus se află 39,33% dintre subiecți care nu acceptă acest lucru, în principal pentru că pentru a beneficia de servicii de sănătate trebuie să se plătească, dar şi pentru că salariații plătitori de contribuții de sănătate nu pot susține financiar întrega populație a țării.

Contribuția plătită de fiecare asigurat care a primit servicii spitaliceşti în 2010 a fost apreciată ca fiind în general echilibrată (20,00%) şi mare în raport cu serviciile medicale de care au beneficiat (18,00%). Unii asigurați (22,67%) apreciază drept mare în raport cu venitul lunar realizat nivelul contribuției virate la fondul de sănătate, în timp ce doar 6,00% consideră că aceasta este mică în raport cu nevoile lor de sănătate.

Referitor la disponibilitatea de a plăti suplimentar (co-plată) pentru unele servicii medicale (cum ar fi serviciile medicale de înaltă performanță, fertilizare *în vitro* sau corecții estetice), mai mult de jumătate dintre subiecți (54,00%) afirmă că sunt de acord cu aceasta, iar dintre cei care nu sunt de acord (12,00%) consideră că statutul de

asigurat ar trebui să le confere accesibilitate pentru aceste categorii de servicii.

Afirmaţia *"Toţi asiguraţii beneficiază de servicii medicale, medicamente, materiale sanitare / dispozitive medicale în mod nediscriminatoriu / necondiţionat / echitabil / egal"* este considerată adevărată sau parţial adevărată de 58,67% dintre subiecţi. Principalele motive pentru care această afirmaţie a fost considerată neadevărată/sau parţial adevărată au fost: discriminarea (pe criterii etnice, stare materială); unii asiguraţi nu au acces la serviciile medicale datorită distanţei, programului de muncă prelungit.

În ceea ce priveşte serviciile medicale preventive, pentru menţinerea unei stări bune de sănătate 40,67% dintre subiecţi consideră că nu sunt informaţi, doar 15,33% apreciază ca suficientă informarea asupra serviciilor medicale preventive. Există şi un număr relativ important (24,00%) dintre pacienţi care nu înţeleg necesitatea prevenţiei. O mare parte dintre pacienţii cuprinşi în cercetarea de faţă (48,00%) afirmă că au beneficiat de control periodic, ştiind că au acest drept. Dintre cei care nu au beneficiat de acest serviciu, 27,33% au considerat că nu au avut nevoie, în timp ce 22,00% afirmă că nu au ştiut ca au acest drept.

Circuitul bolnavului în sistemul de sănătate nu este cunoscut de 21,33% dintre subiecţi, 12,67% dintre cei care afirmă că îl cunosc, îl desemnează ca fiind următorul: medic de familie-ambulatoriu de specialitate–spital–medic de familie. Aproape toţi subiecţii investigaţi sunt pe lista unui medic de familie (97,33%); dintre aceştia, 26,00% sunt în evidenţă cu boli cronice şi 25,33% sunt în evidenţa unui medic specialist. Majoritatea (77,33%) pacienţilor afirmă că nu au schimbat până acum medicul de familie, dar 10,67% l-au schimbat din următoarele motive: schimbarea domiciliului, distanţa mare faţă de domiciliu, nemulţumirea din cauza timpului mare de aşteptare la cabinet.

Referitor la serviciile primare de sănătate de care au beneficiat, o mare parte au beneficiat de consultaţii şi tratament din partea medicului de familie (39,33%) şi de recomandarea unor investigaţii (16,67%).

Relaţia cu personalul medical este apreciată de majoritatea pacienţilor drept bună (42,67%) şi foarte bună (25,33%); numai 24,67% afirmă că aceasta este satisfăcătoare.

Funcţiile şi rolul Casei Naţionale de Asigurări de Sănătate sunt cunoscute de o parte dintre subiecţi (32,67%). Dintre cei care nu le cunosc, cei mai mulţi (20,67%) susţin că nu au cunoştinţă de existenţa unor campaniilor de informare organizate de această instituţie. Un procent îngrijorător de subiecţi investigaţi (65,33%) afirmă că nu au fost informaţi niciodată de CASJ cu privire la serviciile de sănătate, sau cu privind drepturile şi obligaţiile de asigurat. În ceea ce priveşte informarea de către CAS asupra condiţiilor de furnizare de servicii medicale şi despre schimbările în modul de funcţionare/acordare a acestora, înainte de aplicarea acestor modificări, mai mult de jumătate dintre subiecţi (57,33%) afirmă că aceasta nu a fost făcută corespunzător în 2010.

Atunci când vor să-şi exprime părerea cu privire la serviciile de sănătate primite, majoritatea subiecţilor (41,33%) afirmă că se adresează medicului de familie, urmează apoi casele de asigurări de sănătate, care au fost accesate în acest scop de 23,33% dintre pacienţi, iar la polul opus se află birourile de presă ale caselor de asigurări de sănătate (7,33%).

În ceea ce priveşte necesitatea de a fi

efectuate controale din partea CNAS/ CASSJ la furnizorii de servicii medicale, cu privire la execuţia contractelor şi îndeplinirea obligaţiilor faţă de pacienţii asiguraţi, mai mult de jumătate dintre cei chestionaţi (55,33%) cred în utilitatea acestora pentru o mai bună disciplină financiară în condiţii de criză.

Pentru creşterea performanţei şi calităţii serviciilor de sănătate, 24,00% dintre subiecţi afirmă că este nevoie de îmbunătţirea legislaţiei specifice.

DISCUŢII

Rezultate studiului sunt utile decidenţilor pentru fundamentarea unei strategii de îmbunătăţire a serviciilor de sănătate. Vom prezenta principalele obiective ale acesteia.

În primul rând creşterea calităţii, performanţei, eficienţei şi eficacităţii serviciilor spitaliceşti. Extinderea gamei de îngrijiri de sănătate furnizate de serviciile spitaliceşti cum ar fi: îngrijiri ambulatorii integrate cu cele spitaliceşti, spitalizare de zi, spitalizare de o zi. Populaţia va avea un acces local îmbunătăţit la o gamă mai largă de servicii integrate de asistenţă primară şi spitalicească, mai bine adaptate nevoilor de sănătate ale comunităţii.

Finanţarea echitabilă şi transparentă a serviciilor de sănătate va trebui să se bazeze pe responsabilitatea locală şi pe mecanisme de raportare corespunzătoare. Finanţarea adecvată şi sustenabilă a spitalelor, în concordanţă cu politicile de sănătate şi cu planificarea naţională pe termen lung a numărului de paturi de spital.

Restructurarea unităţilor sanitare în vederea furnizării serviciilor medicale adecvate se va realiza funcţie de nevoile de sănătate ale populaţiei. Închiderea/sau restructurarea unităţilor spitaliceşti subutilizate sau care nu sunt necesare, în vederea limitării pierderilor financiare şi utilizarea resurselor economisite pentru rezolvarea problemelor prioritare de sănătate.

Transferul îngrijirilor furnizate în spitale pentru cazurile sociale şi pentru vârstnicii cu boli cronice către unităţi/organizaţii locale şi/sau către unităţi private, astfel încât spitalele să se poată concentra pe îngrijirile de tip acut.

Dezvoltarea serviciilor de asistenţă primară, în special a îngrijirilor la domiciliu, crearea unor centre de sănătate multifuncţionale atât în mediul urban, cât şi în rural şi integrarea asistenţei primare cu serviciile ambulatorii de specialitate şi serviciile spitaliceşti, în concordanţă şi cu programele naţionale de sănătate.

Îmbunătăţirea managementului operaţional la nivel local, judeţean şi regional.

Revizuirea cadrului legislativ specific pentru a reformare sistemul de sănătate, descentralizarea ulterioară a managementului operaţional şi financiar şi găsirea celor mai bune soluţii pentru satisfacerea nevoilor locale, inclusiv pentru populaţia defavorizată sau vulnerabilă.

Implementarea unui sistem modern de acreditare a serviciilor de sănătate şi a unor sisteme adecvate de monitorizare a managementului calităţii.

Sistemul de sănătate trebuie să furnizeze exclusiv îngrijiri de sănătate şi să coopereze cu sectorul de asistenţă socială pentru creşterea solidarităţii sociale şi a calităţii vieţii.

CONCLUZII

Unităţile din sistemul public de sănătate vor trebui să îmbunătăţească calitatea actului medical, aceasta nu doar din pricina necesităţii de a se alinia cerinţelor europene, ci şi dintr-un alt considerent, mult mai puternic: legea concurenţei.

Aplicarea regulată a chestionarelor care să evalueze satisfacţia pacienţilor precum şi implementarea unui sistem coerent de monitorizare a calităţii creează premisele îmbunătăţirii calităţii serviciilor de sănătate oferite de instituţiile publice.

ASPECTE CLINICE ŞI TERAPEUTICE ALE CARIEI TIMPURII ŞI ALE CARIEI SEVERE TIMPURII – SERIE DE CAZURI

Dana Maxim[1], I. Danilă[2], Carina Balcoş[2]
Universitatea de Medicină şi Farmacie "Gr.T. Popa" Iaşi
Facultatea de Medicină Dentară
1. Disciplina de Pedodonţie
2. Disciplina de Prevenţie Oro-Dentară

CLINICAL AND THERAPEUTICAL ASPECTS OF EARLY CHILDHOOD CARIES AND SEVERE EARLY CHILDHOOD CARIES-CLINICAL CASES (Abstract): ECC(early childhood caries) and SECC(severe early childhood caries), as a particularization of the dental caries during the early childhood (0-3 years) and the middle childhood (3-6 years), generate important oro-dental problems, with long term impact, psycho-somatic, psycho-aesthetic, and social-behaviour, in little children as in adults. **Material and methods:** 35 subjects(20 girls and 15 boys), were evaluated, aged between 3-6 years old, diagnosticated with ECC and SECC.The children were evaluated clinical, paraclinical and psycho-sociological in the Clinic of Paediatric Dentistry, Iasi, Romania. **Results**: In this article, we present 3 clinical cases that show the implication of the socio-emotional factors that produce the early childhood caries, pacient C.L., 6 years old, pacient C.F., 5, 6 years old, and pacient A.D., 6 years old. **Conclusion:** in this study we have evaluated a heterogen structure with major impact on caries risk, clinical variability of the carioactivity in decidual dentition.It is known that more than 64% non-cavitary lesions that appear in a 2 year-old child develop to cavitary lesions in less than a year. **Key words:** EARLY CHILDHOOD CARIES, SEVERE EARLY CHILDHOOD CARIES, PAEDIATRIC DENTISTRY, EARLY CHILDHOOD, SPACE MAINTAINER

Caria timpurie (ECC) şi caria severă timpurie (SECC), ca particularizări ale cariei dentare în perioada copilariei mici (0-3 ani) şi mijlocii (3-6 ani), generează profunde probleme oro-dentare, cu impact pe termen mediu şi lung psiho-somatic, psiho-estetic şi socio-comportamental atât la copii mici cat şi la populatia adultă (1,2).

După cum mentionează Sven Poulsen în 2002 (3), Dănilă I. şi Evghenikos în 2007 (4), aceste entităţi clinice reprezintă o autentică problemă de sanatate publică oro-dentară, prin debutul extrem de timpuriu şi prin riscul înalt de progresie carială, cu rezonanţă directă asupra dentiţiei permanente.

Prin complexitatea sa contextuală şi larga sa variabilitate, ECC şi SECC predicţionează dinamica şi trendul de creştere şi dezvoltare în perioadele dentiţiei mixte şi a dentiţiei permanente tinere (5), cu implicaţii asupra homeostaziei sistemului stomatognat la etapa de adult tânar.

Pe de altă parte experienţele algogene ale copilului preşcolar şi anteprescolar generate de complicaţiile periodontale ale ECC şi SECC, asociate cu tehnici de management pedodontic neadecvate şi o credibilitate discutabilă din partea practicianului faţă de durerea stomatologică a copilului, se prefigurează într-un predictor al fricii, anxietăţii şi fobiei dentare, al demodulării comportamentale pe termen lung a copilului versus cabinet şi tratament stomatologic (6, 7).

Fig. 1. Aspectul extraoral (pacienta1)

Fig. 3. Aspectul extraoral (pacienta2)

Scopul acestui studiu a fost de evaluare a factorilor predictivi în evoluţia stării de sănătate oro-dentară la copii şi optimizarea efectivă a managementului comportamental şi terapeutic preventiv şi curative al afecţiunilor oro-dentare la copilul antepreşcolar şi preşcolar.

Cei 35 de subiecţi implicaţi în studiu (20 fete şi 15 băieţi) cu vârstă cuprinsă între 3 şi 6 ani, provin dintre pacienţii care au solicitat asistentă la Policlinica de Stomatologie Infantilă. Aceştia au fost investigaţi clinic, paraclinic şi psihosociologic. Programul şi studiul au fost precedate de obţinerea consimţământului informat de către apartinator sau educator.

În lucrarea de faţă prezentăm trei cazuri clinice care pun în evidenţă prezenţa factorilor socio-emoţionali care favorizează apariţia cariei severe timpurii.

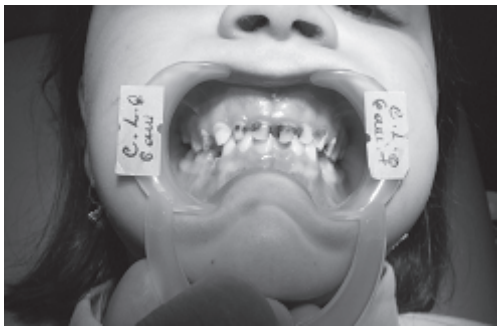

Fig. 2. Aspectul intraoral (pacienta 1)

CAZURI CLINICE

1. Pacienta C.L. în varstă de 6 ani provine dintr-un mediu familial biparental, climat armonios, copil unic, tipar emoţional carenţial, predominant extrovertit. Alimentaţia copilului a fost artificială între 2, 2-10 luni, actualmente preferând alimentele moi. Igiena oro-dentară este inconsecventă şi superficiala. Respiraţie mixtă, tipar constituţional normosom, tipar cranio-cefalic : brahi-cefal, tipar facial : leptoprosop (fig.1).

Diagnostic : carii severe timpurii, fronto--lateral maxilar şi latero-lateral mandibular, complicate la nivelul zonelor de sprijin, cu angrenaje inverse frontale, parcelare în zig--zag (fig.2).

Prognostic bun cu tratament laborios constand in tratamrntul leziunilor carioase si obturatii cu glassionomer pentru leziunile localizate la nivel frontal si latero-lateral sau coroane pedodontice pentru zona laterala.

2. Pacienta C.F. de 5,6 ani provine dintr-un cuplu biparental, cu nivel socio-economic mediu. Temperamental-comportamentul copilul prezintă tendinţe la extrovertenţă, psiho--emoţional fiind netemător, tipar comunicativ, cooperant. Copilul a fost alimentat artificial (biberon) de la vârstă de 6 luni până la 18 luni, asociativ cu suzetă înmuiată în îndulcitori(zahăr, miere de albine). Igiena oro-dentară nesatisfăcătoare, periajul dentar de seară fiind realizat sporadic. Copilul prezintă preferinţe alimentare pentru produse

Fig. 4-5. Aspecte intraorale (pacienta 2)

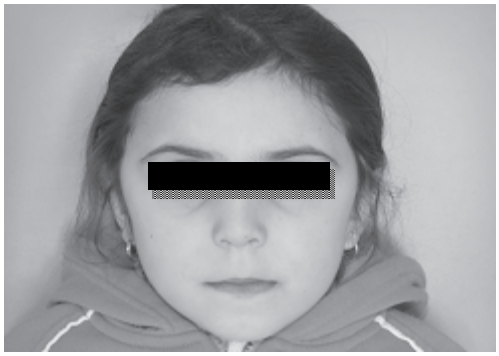

Fig. 6. Aspecte extraorale (pacienta 3)

Fig. 7. Aspecte intraorale (pacienta 3)

Fig. 8. Aspecte intraorale (pacienta 3)

făinoase şi dulciuri. La examenul extraoral se observă tiparul somatic-normosom, tipar cranio-cefalic-brahicefal, tipar facial-euriprosop, respiraţie mixtă iar intraoral deglutiţia infantilă, tendinţa la angrenaje inverse parcelare : 51, 61, 62/82, 81, 71, 72, 73, planul postlacteal în treaptă uşor mezializată (fig.3).

Diagnostic : malocluzie clasa I-Angle, sindrom de suzetă Mugnier, asociat cariei de biberon, carii la nivel incisiv maxilar simple şi complicate periodontal(52) şi la nivel maxilar bilateral, mandibular, simple şi complicate pulpar(84, 85), cu tulburări funcţionale (fig. 4, 5).

Prognostic este bun în condiţia instituirii managementului terapeutic adecvat : educaţional prin instituirea unui comportament sanogen adecvat, ortodontic interceptiv sau curativ prin decondiţionarea deglutiţiei atipice, efectuarea saltului articular la nivelul tiparelor dentare aflate în angrenaj invers incipient si tratamentul leyiunilor carioase simple si complicate.

3. AD.- 6 ani. Subiectul provine dintr-un climat biparental armonios, agreabil, nivel socio-economic mediu, copil unic. Alimentaţia a fost artificială (biberon) între 6 luni-3 ani, deprinderi şi obisnuinţe de igienă oro-dentară inconsecvente şi superficiale, preferinţă pentru alimentele moi, deglutiţie infantilă cu interpoziţie, respiraţie mixtă, emoţional-copilul este nesigur, temperamental şi cu tendinţă la introvertenţă. Tipar somatic- nor-

mosom, tipar cranio-cefalic- dolicoprosop, tipar facial- leptoprosop, sindrom protruziv anterior complet(fig.6).

Diagnostic- malocluzie clasa a III-Angle, ocluzie inversă, inocluzie verticală frontală disfuncţională şi scheletală, carii severe timpurii simple şi complicate cu pierderi premature odontale la nivel frontal maxilar (fig. 7 şi 8).

Prognostic este rezervat necesitand instituirea unui comportament sanogen adecvat, o unui tratament ortodontic interceptiv si curativ prin decondiţionarea deglutiţiei atipice, tratamentul leziunilor carioase simple si complicate cu glasionomer şi menţinatoare de spaţiu pentru pierderile odontale premature.

CONCLUZII

Sub aspectul apartenenţei socio-familiale economice şi ecologice am suprins o structură heterogenă, a lotului de studiu, cu impact major dar diferenţiat asupra riscului carios, al progresiei cariale şi a variabilităţii clinice a carioactivităţii dentare temporare. Trendul rapid ascendent devine tot mai pregnant în raport cu etapa de vârstă a copilului (3-6 ani), la nivel socio-economic scăzut sau nivel educaţional precar al aparţinătorului, carioactivitatea crescută a mamei, in cazul părinţilor foarte ocupaţi, copii crescuţi de rude. Se cunoaşte că peste 64% dintre leziunile necavitare la vârsta de 2 ani, progresează către cavităţi într-un an, aspect susţinut de clasificarea Mejare 199 (3).

TRATAMENTUL ORTODONTIC PREPROTETIC – UN MODEL DE INTERDISCIPLINARITATE ÎN MEDICINA DENTARĂ

Oana Alexandra Eftene[1], Dana Catrinel Ispas[2], Anca Nicoleta Temelcea[1], R.P. Stanciu[1], Ileana Graţiela Simion[1], D. Stanciu[1]
Universitatea de Medicină şi Farmacie "C. Davila" Bucureşti
Facultatea de Medicină Dentară
1. Clinica de Ortodonţie şi Ortopedie Dento-facială
2. Clinica de Implantologie Orală

PREPROSTHETIC ORTHODONTIC TREATMENT (Abstract): If, not long time ago, the simple prosthetic rehabilitation of an edentulous patient – with or without additional maxillary teeth abnormalities – was the only therapeutic solution, presently, the pre-prosthetic orthodontic treatment enabling the dental restoration treatment meets the basic requirements of any dental treatment, i.e. the (re)set-up of the morphological and functional integrity and the functions of jaws, with minimum biological sacrifice. **Key words**: MAXILLARY TEETH ABNORMALITY, PRE-PROSTHETIC ORTHODONTIC TREATMENT

Tratamentul ortodontic preprotetic a intrat în arsenalul terapeutic al medicului dentist din necesitatea de a răspunde cerinţelor tot mai elevate ale pacientului, din ce în ce mai informat, care se prezintă în clinică pentru tratament de specialitate.

Argumentele care vin în sprijinul acestui tip de tratament sunt de natură:

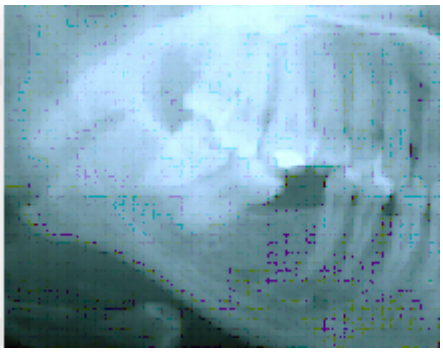

Fig. 1. Solicitarea nefiziologică a molarului doi inferior a determinat transformarea pungii parodontale false într-o pungă parodontală adevărată, care ar fi putut periclita, în lipsa unei intervenţii energice, poziţia dintelui pe arcadă (colecţia Prof. Dr. Dragoş Stanciu)

Biomecanică: odată modificată poziţia corectă de implantare a dinţilor, forţele masticatorii nu mai pot acţiona în axul lung al acestora, ceea ce determină apariţia de forţe parazite, care produc, mai lent sau mai accelerat, afectarea parodonţiului de susţinere (fig. 1), cu efecte pe termen lung asupra „persistenţei" dintelui pe arcadă;

Biologică: există situaţii, şi nu puţine, când printr-un tratament ortodontic bine condus, şi în situaţia când diagnosticul a fost pus corect (ceea ce a dus la selecţia riguroasă a cazului!), spaţiul edentat se închide complet sau aproape complet, fără a mai fi necesară protezarea ulterioară (fig. 2 a şi b);

Estetică: protezarea, de exemplu a pacienţilor cu anomalii de Clasa a II-a, diviziunea 2, fără redresarea prealabilă măcar a poziţiei patognomonice a incisivilor laterali, nu poate oferi rezultate satisfăcătoare din punct de vedere estetic nici pentru cei mai „nepretenţioşi" pacienţi (fig. 3);

Profilactică: dispozitivele ortodontice permit refacerea punctelor de contact inter-

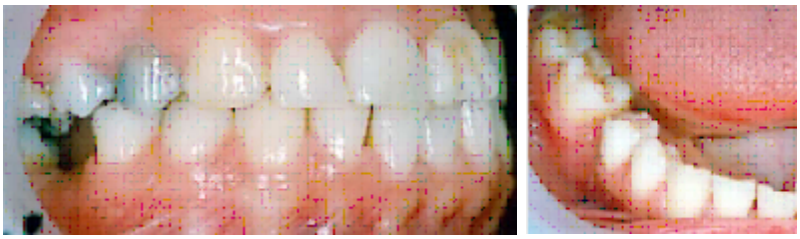

Fig. 2. Edentaţia molarului de şase ani (a) a fost rezolvată prin mijloace ortodontice, care au determinat închiderea aproape completă a breşei (b) (colecţia Prof. Dr. Dragoş Stanciu, Dr. Ileana Simion)

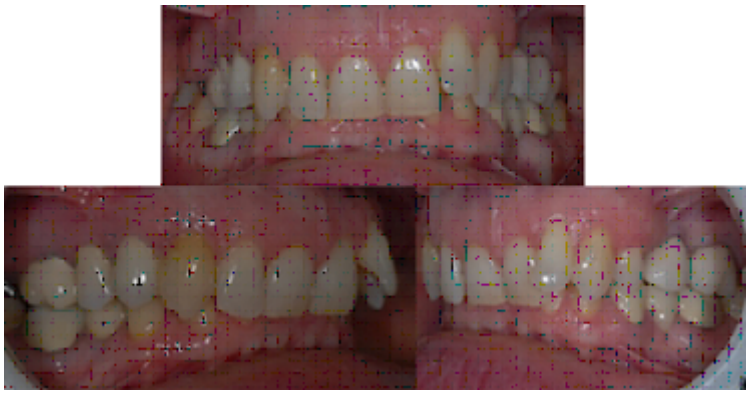

Fig. 3. Rezolvarea protetică a edentaţiilor acestei paciente care prezintă o anomalie de Clasa a II-a, diviziunea 2, înainte de rezolvarea ortodontică a anomaliei de bază s-a soldat cu rezulatate estetice cel puţin necorespunzătoare, care agravează deficitul fizionomic iniţial al malocluziei (colecţia Prof. Dr. Dragoş Stanciu)

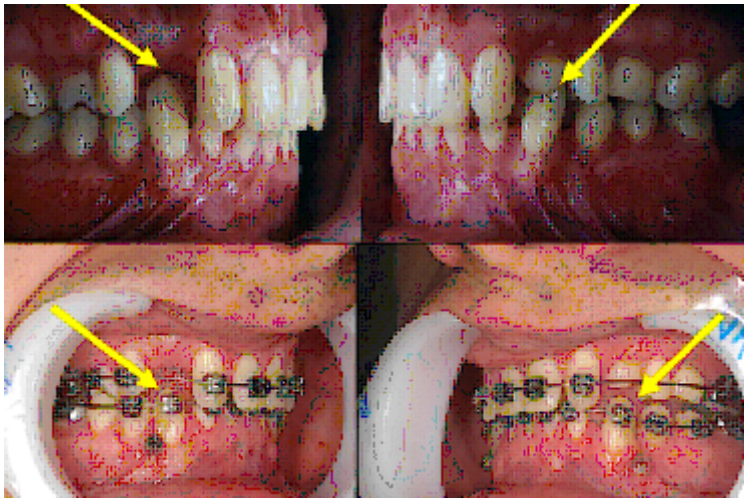

Fig. 4. Redresarea ortodontică a caninilor inferiori a permis protezarea corespunzătoare a zonelor edentate de la maxilar (colecţia Prof. Dr. Dragoş Stanciu, Dr. Ileana Simion)

dentare, cu implicaţii asupra stării de sănătate parodontală ;

Ocluzală : stabilirea / restabilirea unui ghidaj normal, graţie unui tratament ortodontic corespunzător, asigură garanţia unor rezultate protetice foarte bune pe termen lung ; mai mult decât atât, în situaţia unei ocluzii „prăbuşite", tratamentul ortodontic

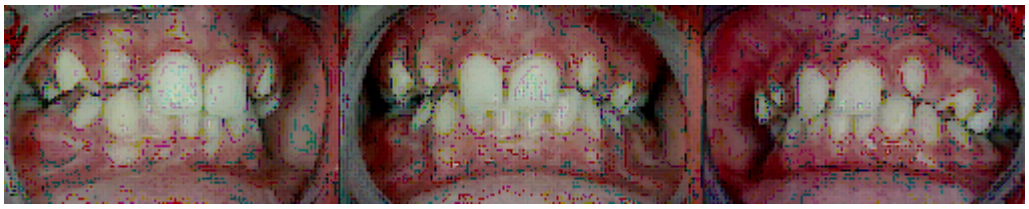

Fig. 5. Aparatul ortodontic va permite, la această pacientă cu anodonţie de incisivi laterali, alunecarea cât mai distal a breşelor edentate, evitându-se astfel protezarea zonelor frontale, cu toate inconvenientele acesteia (colecţia Prof. Dr. Dragoş Stanciu)

este singurul care poate asigura spaţiul necesar inserţiei lucrărilor protetice, în plan vertical – fără modificarea dimensiunii verticale de ocluzie dincolo de limitele fiziologice ale ATM (fig. 4).

Obiectivele tratamentului ortodontic preprotetic, schematic, sunt reprezentate de :

- repoziţionarea dinţilor stâlpi şi paralelizarea acestora ;
- distribuţia mai bună a dinţilor pe arcade, cu mărirea sau micşorarea breşelor edentate în vederea unei eventuale restaurări protetice ulterioare (fig. 5) ;
- repoziţionare radiculară corespunzătoare.

Tehnicile de tratament ortodontic preprotetic folosesc în majoritatea cazurilor aparatură fixă poliagregată, bazată pe conceptul Edgewise Standard Tweed Merrifield.

Etapele de tratament au fiecare obiective distincte, iar aceste obiective sunt aliniate scopului final al tratamentului, fie că este vorba de închiderea completă a spaţiului, şi atunci nu mai este nevoie de protezare ulterioară, fie că este vorba de redistribuirea spaţiului, în vederea unei refaceri protetice cu minim de sacrificiu biologic.

Aparatele şi forţele extraorale sunt utilizate mai ales pentru suplimentarea ancorajului, atunci când mijloacele de tip intraoral nu sunt suficiente pentru a asigura deplasările dentare dorite, pe de o parte, iar pe de altă parte, acestea pot exercita şi acţiuni ortodontice precum corectarea poziţiei molarilor primi superiori, ingresiunea sau egresiunea molarilor, distalizări dentare, modificarea planului de ocluzie, etc.

La sfârşitul tratamentului activ se instituie contenţia, care reprezintă un amalgam de tehnici şi mijloace gândite pentru a stabiliza rezultatele obţinute.

După perioada de contenţie pacientul este redirecţionat către un serviciu de protetică dentară, pentru a se institui, cât mai curând, un tratament de specialitate.

Ca o concluzie putem afirma că principalele avantaje ale tratamentului ortodontic preprotetic sunt reprezentate de posibilităţile pe care acesta le oferă de a restabili funcţionalitatea aparatului dento-maxilar cu minim de sacrificiu biologic, iar principalul dezavantaj – timpul destul de lung de tratament – poate fi uşor contracarat de fundamentele solide pe care tratamentul ortodontic le oferă ca bază de plecare proteticianului.

3. Institutul de Virusologie "Şt.S. Nicolau" Bucureşti

EVALUATION OF P16^{INK4A} AND Ki-67 PROTEINS EXPRESSION IN CERVICAL INTRAEPITHELIAL NEOPLASIA AND THEIR CORRELATION WITH HPV-HR INFECTION (Abstract): **Objective**: The aim of our study was to evaluate the expression of p16^{INK4A} and Ki-67 in cervical intraepithelial neoplasia (CIN) and to correlate the high-risk human papillomavirus (HPV) infection with these two biomarkers. **Material and method**: Sixty patients were included in our study. All of the patient underwent colposcopy-guided biopsy to asses the grade of CIN. For the immunohistochemistry exam we used p16^{INK4A} and Ki-67 antibody and their expression was semiquantitatively classified in 4 classes: 0, 1, 2 and 3. HPV genotyping was used to detect high-risk HPV. **Results**: 7 of our cases were benign (11.66%); 18 cases presented CIN1 (30%), 14 cases CIN2 (23.33%), 16 cases CIN3 (26.66%) and 5 cases invasive squamous cell carcinoma (8.33%). We observed that the expression of p16^{INK4A} and Ki-67 were positively associated with CIN grade. p16^{INK4A} expressions increased significantly with high-risk HPV infection. We observed a positive correlation between the expression of the p16^{INK4A} and Ki-67. **Conclusion**: In our study, the expression of p16 and Ki-67 were positively related to the CIN grade. p16^{INK4A} expressions of high-risk HPV specimens significantly increased more than Ki-67. Therefore, in the diagnosis of CIN and high-risk HPV infection, p16^{INK4A} can be a useful biomarker. **Key words**: P16^{INK4A}, KI-67, CERVICAL INTRAEPITHELIAL NEOPLASIA (CIN), HIGH RISK HUMAN PAPILLOMA VIRUS (HPV-HR)

Cancerul cervical este al doilea cancer ca frecvenţă pe plan mondial (1,2) şi pe locul trei în Europa. În Uniunea Europeană există variaţii mari ca incidenţă şi mortalitate, cea mai mare mortalitate fiind înregistrată în România (13,7/100.000 femei/an) (3). Având în vedere aceste aspecte este de înţeles interesul deosebit pentru diagnosticarea precoce a leziunilor cervicale preinvazive în vederea scăderii morbidităţii şi mortalităţii prin acest tip de cancer.

Diagnosticul de certitudine al neoplaziei intraepiteliale cervicale (CIN) impune examen histopatologic, încadrarea leziunilor realizându-se în conformitate cu terminologia utilizată la nivel internaţional (4). Detectarea şi gradarea leziunilor poate fi uneori dificilă, modificările inflamatorii şi hormonale de la nivelul colului uterin, dimensiunea redusă a probelor sau prezenţa unor focare mici de CIN putând crea dificultăţi de diagnostic (5).

Scopul acestei cercetări este de a evalua expresia proteinelor $p16^{INK4a}$ şi Ki67 în CIN şi corelaţia acestora cu infecţia HPV-HR (high risk human papilloma virus), în vederea studierii potenţialului de proliferare celulară accentuată prin prezenţa HPV-HR şi dereglarea ciclului celular urmare a activării expresiei oncogenelor virale, evenimente precoce în mecanismul carcinogenic.

MATERIAL ŞI METODĂ

Dintr-o cohortă de 393 de paciente care s-au prezentat la Spitalul de Obstetrică şi Ginecologie Cuza-Vodă Iaşi în perioada ianuarie 2008-decembrie 2009, au fost studiate 60 de paciente cu vârste cuprinse între 22 şi 67 de ani. Lotul de studiu a fost investigat prin biopsie ţintită colposcopic şi genotiparea HPV. Examenul histopatologic şi imunohistochimic au fost realizate în Laboratorul Disciplinei de Morfopatologie al UMF „Gr.T. Popa", Iaşi. Genotiparea HPV s-a efectuat în cadrul Laboratorului de Inginerie Genetică Virală a Institutului de Virusologie „Ştefan S. Nicolau", Bucureşti.

Pentru examenul histopatologic biopsiile au fost fixate în formol tamponat, incluse la parafină şi apoi colorate cu hematoxilină-eozină (H-E). Diagnosticul histopatologic a fost stabilit în conformitate cu terminologia CIN.

Pentru genotiparea ADN HPV s-a utilizat tehnica PCR (Roche, Linear Array HPV Genotyping), în fiecare rundă fiind incluse controale pozitive şi negative.

Examenul imunohistochimic a utilizat anticorpii $p16^{INK4a}$ (MTM, clona E6H4TM) şi Ki-67 (Dako, clona MIB-1). Coloraţiile imunohistochimice s-au realizat prin metoda Avidin-Biotin Complex. Vizualizarea cu DAB a permis evidenţierea $p16^{INK4a}$ şi a Ki67 sub forma unui produs de reacţie de culoare brună. În fiecare serie au fost incluse controale negative şi controale pozitive.

Imunomarcajul pentru $p16^{INK4a}$ nuclear +/- citoplasmatic, a fost interpretat utilizând un scor semicantitativ (6) :

- 0- rezultat negativ 0%-5% celule imunomarcate ;
- 1- pozitivitate focală/izolată sau pozitivitate difuză întâlnită în 1/3 inferioară a epiteliului ;
- 2- pozitivitate difuză în 2/3 inferioare ale epiteliului ;
- 3- pozitivitate difuză în toată grosimea epiteliului.

Imunomarcajul pentru Ki-67 a fost clasificat în patru clase în raport cu extinderea colorării nucleare în grosimea epiteliului, în baza următorului scor semicantitativ (7).

- 0- rezultat negativ, imunomarcarea exclusivă a celulelor parabazale ;
- 1- imunomarcaj nuclear prezent în 1/3 inferioară a epiteliului ;
- 2- imunomarcaj nuclear prezent în 2/3 inferioare ale epiteliului ;
- 3- imunomarcaj nuclear prezent în toată grosimea epiteliului.

REZULTATE

Distribuţia cazurilor în raport de examenul histopatologic a fost următoarea : 7 cazuri cu aspect normal (11,66%), 18 cazuri cu CIN1 (30%), 14 cazuri cu CIN2 (23,33%), 16 cazuri cu CIN3 (26,66%) şi 5 cazuri de carcinom scuamo-celular invaziv (CSC) (8,33%).

Rezultatele genotipării HPV au fost gru-

pate în raport cu grupa de risc şi diagnosticul histopatologic (fig. 1). Infecţia cu HPV-HR a fost întâlnită într-un singur caz cu col normal histopatologic (14,28%), în 61,11% din cazurile de CIN1 (11/18), în 92,85% din CIN2 (13/14 cazuri) şi în toate cazurile cu CIN3 (16 cazuri) şi CSC (5 cazuri).

Supraexpresia p16^{INK4a} a fost evidenţiată în 45 de cazuri (75%), dintre care 11 cazuri cu scor 1 (fig. 2), 14 cazuri cu scor 2 (fig. 3) şi restul de 20 cazuri cu pozitivitate difuză în întreaga grosime a epiteliului (scor 3) (fig. 4). Rezultatele imunomarcajului pentru p16^{INK4a} în raport cu diagnosticul histopatologic sunt prezentate în figura 5.

Expresia proteinei Ki-67 a fost observată în 37 de cazuri (61,66%), 9 cazuri au prezentat scor 1 (fig. 6), 13 cazuri scor 2 (fig. 7) şi 15 cazuri scor 3 (fig. 8). Distribuţia imunomarcajului pentru Ki-67 în ra-

DISCUŢII

Analiza morfologică a biopsiilor cervicale rămâne standardul de aur în diagnosticarea şi gradarea neoplaziei intraepiteliale cervicale, stabilirea conduitei terapeutice în cazul leziunilor cervicale intraepiteliale de grad înalt depinzând de confirmarea histopatologică a CIN. Aspectele histopatologice ale neoplaziei intraepiteliale de grad înalt (CIN2/CIN3) sunt bine stabilite, dar uneori dimensiunea redusă a biopsiilor cervicale, prezenţa unor focare mici de CIN sau modificările inflamatorii şi hormonale întâlnite la nivelul colului uterin pot pune probleme de diagnostic diferenţial între modificările benigne şi neoplazia scuamoasă intraepitelială, precum şi în stabilirea gradului neoplaziei intraepiteliale (8,9).

Proteina $p16^{INK4a}$, reprezintă cel mai studiat şi mai promiţător biomarker al neoplaziei intraepiteliale cervicale fiind utilizat şi ca marker surogat al infecţiei HPV-HR. Proteina $p16^{INK4a}$ este un inhibitor al ciclin dependent kinazelor (CDK), fiind supraexprimată atât în neoplazia intraepitelială cât şi în carcinomul cervical, ca rezultat al interacţiunii oncoproteinei E7 a HPV-HR cu proteina supresor tumorală pRb (10,11,12).

Numeroase studii recente au stabilit valoarea $p16^{INK4a}$ ca marker surogat al infecţiei HPV-HR şi al CIN (13,14,15,16,17). Acestea au arătat că $p16^{INK4a}$ este supraexprimată în majoritatea leziunilor cervicale, iar statusul imunoreactivităţii permite diferenţierea dintre infecţiile HPV-LR (low risk human papilloma virus) şi HPV-HR (17).

În studiul de faţă am investigat distribuţia şi intensitatea imunomarcajului pentru $p16^{INK4a}$ în neoplazia intraepitelială cervicală şi am încercat stabilirea unei corelaţii între supraexpresia $p16^{INK4a}$ şi infecţia HPV-HR.

Rezultatele noastre au arătat o supraexpresie a $p16^{INK4a}$ în 10 (55,55%) din cele 18 cazuri de CIN1. Dintre acestea 7 au prezentat scor 1 şi 3 cazuri scor 2. În cele trei cazuri cu scor 2 supraexpresia macată a $p16^{INK4a}$ poate indica un risc crescut de progresie a leziunilor. Majoritatea cazurilor

de CIN1 p16^{INK4a} negativeau fost şi HPV-HR negative, unul singur prezentând infecţie HPV-HR.

În 71.42% din cazurile cu neoplazie intraepitelială de grad înalt (CIN2/CIN3) am întâlnit supraexpresia marcată a p16^{INK4a} (scor 2, 3). Excepţie au făcut patru cazuri cu CIN2 în care marcajul pentru p16^{INK4a} a fost observat doar în treimea inferioară a epiteliului (scor 1), unul dintre aceste cazuri fiind HPV-HR negativ. În schimb toate cele cinci cazuri de carcinom scuamocelular invaziv au prezentat scor 3.

Rezultatele obţinute susţin faptul că acest biomarker poate fi util în identificarea mai precisă a gradului neoplaziei intraepiteliale pe secţiunile histologice şi în plus poate reduce variaţia în interpretarea leziunilor cervicale. Aceste rezltate susţin deasemenea faptul că p16^{INK4a} poate fi utilizat ca marker surogat al infecţiei HPV-HR, 95,65% dintre cazurile HPV-HR pozitive prezentând supraexpresia p16^{INK4a}.

Pentru creşterea acurateţii diagnosticului CIN s-au efectuat numeroase studii care au avut drept ţintă antigenul Ki-67 ca marker al proliferării celulare (18,19). Ki-67 nu este specific unei anumite faze ale ciclului celular, fiind exprimat în toate etapele active ale acestuia, exceptând faza G_0 (20,21).

Infecţia HPV activează progresia ciclului celular al gazdei ceea ce are un impact direct asupra expresiei markerilor de proliferare în sensul creşterii acestora. Studii realizate pe biopsii cervicale au demonstrat că distribuţia şi indexul Ki-67 creşte odată cu gradul leziunii, atingând un maxim în cazul carcinomului scuamo-celular invaziv (CSC) (22,23).

În leziunile intraepiteliale cervicale prezenţa celulelor Ki-67 pozitive creşte dinspre stratul parabazal (unde sunt întâlnite şi în cazul epiteliului normal) spre straturile intermediare şi superficiale odată cu creşterea gradului leziunii, conferindu-i acestui marker un rol important în diferenţierea neoplaziei intraepiteliale cervicale de epiteliul cervical normal, metaplazic, atrofic sau cu modificări reactive (22).

În studiul nostru toate cazurile cu modificări benigne şi 14 dintre cazurile cu CIN1 au fost negative la marcarea cu Ki-67. Creşterea indexului de proliferare, evidenţiat prin prezenţa marcajului cu Ki-67 a fost întâlnit în 4 (22,22%) dintre cazurile de CIN1, 12 (85,71%) dintre cazurile cu CIN2 şi în toate cazurile (100%) cu CIN3 şi CSC. Se observă o corelaţie clară între numărul de cazuri Ki-67 pozitive şi creşterea gradului leziunii, cu o mică diferenţă între cazurile cu CIN2 şi CIN3. În schimb diferenţa este clară între cazurile cu CIN1 şi cele cu CIN2. În toate cazurile cu CIN1, marcajul pentru Ki-67 a fost întâlnit în treimea inferioară a epiteliului (scor 1), în timp ce în leziunile de grad înalt imunomarcarea s-a observat în 2/3 superioare ale epiteliului (scor 2 şi 3).

Combinarea acestor doi markeri, Ki-67 şi p16^{INK4a}, alături de genotiparea HPV reprezintă instrumente utile în identificarea leziunilor CIN oculte, în verificarea şi confirmarea diagnosticului histopatologic în cazurile echivoce, crescând astfel acurateţea interpretării histopatologice a biopsiilor cervicale şi instituirea unui tratament adecvat (24).

CONCLUZII

Rezultatele noastre indică existenţa unei corelaţii directe între activitatea proliferativă (Ki-67) şi gradul displaziei cervicale, precum şi asocierea supraexpresiei p16^{INK4a} cu prezenţa unei leziuni de grad înalt şi a infecţiei HPV-HR- elemente relevante în succesiunea secvenţelor mecanismului patogenic al carcinogenezei cervicale.

COMPARATIVE STUDY CONCERNING FOOD INTAKE IN A GROUP OF PEOPLE WITH DYSLIPIDEMIAS *VS.* A WITNESS GROUP IN THE TÂRGU NEAMŢ AREA (Abstract): The aim of the study was to find a correlation between the consumption frequency of the main food groups and the presence of dyslipidemia as compared to a witness group without dyslipidemias. **Material and method**: For this study we have considered a number of 678 people, divided in two groups: 339 with dyslipidemias and 339 without dyslipidemias, each of the two groups comprising 137 subjects from the rural area and 201 from the urban area, through the questionnaire method. **Results**: The involved people have been questioned about the consumption of milk and related products (cheese), meat and related products (beef and pork), fish and related products and fruits. Regarding the fruit consumption, in the urban area, we have found slightly increased values in the witness group of the percentages of those who eat them daily and 4-6 times a week as compared to the group with dyslipidemias. **Key words**: DYSLIPIDEMIAS, CHEESE, FISH, FRUITS

CORRELATION AMONG CHRONOLOGICAL AGE, DENTAL AGE AND CERVICAL VERTEBRAE MATURITY IN ROMANIAN SUBJECTS

CORRELATION AMONG CHRONOLOGICAL AGE, DENTAL AGE AND CERVICAL VERTEBRAE MATURITY IN ROMANIAN SUBJECTS (Abstract): **Aim:** The purpose of this study was to assess the correlation among the chronological age, the dental age and the skeletal maturity in adolescents and young adults. **Materials and methods**: The material consisted of panoramic and lateral cephalometric radiographs of 221 subjects, 146 girls (mean age 13.79 ±2.90) and 75 boys (mean age 13.46 ±2.82), inhabitants of Mures County (Central Romania). The chronological age was defined as the time from birth to the day the radiographs were taken. The dental age was evaluated according to Demirjian's method for third molars mineralization stage. Skeletal maturity was evaluated on cephalometric radiographs using the cervical vertebrae maturation (CVM) method. Descriptive statistical and linear regression analysis was performed and a coefficient of correlation was calculated. **Results**: The mean values obtained for cervical stages for boys and girls were significant ($p=0.0171$). The third molar mineralization seems to be highly correlated with the gender's chronological age for the whole group and for both genders as well ($p<0.0001$). The medium age of the cervical maturation showed to be younger in girls than in boys in CS1, CS3, CS5 and CS6 stages. In CS4 stages female subjects are in advance with almost 12 months, these subjects start (CS1) and end (CS6) the cervical maturation at a younger age. **Conclusions:** The results indicate that significant correlation exist between the chronological age and the dental age when crown development ends and between the chronological age and CVM (CS1 and CS6 stages for girls and CS2 and CS5 stages for boys). Keywords: DENTAL AGE, CERVICAL MATURITY, DEMIRJIAN INDEX, CHRONOLOGICAL AGE, MOLAR MINERALIZATION.

The assessment of the developmental stage of children, adolescents or young adults can be useful in many fields of medicine, even though it is difficult to do it because of the individual variation of overall developmental processes. Children with the same chronological age may show differences in the developmental stages of different biological systems (1). Assessing maturational status, whether the pubertal growth spurt of a patient has been reached or completed, can have a considerable influence on diagnosis, on treatment goals, on treatment planning, and on the eventual outcome of the orthodontic treatment (2).

Considerable variations in the development among children of the same chronological age have led to the concept of bio-

logic or physiologic age. The physiologic age is the registry of progress towards maturity that can be estimated by somatic, sexual, skeletal and dental maturity (3).

The dental age has been defined in the literature as "the subject's estimated age based on the level of tooth mineralization during the developmental process or on the eruption stage" (4). There were proposed many methods to asses this parameter: the stage of tooth eruption, the radiographic assessment of the length of the tooth crown and of the root (5). The mineralization of permanent teeth has been studied by a number of researchers (6). This type of examination can be easily done in everyday practice because the panoramic radiographs are usually a part of dental examination and there is no need of additional investigations. The dental age assessment based on tooth calcification visible on a radiograph was described by Demirjian et al. (7). Although this one is the most widely used method, it was formulated for the French Canadian population. The method evaluates the development of seven mandibular teeth from a panoramic radiograph and calculates dental age. Various researchers have tested the applicability of this method on different populations and certain correlations in patients with other racial background than the one this method was described for were found (8, 9). On the other hand, some authors reported significant differences between the dental age of French Canadian population and other populations (10, 11).

However, the study of the dental development remains a reliable method, because the development of a tooth is much less affected than other tissues by endocrine disorders or other developmental problems. Several studies concluded, that children with sexual, systemic or congenital disorders show small deviations in timing of dental development compared with healthy subjects (12, 13).

The degree of skeletal development is a reflection of the degree of physiological maturation of a subject (14). The bone age was shown to be as important as the chronological age in evaluating a patient's physical development (15). The skeletal maturation can be assessed usually using radiological methods; the classical one is based on the analysis of the hand-wrist radiographs (16, 17).

A disadvantage of this method is that it requires additional radiographic images and exposure to radiation beside those used for an orthodontic diagnosis. A commonly used method nowadays is based on the radiological assessment of cervical vertebrae outlines, the so called cervical vertebrae method (CVM). The size and shape of C2, C3 an C4 vertebrae are analyzed and the skeletal age is divided in six stages (18). This method of assessment of skeletal maturity does not require extra radiation exposure for the patient, because the analysis can be performed on lateral cephalometric radiographs, which are often used in the orthodontic diagnosis.

The aim of this study was to find a correlation between the third molar mineralization stage and the cervical vertebral maturity in Romanian subjects and to evaluate if radiographic evaluation of the third molar's development can be useful in the chronological age determination.

MATERIAL AND METHODS

After the research protocol was established, it was approved by the Ethical Committee of Scientific Research of the University of Medicine and Pharmacy from Tirgu Mures. A written consent was ob-

tained from each patient or their parents/legal representative in order to use patient's radiographs for this study.

Thus, two hundred twenty-one subjects, 146 girls (mean age 13.79 ±2.90) and 75 boys (mean age 13.46 ±2.82) were selected from patients referred for an orthodontic treatment at the Orthodontic Department of Faculty of Dentistry, University of Medicine and Pharmacy from Tîrgu Mureș, Romania. For each subject the digital panoramic and the lateral cephalometric radiographs were analyzed. The digital radiographic images were performed with Pax Flex 3D, Vatech X-ray machine, the exposure time was 12,9 seconds, at 80kVp and 9.0mA. The dental imaging software used was EasyDent. By using digital radiographs, it allowed us to enlarge certain parts of the images and perform a clear tracing of the bones or of the intraosseous dental structures.

The inclusion criteria were: (1) children of Romanian origin, (2) no history of orthodontic treatment before this radiographic examination, (3) good general health (4) no growth affecting hormonal or systemic disease, (5) good quality of lateral cephalometric and panoramic radiographs, (6) no history of trauma or surgery in cephalic or cervical region.

The chronological age was calculated based on the date of birth and the amount of time that passed from birth to the day of the radiography. The obtained values were rounded down and noted in years and decimal points.

The dental age was described on panoramic X-rays, using the Demirjian's method. The development of the four third molars was assessed on panoramic radiographs by means of the eight-grade scale according to Demirjian's system (fig. 1). Every determination was performed once by every author and if the difference exceeded one developmental stage, a lower stage was chosen. The tooth calcification stages were rated from A to H and a numeric value was assessed for each stage from 0 to 8 (A=0 to H=8). For each molar a stage was determined and from the obtained values a medium value was calculated for every subject (19). When the third molars mineralization stages were statistically analyzed and correlations were defined, cases with agenesis and molars in the first stage (bud-stage) mineralization were not included in statistical analysis.

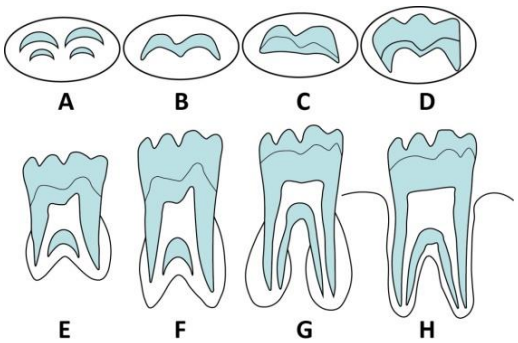

Fig. 1. The classification of the degree of molar tooth mineralization according to Demirjian et al.

The skeletal maturation stage was evaluated using the skeletal vertebrae method (CVM), by tracing the outlines of three cervical vertebrae (C2, C3 and C4) on lateral cephalometric radiographs. The tracing was performed visually by enlarging the cervical region on digital radiographs. The presence or the absence of concavity at the lower border of C2-C4 vertebrae as well as the shape of the vertebral bodies of C3 and C4 vertebrae (trapezoidal, horizontal, square and vertical) were analyzed. Six maturation stages were described (CS1 – CS6) and

numeric values were added for each stage (CS1=1,…CS6=6) (18, 20). (fig. 2)

All data were introduced in Excel and a statistic analysis was performed using the Excel Data Analysis package. Than a main statistic interpretation was performed; the mean values were calculated for the chronological age and for the cervical vertebrae maturation separate per genders and for the whole study group. A descriptive statistical and linear regression analysis was performed and a coefficient of correlation was calculated. A Student-test was used to compare the mean values of the chronological age and the dental development stages within different skeletal maturation stages; $p<.05$ was considered significant. A Chi test was used to study the association between the cervical vertebrae maturation and the dental calcification for girls and boys separately and for the whole group. Pearson's *r* correlation coefficient was calculated for the studied variables.

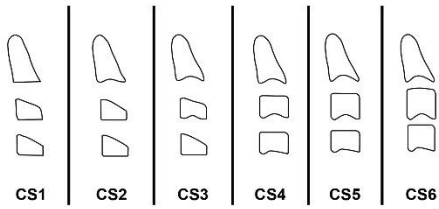

Fig. 2. The cervical vertebrae maturation stages

RESULTS

Comparing the mean values for all the studied variables between the two genders, chronological age and Demirjian index showed no statistical significance (p=0.41-0.43). The mean values obtained for cervical stages for boys and girls were significant (p=0.0171).

TABLE I

The mean values for the studied variables for boys, for girls and for the whole group (95% confidence interval)

Variable/group	Mean values			Probability of the test (p) between genders
	male	female	whole group	
Chronological age	13,46 ± 2,825	13,79 ± 2,903	13,68 ± 2,875	0.4134
Cervical stages	3,45 ± 1,445	3,95 ± 1,468	3,78 ± 1,476	0.0171
Demirjian's index	2,94 ± 1,348	3,08 ± 1,088	3,03 ± 1,186	0.4342

The mean values for the chronological and the dental ages for every cervical stage (CS1-CS6; tab. II) and tooth calcification stage (B-H; tab. III) were also calculated. As agenesis of third molar has an increasing tendency, we have included the modifications of Demirjian's method assigning scores of "0" in case of the absence of the third molar and "1" in case of the presence of a radiolucent bud (21). This is the reason why we excluded from our further statistical interpretation the subjects with agenesis of the third molar and those who had molars in a bud-stage.

A linear regression analysis and correlation was used to study the association between the chronological age and different cervical maturation stages (tab. IV) for girls and boys separately and for the whole group as well.

TABLE II

The mean values of the chronological age for different cervical maturation stages

Cervical stage/gender	n=75	n=146	Chronological age	
	males	females	males	females
CS1	7	9	12,00 ± 2,02	10,12 ± 1,85
CS2	16	20	11,23 ± 1,80	11,33 ± 2,84
CS3	12	19	13,46 ± 2,58	12,87 ± 2,78
CS4	23	46	13,19 ± 2,00	14,11 ± 2,15
CS5	10	25	15,37 ± 2,12	14,66 ± 1,49
CS6	7	27	18,13 ± 2,26	16,13 ± 2,85

TABLE III

The mean values of the chronological age and its correlation with different tooth calcification stages (* statistically strong significance)

Variable/tooth calcification stage	Mean value of chronological age		Probability of the test (p)	
	females	males	females	males
B	11,18 ± 1,89	11,76 ± 1,82	0.6085	0.1786
C	13,59 ± 1,36	11,95 ± 1,69	0.0004*	0.1476

The correlation coefficients between the chronological age and different tooth mineralization stages (B-H) for genders (*statistically strong significance)

Subjects	Correlation coefficient (r)	Probability of the test (p)
Whole group (n=221)	0.7065	<0.0001*
Male subjects (n=75)	0.7178	<0.0001*
Female subjects (n=146)	0.7078	<0.0001*

DISCUSSION

When the age determination is required, correlation amongst the chronological age, the skeletal maturity and the tooth development related dental age can be helpful. The evaluation of the chronological age becomes simple if we are aware of patient personal data. The intraosseous tooth development is mostly genetically coordinated and seems to be independent of patient's general conditions and nutrition (22). After the young permanent dentition is complete, in adolescent period, the only unerupted permanent tooth remains the third molar. Even though the age estimation using dental methods have shortcomings and the third molars can have individual pattern of calcification rhythm, formation or intraosseous position, it remains the only tooth which can help in the dental age evaluation in post-pubertal age and for young adults (23).

The determination of skeletal maturation is extremely important in many fields of medicine. In pediatric dentistry and orthodontics, it will help in right the timing of treatment and it will make possible an individualized treatment planning. In forensic sciences it may help in emerging or young adult's corps or skeletons age identification. Beside the hand-wrist method, CVM is a valid indicator of skeletal growth during the pubertal period (24).

Although there is a strong relationship between the skeletal and the somatic maturation, this correlation seemed to be inconclusive between dental age and skeletal maturity (25). Studies revealed different concordance between dental age and skeletal maturity, which can be explained by differences in the evaluation methods, age and racial background of the studied subjects (26, 27, 28).

The selected subjects in our study were referred for orthodontic treatment; the

mean age of subjects of different gender was almost the same and the mean age of the studied group was 13,68 ± 2,875, an age when the permanent dentition is about to be completed (tab. I). When the correlation between the mean age and the skeletal maturity was assessed, the medium age of the cervical maturation showed to be younger in girls than in boys in CS1, CS3, CS5 and CS6 stages, in CS4 stages female subjects are in advance with almost 12 month. The female subjects start (CS1) and end (CS6) the cervical maturation at a younger age (tab. II)

Spearman's rank correlation coefficient (tab. IV) revealed a good relationship between the chronological age and the cervical stages in males (r=0.68, p=0.00) for CS2 and in females (r=0.80, p=0.00) for CS6. The lowest correlation was observed in CS1 for males (r=0.22 p=0.63) and in CS2 for females (r=0.27 p=0.23).

Many authors proved that the *cervical vertebrae maturation* (CVM) has a high level of correlation with individual skeletal maturation (29, 30) and the greatest increase in mandibular length occurred during the pubertal growth spurt and that this could be assessed during the interval between CS3 and CS4 (31, 32). Based on our findings, the pubertal spurt appears with almost one year earlier in female subjects and the whole skeletal maturation is more accelerated in girls.

Correlations between the chronological age and the cervical vertebrae maturation in different studies revealed that this depends on the subject's racial background. Most of the studies found correlation coefficient: a low correlation was found in Chinese (33) and Brazilian (34) subjects, high correlation was found by other several studies (35, 36, 37, 38).

Analyzing the correlation between the chronological age and the different stages of the cervical maturation in both genders, we concluded, that the cervical vertebrae maturity increased as the chronological age increased. The cervical maturation starts earlier in girls and the pubertal growth spurt (CS3 stage) takes place earlier in girls, too: the difference between the medium ages is around 6 months. Another interesting information is that the cervical maturation ends (CS6 stage) with almost two years earlier in female subject, which means that the onset of puberty is related to gender. Statistically strong significance was found in the CS1, CS4 and CS5 stages in female and CS2, CS4 stages in male subjects. The same results were found by several other studies (39, 40, 41).

Analyzing the mean ages for the different CVM stages and the third molar mineralization stages we observed that crown formation of the third molars (D stage) became completed around the pubertal growth spurt (CS3 stage) in males, meanwhile in female subjects this was observed in a later stage (CS4 stage) of cervical maturation. In the last stage of the cervical maturation (CS6 stage) where the skeletal maturation comes to end, two-third of the third molar root length (F stage) is developed in both genders.

Analyzing the significance of statistical data correlation between the chronological age and the third molars mineralization in different skeletal maturation stages, we found that the female subjects present stronger correlations in the second part of cervical maturation (CS4-CS6 stages), meanwhile for male subjects' significant correlations were observed in CS2 and CS4 stages. The third molar mineralization seems to be highly correlated with the gen-

der's chronological age for the whole group and for both genders as well ($p<0.0001$).

Studying the mean values for Demirjian's index (tab. III), there were slightly differences between the two genders at the commencement of the third molar mineralization (B stage) or at the age of complete crown formation (D stage), but the root development (G stage) ended earlier in male subjects. A significant statistical probability was found in D stage ($p<0.0001$) of mineralization for both genders and in F stage ($p=0.0004$) for the female subjects. The assessment of dental mineralization in order to evaluate the dental age seems to be a more accurate method than the study of sequence and of the phenomenon of eruption (42).

Studying the relationship between the third molar development and the chronological age, several studies found statistically significant correlations in the third-molar development between males and females especially in stages D and G (43) or in stages E-G (44). Regarding the age of tooth development, as most of the studies concluded, the female subjects present a delayed development of both the upper and lower third molars compared to the boys (45, 46, 47).

CONCLUSIONS

The number of the studied cases and the fact that they all come from one county can be considered limitations of our study. In order to evaluate the correlation among the chronological age, the dental development and the skeletal age for Romanian subjects, a higher number of subjects from other parts of the country should be selected.

Based on our findings, we conclude the following:

- The root development ended earlier in female subjects, D and F stages of tooth calcification showed significant correlation with the chronological age.
- A strong significant correlation between the chronological age and the tooth mineralization stages was found in D stage of Demirjian's classification (crown formation is complete), for both genders
- The crown formation of the third molars is completed at the age of pubertal growth spurt (CS3) in males and in a later stage of cervical maturation (CS4 stage) in females
- At the age of complete skeletal maturation (CS6 stage) two-third of the third molars roots are developed
- The commencement (CS1) and the end (CS6) of the cervical vertebrae maturation happens earlier in female patients, the last stage of the cervical maturations ends (CS6 stage) with almost two years earlier in female subject.
- A significant correlation between the chronological age and CVM was found in CS1 and CS6 stages for girls and CS2 and CS5 stages for boys.

EVALUATION OF THE SYNTHESIS AND STRUCTURE OF NEW AZETIDIN-2-ONES OF FERULIC ACID (Abstract): **Aim:** To synthesize some new azetidin-2-ones of ferulic acid and to evaluate them from physicochemical and spectral point of view. **Material and methods:** The synthesis was carried out in several steps: (i) obtaining the ferulic acid chloride; (ii) obtaining the ferulic acid hydrazide with hydrazine hydrate (98%); (iii) condensation of ferulic acid hydrazide with different benzaldehydes (2-hydroxy-/2-nitro-/4-chloro-/4-fluoro-/4-bromo-benzaldehyde) in order to obtain the corresponding hydrazones; (iv) cyclization of ferulic acid hydrazones with chloroacethyl chloride in freshly distilled toluene medium and in the presence of triethylamine, resulting in the corresponding azetidin-2-ones. **Results**: Six new azetidin-2-ones of ferulic acid were synthesized. They were characterized in terms of their physicochemical properties and their structure was confirmed by IR and ^{1}H-NMR spectroscopy. **Conclusions:** Six new azetidin-2-ones of ferulic acid were synthesized, physicochemically characterized and validated spectrally. **Keywords:** FERULIC ACID, AZETIDIN-2-ONES, SPECTRAL VALIDATION.

In the present days we are witnessing to a growing interest of researchers in the use of antioxidants in reducing oxidative stress.

Development of new compounds including in their structure biologically active entities, especially heterocyclic systems is a major concern for researchers. In this context, special attention is directed to azetidin-2-one derivatives.

It is known that the azetidin-2-one ring is the common structure of beta-lactam antibiotics such as penicillins, cephalosporins, carbapenems, monobactams and nocardicine used as chemotherapeutic agents in the treatment of infectious diseases (1). Recent studies assign to this heterocyclic ring many other biological effects: hypoglycemic, antitumor, anti-HIV, anti-inflammatory, analgesic and antioxidant actions (2, 3).

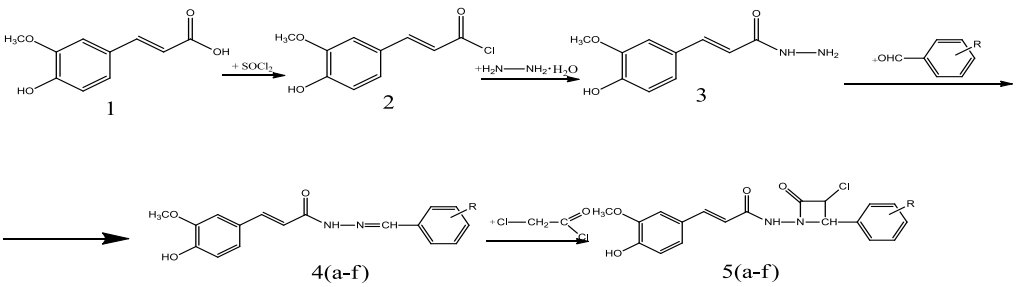
On the other hand, ferulic acid (4-hydroxy-3-methoxy-cinnamic acid) is a phenolic compound widely distributed in the plant world. Due to its antioxidant effect, ferulic acid may protect DNA and lipids from oxidation by reactive oxygen species and could be useful in the prevention and treatment of several oxidative stress-related disorders including Alzheimer's disease, diabetes mellitus, cancer, hypertension, and atherosclerosis (4, 5).

The aim of this study was to develop new compounds with heterocyclic structure and improved antiinflammatory and antioxidant effects. In order to achieve this goal new azetidin-2-one derivatives of ferulic acid there were synthesized.

MATERIAL AND METHODS

Ferulic acid, thionyl chloride, hydrazine hydrate, aromatic aldehydes (2-hydroxy-/2-nitro-/4-chloro-/4-fluoro-/4-bromo-benzaldehyde), chloroacetyl chloride, triethylamine, organic solvents (*p.a.* quality) were purchased from Sigma Aldrich Company and Fluka Company. All reagents and solvents were used without previous purification. For monitoring the reaction, TLC silica gel 60 F_{254} plates, purchased from Merck Company, were used.

Synthesis of the azetidin-2-one derivatives of ferulic acid: Ferulic acid was reacted with thionyl chloride to obtain the ferulic acid chloride that was next treated with hydrazine hydrate 98% to obtain ferulic acid hydrazide. By condensation with different aromatic aldehydes (2-hydroxy-/2-nitro-/4-chloro-/4-fluoro-/4-bromo-benzaldehyde) the corresponding hydrazones (4a-f) were obtained. These hydrazones were cyclized with chloroacethyl chloride in freshly distilled toluene medium and in the presence of triethylamine to obtain the corresponding azetidin-2-ones (5a-f) (fig. 1) (6, 7, 8).



Compound	-R	Compound	-R
5a	-H	**5d**	-Cl(4)
5b	-OH(2)	**5e**	-F(4)
5c	-NO_2(2)	**5f**	-Br(4)

Fig. 1. Azetidin-2-one derivatives of ferulic acid synthesis

General procedure for azetidin-2-ones of ferulic acid synthesis. Over 0.025 moles (5 g) of ferulic acid and under continuous stirring 0.15 moled os thionyl chloride were added. The reaction mixture was maintained at 50^0C for 4 hours and the excess of thionyl chloride was removed by rotary evaporation. In the second step, over the ferulic acid chloride (0.05 moles) 0.25 moles of hydrazine hydrate 98% were added. The reaction mixture was maintained on ice bath for 2 hours and then at room temperature for another 2 hours, under continuous stirring. Then 15 mL of cold water were added and the precipitate was dried at room temperature. Finally, 0.015 moles (3 g) of ferulic acid hydrazide with a few drops of glacial acetic acid and 0.015 moles of aromatic aldehydes (2-hydroxy-/2-nitro-/4-chloro-/4-fluoro-/4-bromo-benz-

aldehyde) were refluxed for 13-20 hours in absolute ethanol. The reaction was monitored by TLC, using ethyl acetate:methanol:acetone:water (5:2:2:1) as solvent system. In the last step, the 0.0015 moles (0.5 g) of hydrazone with 0.0022 moles of chloroacethyl chloride, in the presence of triethylamine, were refluxed for 15-20 hours in toluene. The reaction was monitored by TLC, using dichloromethane:methanol (9:1) as solvent system. The obtained precipitate was washed with 1M hydrochloric acid, and the organic layer was dried on anhydrous magnesium sulphate and then washed with petroleum ether.

***Physicochemical characterization*:** The azetidin-2-one derivatives of ferulic acid were physicochemically characterized: melting point, output, molecular formula, relative mass, solubility in water and other organic solvents. The general synthesis was optimized in order to gain great output and advanced purity for the obtained derivatives. The reaction was monitored by TLC on 60 F254 silica gel plates, and spots were visualized by UV light at 254 nm. The melting point was determined by using Buchi M 565 (Buchi, Switzerland).

Spectral characterization: The IR spectra of the synthesized derivatives were recorded using a Fourier transform spectrometer, ABB-MB 3000 FT-IR MIRacle^{TM} Single Bounce ATR-crystal ZnSe, and the studied spectral range was between 4000–500 cm^{-1}, at a resolution of 4 cm^{-1}, 16 scans being carried out for each sample. The spectra were interpreted using the Horizon MB^{TM} FT–IR software (9, 10). For ^{1}H-RMN, the samples were dissolved in hexadeuterio-dimethyl- sulfoxide (DMSO-d_6) and the Bruker 400 MHz NMR spectrometer (Germany) was used. The spectral signals were automatically integrated and the chemical shift values were expressed in parts per million (ppm) relative to tetramethylsilane (TMS) as an internal standard. The spectra were interpreted using MestReNova software (11).

RESULTS AND DISCUSSION

The azetidin-2-one derivatives of ferulic acid are crystalline powders, colored in different shades of brown, very slightly soluble in dimethylsulfoxide (DMSO) and dimethylformamide (DMF), partially soluble in absolute ethanol, methanol, chloroform, acetone, dioxane and insoluble in distilled water, benzene and ethyl ether. The physicochemical and spectral characteristics are listed (tab. I, II).

The azetidin-2-one derivatives of ferulic acid were characterized by IR absorption. The FT-IR spectra revealed the presence of C-O stretching band cyclic at 1724–1734 cm^{-1}. The IR spectra also showed the characteristic absorption band of CH-N at 1380–1396 cm^{-1} and the characteristic absorption band of CH-Cl in the region 690–724 cm^{-1}. These data confirm the structure of derivatives and the successful azetidine ring formation.

The structure of derivatives is also supported by NMR spectra. The apparent resonance multiplicity is described as s (singlet), d (doublet), m (multiplet), dd (double doublet), and td (triple doublet) signal.

The signals of CH-Cl protons resonate as a doublet in a range of δ 4.92–5.04 ppm

and the protons linked by the N from azetidine ring (Ar-CH-N) exhibited a doublet at δ 5.24–5.54 ppm.

CONCLUSIONS

We synthesized six new azetidin-2-one derivatives of ferulic acid. The optimal reaction conditions for obtaining high yield and high purity compounds were established. The new derivatives were characterized by their physical constants (melting point, yield, molecular formula, molecular weight, solubility in different organic solvents). The chemical structure was confirmed proved by FT-IR and ^{1}H-RMN spectroscopy. All the obtained data encourage us to further investigate *in vitro* and *in vivo* these new azetidin-2-one derivatives of ferulic acid.

CAN THE EPIC FOOD FREQUENCY QUESTIONNAIRE BE APPLIED TO THE POPULATION IN ROMANIA? (Abstract): **Aim**: The application of the EPIC food frequency questionnaire to the population of Romania in order to obtain information about nutritional intake/dietary pattern. **Material and Methods**: EPIC Norfolk questionnaire (translated and adapted) was administered by an interviewer to 125 people, who also completed the 24-hour diet recall on two different days. In addition, data was collected in regards to anthropometry (weight, height, body mass index), as well as information related to other lifestyle factors, such as rural / urban, education, physical activity or income. Calculating the nutrients was done on the basis of tables published by the Ministry of Health. For statistical data processing the *SPPS 17.0* software was used. **Results**: The current rating refers to data obtained by analyzing the questionnaires for the 24-hour diet recall. The analysis of the kinds of food supported the correspondence with the original English questionnaire. By analyzing the energy and macronutrient intake through the both methods, depending on the area of origin, it appears that rural people consume a higher percentage of saturated fat ($p = 0.006$) and lower of insoluble fiber ($p = 0.042$) and carbohydrates ($p = 0.036$) compared to those in urban areas, which are statistically significant differences. On average, the intake of kcal/day was 1741.22, carbohydrates/day 201.66 g, respectively 56.13%, protein 88.33 g/day respectively 25.46%, fibers 17.25 g/day, fat 94.67 g/day respectively 18.28%, of which saturated fat 22 g/day (11.04%), monounsaturated 24.65 g/day (12.24%), polyunsaturated 10.48 g/day (5.3%); cholesterol 329.63 mg/day. **Conclusions**: The analysis in this phase of the study was necessary to equate the foods from the food frequency questionnaire EPIC with those consumed by the population of Romania expressed in the 24-hour diet recall and also to have a basis for comparison with food frequency questionnaires applied now and in 6-9 months in order to validate it. **Keywords**: FOOD FREQUENCY QUESTIONNAIRE (FFQ), NUTRIENTS, EPIC.

Accurately measuring of the dietary intake is considered to be the greatest challenge in nutritional epidemiology (1). Food frequency questionnaires are nutritional assessment tools, widely used in epidemiological studies since the early 90s, which investigate either the relationship between food intake and disease or the risk factors

(2). These nutritional assessment methods should be available, cheap, and easy to apply both by participants and investigators and should be able to collect information on a regular diet for an extended period of time (3). Precisely because they satisfy these conditions, food frequency questionnaires were largely used for epidemiological purposes (4). Food frequency questionnaires are retrospective and obtain information about the frequency of consumption from a specific list of foods and beverages, and may include or not estimates of the portions consumed (5). In large epidemiological studies, diet data obtained from food frequency questionnaires are compared with specific diseases such as cancer, or risk factors such as the total cholesterol and HDL-cholesterol. Food frequency questionnaires can also be used to identify food patterns associated with inadequate intake of specific nutrients (6). Because of the intra- and inter-individual variability, food frequency questionnaires covering the previous year are recommended for studies on wider populations.

Most questions are based on a selected list of foods and food groups with similar nutritional values. Lists of specific foods are based on food pattern of the population studied (7). Creating a food frequency questionnaire can be achieved either by modifying an existing questionnaire, or by creating one from scratch. Selecting the most informative food is important to prevent the establishment of long lists which would reduce the accuracy of the data obtained. The simplest method of making the list is to examine food composition tables and identify foods that contribute significantly to nutrient intake. Assessment of portion sizes is necessary to calculate the daily intake of nutrients. It is possible to specify a typical portion (100 g meat or ½ cup of rice) or to classify portion size as small, medium or large, using real models or reference units (8). The estimates derived from food frequency questionnaire data may present systematic errors and may not adequately represent the usual nutrient intake (9). Incorrect information can lead to the false association between nutritional factors and diseases and the validation of these questionnaires is therefore important.

The validity of questionnaires is generally assessed by comparing the data with a reference method (the most common method is the 24-hour diet recalls). Most validation studies have shown a strong correlation between nutrient intake estimates using the two methods (10, 11). However, other studies have reported a discrepancy between estimated energy intake and energy needs (12) and others have shown that the food frequency questionnaire cannot be recommended as a tool to assess the relationship between absolute intake of energy or protein and disease (13). Therefore it became important the use of biomarkers to assess dietary intake (14, 15, 16, 17). Age, gender, ethnicity and health status may affect the results of validation studies. It is therefore important that the population on which the questionnaire is validated to be identical to that for which it is intended (8).

MATERIAL AND METHODS

The Norfolk EPIC questionnaire is one of the most used food frequency questionnaires, created in 1988, validated and used to assess dietary intake on 25,639 participants, aged 40-79 years, and was completed between 1993 and 1997. The questionnaire consists of two parts. The first part is the food list (130 lines); each line has an attached portion size: average portion, standard unit or household unit. Food questionnaire lines are either individual or

combinations of individual foods or types of foods. Participants were asked to select a suitable frequency of food consumption for each line of nine categories of frequencies (from never or less than once a month up to 6 times per day). The second part contains further questions on the frequency or type of certain foods (18).

The process of translation and adaptation of the EPIC-Norfolk Food Frequency Questionnaire was done as directed by WHO (19). The Romanian version is conceptually equivalent to the English one. The final version was reached by following the implementation steps, forward translation from English to Romanian, back-translation from Romanian to English, pre-testing and cognitive interviewing (20).

A group of bilingual experts (expert panel) discussed each item. These experts also decided to introduce Romanian dishes similar in composition (from foods tables) and some Romanian brands similar to those in the original questionnaire. The food tables published in the Healthy eating guide on the web site of the Ministry of Health were used (21). Interviewers have organized a focus group for the application of the questionnaire in order to check that every question can be repeated in their own words.

The study began in January 2015 and continued for the next nine months. The 24-hour diet recall and the FFQ 1 were applied on 125 people. The second tranche of questionnaires was scheduled to be applied after 6 to 9 months.

Our translated and adapted questionnaire version contains 130 items (foods and drinks). These are categorized into 10 major food groups: meat - fish, bread - flavored biscuits, cereals, potatoes - rice - pasta, dairy products - fats, sweets - snacks, soups - sauce - sandwich spreads, drinks, fruits, vegetables. Certain foods from the list that are not commonly consumed in Romania have been replaced by other foods from the same food group category and with the same nutritional value (e.g. *beef burger* - minced meat croquette, or *halibut*, a fatty fish - trout); also food brand names were replaced with their Romanian counterparts.

Subjects were asked to specify the frequency for the consumption of these foods in the previous year. There are nine levels of frequency: never or less than once a month, 1-2 times per month, once a week, 2-4 times a week, 5-6 times a week, once a day, 2-3 times a day, 4-5 times a day, 6 times per day. Seasonal variability of dietary intake of fruits and vegetables has to be also taken into account, which is a complex issue in terms of reporting, given that some of them are consumed throughout the year and others in a greater degree during the summer. Therefore the 2ndfood frequency questionnaire application will be made in another season. The last section of the questionnaire contains questions that ask more details about certain foods (mainly those containing fats or cereals), vitamin and mineral supplements or brand names. We used the drawings from the healthy eating guide for estimating the portions.

In our study the questionnaire was applied on 125 adults (between 20-70 years), both sexes, in order to demonstrate its ability to estimate general dietary intake. The questionnaire was administered by an interviewer, face-to-face, after signing the informed consent. The 125 people completed a 24-hours diet recall on two different days. In addition, it obtained data linked to anthropometry (weight, height, body mass index), as well as information related to other lifestyle factors, such as environment rural / urban, education, physical activity or income. The data were imported into SPSS for analysis and descriptive statistics were

calculated to describe the general characteristics of the participants.

RESULTS

The analysis of macronutrient intake from both days of 24 hours diet recall, by area of origin shows that rural people consume a higher percentage of saturated fats (p=0.006) and lower insoluble fibers (p=0.042) and carbohydrates (p=0.036) compared to those in urban areas, which represent statistically significant differences (Table I).But in terms of physical activity, education level or average income, there have not been observed any statistically significant differences.

The analysis of macronutrient intake according to weight (normal weight, overweight, obese) shows there were statistically significant differences in terms of total daily fiber intake and polyunsaturated fats; in obese participants there was found a

higher intake of polyunsaturated fats and low total fiber per day, compared to other categories.

On average, the intake of kcal/day was 1741.22, carbohydrates 201.66 g/day, respectively 56.13%, protein 88.33 g/day respectively 25.46%, fibers 17.25 g/day, fat 94.67 g/day respectively 18.28%, of which saturated fat 22 g/day (11.04%), monounsaturated 24.65 g/day (12.24%), polyunsaturated 10.48 g/day (5.3%); cholesterol 329.63 mg/day (Table II).

alcohol %	232	0,40	0,00	2,03	0,00	19,70

The subjects were categorized according to the distribution of the intake (quartiles), as follows: carbohydrates <45%, 45-65%,> 65%, proteins <10%, 10-35%,> 35%, fats <30%,> 30%, fibers, <14 ‰ cal,> 14 ‰ cal and showed statistical significance according to BMI (obese) for carbohydrates and fibers (table III), but not according to area of origin. Most obese subjects fall within the 45-65% carbohydrates intake and fibers <14 ‰ cal, while most normal weight subjects consume > 65% carbohydrates and> 14 ‰ cal fibers.

As to the energy intake, it was found to be higher in normal weight versus overweight and obese patients, with statistically significant results (p = 0.001), but no differences were observed in terms of area of origin, physical activity or income.

DISCUSSION

Measurement of the usual food intake is necessary to establish the food pattern. The food frequency questionnaire is a useful tool in epidemiological studies because it allows a long-term assessment of diet and

investigating the diet-disease relationship. The questionnaire which this study is based on is EPIC Norfolk, which was translated and adapted for the people of Romania. To estimate nutrient intake it is necessary to use the tables with the nutrient composition of the foods reported by the participants, in two different ways (24 hours diet recall and FFQ).

In order to convert the estimate of food intake frequency to the nutritional values, there has to be constructed a database suitable for nutrients. Databases available in our country do not contain complete information. The 24 hours diet recall helps us to compare the English questionnaire to the Romanian one. The health eating guide published on the site of Ministry of Health helped us to visualize the portion size.

In this study there has been observed a higher consumption of saturated fat and cholesterol and a lower consumption of fiber as opposed to the recommendations from nutritional guides, and a higher consumption in subjects from rural areas compared to those in urban areas.

CONCLUSIONS

Although there are difficulties in calculating the absolute individual intake of nutrients using food frequency questionnaires, they are useful in obtaining information on population groups and to assess the usual intake of a range of foods. This preliminary study demonstrated the applicability of the EPIC questionnaire to a population of Romania, but the validation can be done after 6-9 months when the second FFQ is applied.

PRELIMINARY STUDY OF MEDICAL RESIDENTS' EVALUATION OF THEIR TRAINING PROGRAM REGARDING THREE-DIMENSIONAL IMAGING TECHNIQUES (Abstract): The **aim** of this preliminary study was to assess the residents' perception on their training program and on their knowledge regarding the use and interpretation of three-dimensional imaging techniques in their clinical practice. **Material and methods:** A multi-item questionnaire was distributed among 104 residents training in four medical specialties at the University of Medicine and Pharmacy "Grigore T. Popa" in Iaşi. **Results:** Fifty-five residents agreed to fill in the questionnaire, achieving a participating rate of 52.88%. The majority of the respondents (74.5%) declared to indicate classic CT scans to their patients. A significantly lower fraction of the participating residents (32.7%) affirmed to indicate CBCT scans. Electronic literature was the most common information source on the use of three-dimensional imaging (52.7%). Most of the residents declared that they cannot interpret correctly CT and CBCT scans (78.2%, respectively 83.6%). A significant percentage of the respondents considered that the level of training provided on the interpretation of CT and CBCT results is very low (49.1%, respectively 60.0%). **Conclusions:** The residents' perception of the quality of their education regarding 3D imaging modalities, along with their perception of their knowledge in this area, indicates the necessity to improve their didactic and practical training. A further extended survey will be conducted to evaluate the educational experience of residents from all medical specialties that use 3D imaging techniques in neck and head imaging. **Keywords:** THREE-DIMENSIONAL IMAGING, CT, CONE BEAM CT, RESIDENCY TRAINING PROGRAM.

During the last decades, three-dimensional (3D) imaging modalities have continually contributed to diagnostic purposes and treatment planning of various head and neck pathologies, providing non-distorted and non-overlapping visualization of the anatomy, with high resolution (1). Computed tomography (CT) rapidly became a first-line diagnostic test for numerous clinical conditions. Its utilization increased as its diagnostic capability expanded, raising concern about imaging-related financial costs and radiation risks (2, 3). Cone beam computed tomography (CBCT) was introduced as a new 3D imaging technology in the late 1990's (4, 5), offering a

lower dosage of radiation exposure compared to the classic CT, a low cost, and a quick scanning time (6-9). CBCT has been recently available in Romania, although not widely accessible yet, except for private radiology clinics. The availability of new technology requires physicians to be aware of its applications, impacting the quality of medical care they offer to their patients. The indication of three-dimensional imaging modalities should be performed based on a sound knowledge of its potential, benefits, and possible risks, hence the appropriate education and training becomes imperative for the physicians who will utilize and interpret the acquired data.

Therefore, the aim of this preliminary study was to assess the residents' perception on their training program and on their knowledge regarding the use and interpretation of 3D imaging techniques in their clinical practice.

MATERIAL AND METHODS

A questionnaire was applied to residents training in four medical specialties at the University of Medicine and Pharmacy "Grigore T. Popa" in Iaşi: Orthodontics and dentofacial orthopedics, Oral and maxillofacial surgery, Pediatric surgery, and Plastic surgery and reconstructive microsurgery.

The questionnaire contained 11 items which, aside from personal data (age, sex, and medical specialty), consisted in single response questions (Yes/No), Likert scale response questions and one multiple answer question. The items aimed to assess the use of 3D imaging techniques, the information sources in this area, the respondents' perception on their current knowledge and on the quality of the residency program regarding the topic.

All respondents were encouraged to answer all items honestly and they were assured of the preservation of their anonymity.

Collected data was analyzed using SPSS software version 16 for descriptive statistics and for correlations between variables.

RESULTS

Out of 104 residents training in the selected medical specialties, 55 agreed to participate in the present study, achieving a response rate of 52.88%. The participants' ages ranged from 25 to 41 years, with a balanced male/female distribution (about 4/5).

The majority of the respondents (74.5%) declared to indicate classic CT scans in their clinical practice. A significantly lower fraction of the participating residents (32.7%) affirmed to indicate CBCT scans. Fewer Plastic surgery and reconstructive microsurgery residents opted for CBCT, compared to the other three medical specialties (pairwise t-test, 95% confidence interval).

Most of the residents considered that they cannot interpret correctly CT and CBCT examinations (78.2%, respectively 83.6%).

The most common source of information regarding the use of 3D imaging modalities was electronic literature (52.7%), followed by printed literature (40%), congresses (40%), and courses (38.2%) (fig. 1).

A significant percentage of the respondents considered that the level of training provided by the residency program on the interpretation of CT and CBCT examination is very low (49.1%, respectively 60.0%) (tab. I).

The calculated mean scores for the level of training provided by the residency program are showed in Table II. The score

regarding CT results interpretation was higher when compared to CBCT, but the difference is not statistically significant (pairwise t-test, 95% confidence interval).

Minimum	1	1
Maximum	5	5
Std. Dev.	1	1

DISCUSSION

The results show a more pronounced lack of knowledge when referred to CBCT imaging, compared to classic CT. A noticeable preference of CT usage over CBCT can also be observed. Smith *et al.* (2011) report a consistent CBCT accessibility and training in orthodontic residency programs in the U.S (10), while Parashar *et al.* (2012) report a general trend of providing CBCT equipment and training in the U.S., British, and Australian dental education (11). Recently, the European Academy of Dento Maxillo Facial Radiology published a paper regarding the importance of proper training of dentists in the usage and interpretation of CBCT examination (12). Most dental and medical schools in Romania have recently adopted CBCT image acquisition and interpretation in oral and maxillofacial radiology courses. Nevertheless, while CT devices have been available in university hospitals in the past decades, CBCT equipment has only recently been introduced in Iaşi through private radiology clinics. To our knowledge, this new technology is yet not available in Romanian university hospitals, contributing to the limited knowledge of its applications and the lack of practical training among residents.

A proper education of medical residents regarding 3D head and neck imaging modalities should include information on acquisition of data, on the interpretation of the detailed information provided, a thorough knowledge of the anatomical structure as they appear on 3D scans, and how to analyze the findings (11-13). We consider that this will become a more prominent component of the residency curricula in the coming years, equipping residents to use, understand and interpret correctly 3D imaging techniques.

While this preliminary study provides insight into the nature of residents' perception of their knowledge and training program regarding 3D imaging procedures, there are certain limitations to it. Neither one of the medical specialties does include a radiology module in its program (as published on the official site of residency program trainings). However, their curricula include some lectures on imaging, mostly during surgical modules. The design of the present study did not take into account the timing of these lectures, and while a part of the respondents had already attended them, the rest of the participating residents had not. This may produce bias to the results. Our research did not reveal previous similar studies conducted in Romania, that preventing us for comparing the obtained results to other findings.

On personal discussions with the respondents, a clear interest in learning more about the latest trends in 3D imaging was observed, and also willingness to share information to improve their educational experience.

CONCLUSIONS

The residents' perception of the quality of their education regarding 3D imaging modalities, along with their perception of their knowledge in this area, indicates the necessity to improve their didactic and practical training. A further extended survey will be conducted to evaluate the educational experience of residents from all medical specialties that use 3D imaging techniques in neck and head imaging.

THE INFLUENCE OF PREMATURE LOSS OF TEMPORARY UPPER MOLARS ON PERMANENT MOLARS

E. R. Cernei , Dana Cristiana Maxim, Irina Nicoleta Zetu
University of Medicine and Pharmacy "Grigore T. Popa"- Iasi
Faculty of Dental Medicine
Department of Dental Surgery

THE INFLUENCE OF PREMATURE LOSS OF TEMPORARY UPPER MOLARS ON PERMANENT MOLARS(Abstract): **Aim:** Premature loss of primary molars due to dental caries and their complications has been associated with space loss and eruptive difficulties, especially when the loss occurs early. The aim of our study was to determine the impact of premature loss of temporary upper molars upon the longitudinal axis of the first and second upper permanent molar. **Material and Methods:** The study group included 64 patients 6 -9 years old with premature loss of primary molars and a control group of 48 patients with intact temporary teeth. It was evaluated the angle between longitudinal axis of first and second upper permanent molars and occlusal plane. The sofware used is *Easy Dent 4 Viewer*®.The data were analyzed by using the Statistical Package for the Social Sciences (version 20.0; SPSS, Chicago, III). **Results:** It was observed that premature loss of upper second deciduous molars modifies greater the vertical axis of the permanent molars than the premature loss of first upper primary molar. First upper primary molar loss cause an acceleration eruption of first premolar, which will produce a distal inclintion of the both permanent molars. **Conclusions:** The use of space maintainers after premature loss of the second upper temporary molar is a last solution in preventing tridimensional lesions in the dental arch and occlusion. **Keywords:** PREMATURE LOSS, AXIAL MODIFICATION, PERMANENT UPPER MOLARS , DENTAL CARIES, TEMPORARY TEETH.

Premature loss of temporary teeth, as a consequence of untreated dental cavity of temporary teeth, may determine serious tridimensional dental, dento-dental, dento-alveolar, occlusive and variably skeletal disorders. We thus witness a migration of permanent teeth, during intra-maxillary or oral eruption, leading to a dento-alveolar incongruence. Over-eruptions of opposite teeth, narrowed arch formation, reversed toothing, premature contacts and occlusal interferences may also occur (1).

Studies have shown that premature loss of temporary first molars (m1t) mainly determines the distal migration of temporary canines. In this case, the mesial displacement of permanent molars or their mesio version doesn't occur (2). Greater effects appear at the moment of premature loss of temporary second molars, as they serve as a guide for the eruption of the permanent molars (3). The premature loss of temporary secondary molars (m2t) – mainly maxillary – determines a shortening of the arch length due to the mesial migration of permanent molars, thus compromis-

ing the „lee-way space" by affecting the posterior support area (4). The radiologic examination (orthopantomography) is a must in case of these patients, allowing the quantification of the leaning degree of permanent molars.

The main purpose of this study is to assess the impact of the premature loss of temporary upper molars on the longitudinal axis of the permanent molars. Another objective is to see whether there appear significant changes in the eruption sequence of the successor in these conditions.

MATERIAL AND METHODS

The study included 112 orthopantomographies of subjects aged between 6 and 9 who reported to the Pediatric Dental Clinic Iaşi. Out of these, 64 patients showed premature loss of a temporary upper molar and 48 had intact dentition. The condition of the subject selection was that the incisive teeth and permanent molars be intact. All the patients were given specialty treatment and their mandated, informed and motivated assent was obtained.

All orthopantomographies were conducted at a single radiologic center using the *PaX-Uni3D (Vatech)*® radiologic unit. The measurements were made by a single examiner using the *Easy Dent 4 Viewer*® software.

The processing of orthopantomographies included the identification of the following structures (fig. 1):

-*the right/left occlusion plane* – the tangent line to vestibular cuspids of the temporary molars/pre-molars or of lower temporary molars right/left (in case of loss of both temporary upper molars from the same quadrant);

- *the axis of the upper primary first permanent molar (M1)*-line passing through the center of the crown and the center of the radicular bifurcation;

- *the axis of eruption of upper permanent secondary molars (M2)*-the line passing through the middle of the crown and the center of the beginning of radicular bifurcation.

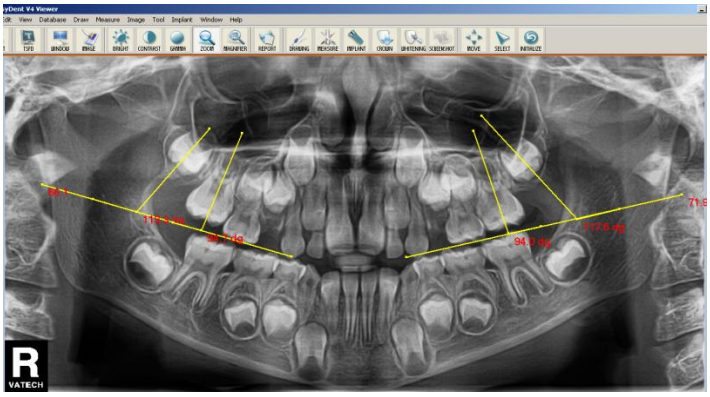

Fig. 1. Orthopantomographic aspect of premature loss of temporary upper molars

By tracing the following benchmarks, we shall evaluate the angle formed by the longitudinal axis of the primary, namely secondary permanent molar and the occlusal plane in the two upper quadrants.

The software used for the data analysis was *SPSS 20.0*. The error margins used in the statistic interpretation are of 5% and the

confidence interval was of 95%. We calculated the frequency parameters and descriptive parameters (average, standard deviation, minimum and maximum value) for each group. We used the t-student test to compare the group with premature loss with the control group. We used the t-pairs test to evaluate the correlation of the M1 upper axis with the M2 upper axis (right/left).

RESULTS

Of the 112 orthopantomographies conducted, 61 (54%) patients were males and 51 (46%) patients female (fig. 2). Concerning the subjects' age distribution, there is a prevalence of patients aged 7 and 8, with a mean age of 7.29 (tab. I).

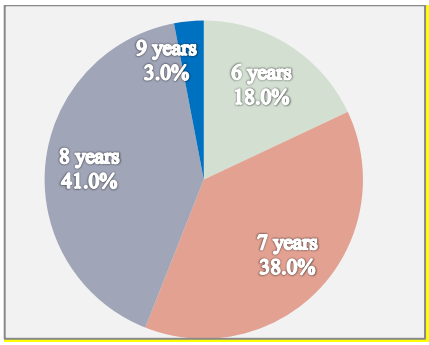

Fig. 2. Group structure on age

TABLE I

Correlative dispersion of patients depending on age and gender

Sex/group	N	Mean	std. error	std. dev	Min	Max
male	**61**	**7.25**	**0.114**	**0.844**	**6**	**9**
premature loss group	35					
control group	26					
female	**51**	**7.33**	**0.11**	**0.739**	**6**	**8**
premature loss group	29					
control group	22					
Total	**112**	**7.29**	**0.08**	**0.795**	**6**	**9**

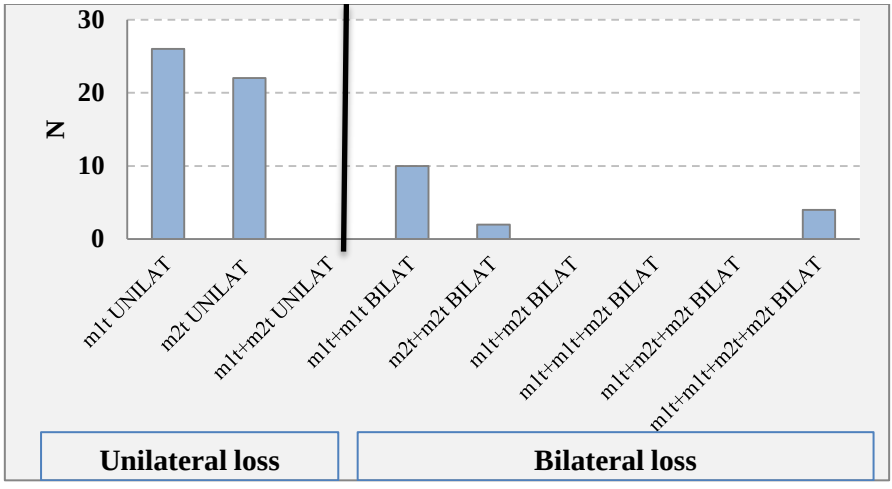

Fig. 3. Losses of m1t, m2t – comparative statistics

In our study, a total of 88 temporary upper molars were prematurely lost due to untreated dental cavity. The cumulated frequency of temporary primary molars is higher (61.36%), as compared to the secondary temporary molars (38.64%). At the same time, the frequency of the bilateral primary temporary molars is rather high, namely of 8.9% of the total cases studied (fig. 3).

From the point of view of angulations, average mesio version of the primary upper permanent molar for the control group is of 92.5° (79-110°), while for the secondary permanent upper molar of 116.5° (90-140°).

The premature unilateral loss of temporary upper molars determines a slight disto version of the primary permanent molar most likely due to the eruption spurt of first premolar (with an angular mean value of 93.9° (variation between 89.3° and 108°) compared to the mean value of the witness group of 92.26° as a compensatory phenomenon. In turn, the loss of temporary second molars has a negative influence through a mesial inclination of permanent molars (mean angular value of 90.18° for M1 and 111.86° for M2) (Fig. 4**).**

Bilateral loss of upper first temporary molars determines a distal compensation of the permanent molars axis (mean angular values of 95.13° for M1 and of 121° for M2). The greatest effect is caused by the bilateral loss of m1t and m2t which determines a strong mesio version of the primary permanent molars (mean angular values of 74.375° compared to the mean value of the witness group, of 92.26°). At the same time, one can notice a reduced influence on the eruption axis of the secondary permanent molar (fig. 5).

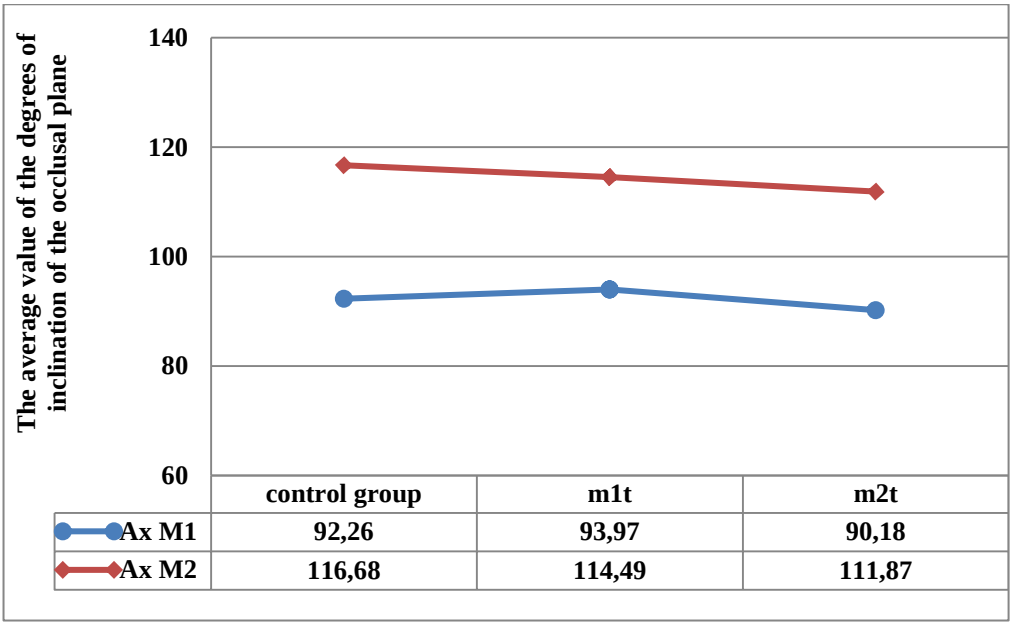

Fig. 4. Influence of unilateral premature loss of temporary upper molars on the inclination of permanent molars

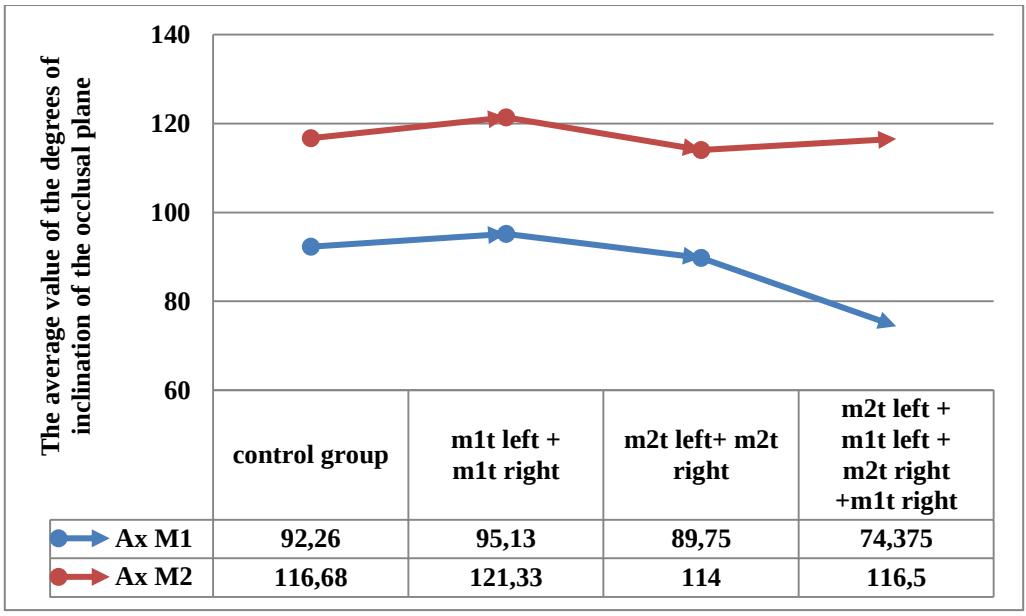

Fig. 5. Influence of bilateral premature loss of temporary upper molars on the inclination of the permanent molars

DISCUSSION

The concept of premature loss was defined as the exfoliation of deciduous teeth on the arch more than 12 months prior to the normal period of permanent teeth eruption (3,4), exceeding the normal variability limits of the exfoliation sequences of temporary teeth.

For both arches the highest space amount lost is due mainly to the mesial inclination of permanent molars. This inclination depends mainly on the dental age during extraction but also on the sequence/periodicity of eruption (5, 6).

The results obtained from the point of view of the frequency of premature loss of temporary molars due to dental cavities are similar to those obtained in other studies (7, 8). For the maxillary arch the premature losses are most frequent and are met in case of the primary temporary molar**,** namely in 61.3% of the total cases under analysis.

Based on the software analysis we could determine with higher accuracy the angle formed by the longitudinal axis of the permanent molars with the occlusion plane. These aspects are relevant under the aspect of the interrelation between the moment of premature loss of temporary molars and the moment of eruption of the primary permanent molar. The context of the premature loss of secondary temporary molar occurred after the initiation of clinical eruption of the primary permanent molar.

In the case of the *loss of the primary maxillary temporary molar* there are numerous contradicting studies. Some authors argue that there occurs a decrease of the postextractional space "within 6 months", especially through the displacement of the temporary canine, but also through a palato version of the permanent incisive teeth (9)**.** *Park et al* using a tridimensional scanning laser method of models conclude that "the

premature loss of the primary temporary maxillary molar, in a I class molar, has a limited influence on the existing space for permanent dentition"(10). *Lin* in a more recent study from 2011, states that after 12 months from the premature extraction of the primary temporary maxillary molar, the space reduction is due only to the distal displacement of the temporary canine. The same author even states that there is an increase of the arch parameter, of the intercanine length and width (2). A Brazilian study conducted by Macena B. et al in 2011 confirms the latest results (5).

The most interesting study was published by Northway in 2000, in which he proves schematically that "at the moment of the premature loss of the primary temporary maxillary molar, the primary premolar start to erupt in a mesio position, as a consequence of the mesial inclination of the temporary secondary molar and thus will consume the space for the permanent canine, which will remain included or will erupt vestibular" (11). Our results are in correlation with the study conducted by Northway, since the loss of maxillary first primary molar would determine a spurt of eruption of the first premolar which will influence the axis of the primary permanent molar by distorting it in compensation, fact proven by the increase of the mean angular value of 93.9^{o} as compared to the mean angular value of the control group, 92.26 ^{o}.

Numerous studies showed that the *premature loss of secondary temporary molars* determines a higher loss of leeway-space than in case of the loss of primary temporary molar, both due to the greater difference of the mesio distal diameter and to the fact that the permanent primary molar and the secondary one losses its contact point and follows the tendency of all teeth to displace mesially or to incline mesially (12, 13). This is also proven by our study through the much lower mean angular values for the permanent maxillary molars in case of premature loss of secondary temporary maxillary molar as compared to the mean angular values of the witness group. Nonetheless, no statistically significant situation was found in any group to influence the axis of the upper molars.

A study carried out by *Leroy R. et al* (14) in 2009 showed that at the moment of cavity affection (cavity, filling, extraction) of both maxillary temporary molars on the same half-quadrant the classic eruption sequence "4-5-3-7" will change to "3-4-5-7" or "4-3-5-7", with an accelerated canine eruption. In our study, the bilateral loss of first temporary molar and second temporary molar only determined an accentuated mesio version of primary permanent molars. The main reason for thus incongruence is the fact that the four patients who lost prematurely the upper temporary molars had a very young age (<5), and the orthopantomography was made at 6 years old. However, one can notice the low influence on the eruption axis of the secondary permanent molar.

CONCLUSIONS

This study highlights one again that the premature loss of temporary molars determines mainly a reduction of the arch length in the molar region. The space shrinking mostly appears through mesial migration and inclination of the molars, through the modification of the inclination of their axis of bone implantation and, to a smaller degree, through the distal migration of the canine.

In addition, the change of the eruption sequence following the premature loss of temporary molars is a phenomenon which

should be considered, especially when an interceptive treatment is adopted, with the preservation within normal limits of the morpho-functional occlusal complex.

DEVELOPMENT OF A MODIFIED-RELEASE PELLETS FORMULATION WITH METOPROLOL TARTRATE AND KINETIC ASPECTS OF *IN VITRO* RELEASE (Abstract): **Aim**. The development of a new pellets formulation which is able to modulate the release of metoprolol tartrate, an active pharmaceutical ingredient very soluble in water and therefore very difficult to process. **Materials and methods**: Two types of different viscosity grade hydroxypropyl methylcellulose (Methocel K100; HPMC 15.000) and Eudragit NE30D are used as prolonged drug release agents, thus resulting in three formulations which have been prepared in form of pellets, in a conventional coating pan. The obtained pellets are characterized and compared in terms of: particles size distribution, drug loading efficiency, drug content and kinetic of *in vitro* drug release. **Results**: Lower amounts of Eudragit NE30D (7.5%) determine more uniform size distributions of particles. Drug content and charging efficiency is higher in case of fractions ranging in size from 0.80 to 1.25 mm. The combination of HPMC 15000 with 10% Eudragit NE30D leads to a prolongation for a period of 11.5 hours of metoprolol tartrate release. Release kinetics analysis was performed by fitting the *in vitro* release profile with different kinetic models. **Conclusions**: It was developed a pellets formulation that release *in vitro* the metoprolol tartrate in an extended mode, with Korsmeyer-Peppas kinetic type. **Keywords:** METOPROLOL TARTRATE, PELLETS, MODIFIED-RELEASE, *IN VITRO* KINETICS

The pellets, which are solid multi-particulates pharmaceutical forms used for oral administration in form of hard gelatin capsules or tablets, might have either an immediate release of the active ingredient or a modified (controlled) release, at different levels of the gastro-intestinal tract (stomach, intestine, colon) (1, 2, 3). During the formulation process of the pellets, the physical - chemical properties of the active substances and the mechanism of release are considered in order to choose the auxiliary ingredients and the adequate coating agents. Also, the formation process is influenced by the way the pellets are prepared. As multi-particulates pharmaceutical

forms, the pellets provide the advantage of a constant behavior during the release process of the active ingredient. Through the association in a pharmaceutical form of some pellet formulations with different profiles of active substance release it can be achieved a higher control of the active ingredient delivery, with a stronger therapeutic efficiency (4, 5, 6).

The purpose of his study was to formulate pellets with metoprolol tartrate as active ingredient. In order to obtain an optimal formulation, which is meant to enable the modulation of the active ingredient release rate, the specifications from the professional literature and previous researches in the same field were considered (6, 7, 8).

The active substance chosen to be elaborated in the form of pellets is metoprol tartrate (MT), a substance from β- blocker class. The MT is a β1 adrenolytic selective lipophilic and light quinidine, being the choice in tachyarrythmias. The antirhythmless action is caused by the negative influence of the five functions of the myocardium: has chronotropic, dromotropic, inotropic and negative tonotrop effect; due to the negative inotropic effect it takes place the decrease in the cardiac charge. It reduces the induced tachycardia of the exercise and stress, and, due to the liver cleansing, the dosage will be reduced in hepatic insufficiency. It has a short half-life (3-4h). It is recommended in HTA angina pectoris for effort, acute myocardial infarct, supraventricular and ventricular tachyarrhythimias (6).

Although this active pharmaceutical ingredient was studies in many experimental research (9, 10, 11, 12), MT still remains an interesting substance from the therapeutical perspective, this being the reason for which it was chosen in the present study. Beside this, it is assessed to establish the release mechanism of the active ingredient, which contributes to the development of a formula with maxim efficiency.

MATERIAL AND METHODS

Material

Metoprolol tartrate (Moehs Ibérica SL, Spain), sugar nonpareils 0.5-0.6 mm (Alcom SA, Romania), Kollidon K 25 (Merck, Germany), Aerosil 200 (S&D Chemicals, U.K.), talcum (S&D Chemicals, U.K.), hydroxypropyl methylcellulose Methocel K100, HPMC 15.000 (Merck, Germany), Eudragit NE30D (Degussa, Germany). All the reagents used were of analytical grade.

Methods

Pellets preparations.

Pellets were prepared in coating pan (Erveka, Germany), by powdering layers of poweder which contain metoprolol tartrate (as active ingredient) on sugar nonpareils (as inactive cores). In composition of pellets three prolonged drug release agents were used: two sorts of hydroxypropyl methylcellulose that differ in viscosity (Methocel K100, HPMC 15.000) in form of powders in the coating powder layers and a neutral copolymer based on ethyl acrylate and methyl methacrylate in form of an aqueous dispersion (Eudragit NE30D) used as binder agent too. According to the data presented in table I and II, three type of pellets has been obtained: formulation A, B and C, respectively.

Pellets size distribution: The pellets (30 g) were sieved (18 min) using a set of sieves with different apertures (2.50, 1.25, 0.80, 0.50 mm) placed into a sieve shaker equipment system. Each weight fraction was recorded (13).

TABLE I

Composition of metoprolol tartrate pellets

Ingredients / Code of formulation	Quantity (%)		
	A	B	C
Sugar nonpareils:	**33.33**		
Powder for layering:	**59.17**		
Metoprolol tartrate	26.00		
Aerosil	0.50		
Talcum	1.00		
Kollidon K25	2.00		
Methocel K100	29.67	28.17	-
HPMC 15.000	-	-	28.17
Binder aqueous dispersion:	7.5	10	10
Eudragit NE30D (dry substance)	(2.25)	(3.00)	(3.0)

TABLE II

Layering condition for pellets preparation in coating pan

	33
Charg load with powder for layering (g)	67
Binder spray rate (g/min)	0.2-0.3
Pan speed (rpm)	35
Inclination angle pan (°)	40
Binder spray time (min)	140
Drying in pan after layering (min)	15
Drying in an oven	24 h (40˚C)

Evaluation of pellets metoprolol tartrate content: Metoprolol tartrate charged in pellets (the actual content) was calculated using the following formula:

$$I\ (\%) = \frac{Q_{(g)}}{m_{(g)}} \cdot 100$$

where, *I* is the amount of MT (actual contents), *Q* is the amount of MT used in formulation (theoretical expected content) and *m* is the mass of pellets that contains 100 mg MT (experimental data determined by a spectrophotometrically official method).

$$E\% = \frac{Q_p\ (g)}{Q_t\ (g)} \times 100$$

where, *E* is efficiency of charging of pellets with MT (loading efficiency), *Qp* is the amount of MT determined in pellets (actual content) and *Qt* is the amount of MT used in formulation (theoretical expected content) (14,15).

In vitro release of metoprolol from pellets

The Erweka apparatus was used for this test buffer phosphate solution (pH= 6.8) as media, at 37±0.2˚C. The quantity of tested pellets was considered such as to correspond with 100 mg MT (16).

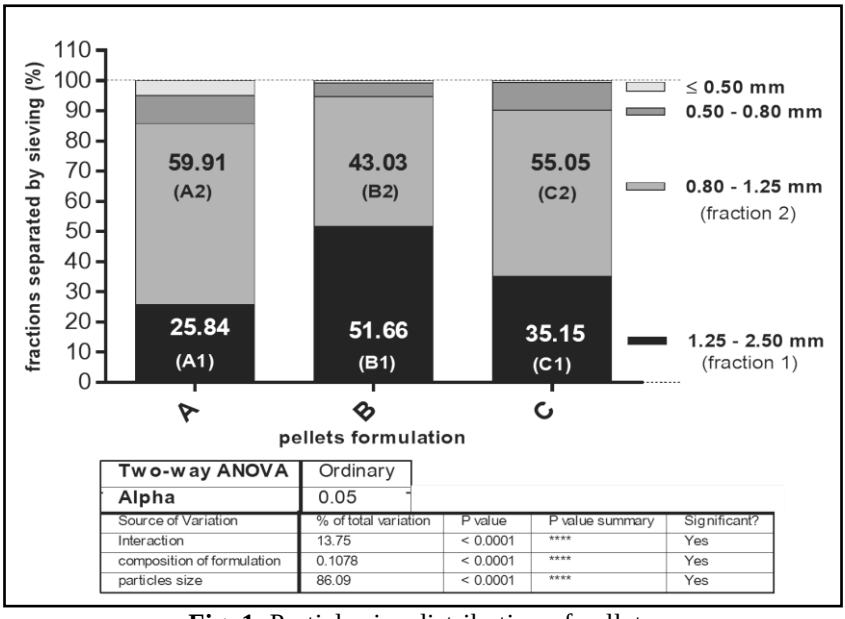
Kinetic of metoprolol release from pellets: The DDSolver software was used for fitting the data and for calculation of the statistical parameters required for comparing the dissolution profiles (17).

RESULTS

Particles size distribution

Particle size evaluation of pellets by sieving method allowed separation of two main fractions for each of the three prepared formulations (A, B and C): fraction "**1**"- consists of pellets with diameters of 1.25 to 2.50 mm and fraction "**2**"- pellets with diameters ranging from 0.80 to 1.25 mm, respectively. Variations of particle size distributions (fig. 1) are caused by the compositional differences of pellets.

In terms of pellets size distribution, it is found that more than half of the pellets of formulation A (prepared with Methocel K100 and 7.5% Eudragit NE30D) have small dimensions, fraction "**1**" (A1- 59.91%; 0.80-1.25 mm) accounting for twice of fraction "**2**" (A2- 25.84%; 1.25-2.50 mm). Size distribution of pellets in formulation B (prepared with Methocel K100 and 10% Eudragit NE30D) indicates that a small additional amount of Eudragit NE30D (2.5%) determines a significantly increasing in the size of pellets (B1- 51.66% vs. B2- 42.03%). This effect does not appear in case of formulation C (prepared with HPMC 15.000 and 10% Eudragit NE30D). Based on this last observation, the use of HPMC 15.000 in association with 10% Eudragit NE30D (C1- 35.15%/C2- 55.05%) could be more advantageous when obtaining small pellets is desired.



Two-way ANOVA	Ordinary			
Alpha	0.05			
Source of Variation	% of total variation	P value	P value summary	Significant?
Interaction	13.75	< 0.0001	****	Yes
composition of formulation	0.1078	< 0.0001	****	Yes
particles size	86.09	< 0.0001	****	Yes

Fig. 1. Particle size distribution of pellets
and statistical analysis of interaction between variables

Evaluation of pellets metoprolol tartrate content

Actual drug content (experimental data) and loading efficiency (calculated on the bases on theoretical expected data) are two parameters dependent on the size of the pellets. Data presented in table III show that the pellets contain metoprolol tartrate in range of 20% to 25%, with small differences between pellets formulations.

TABLE III

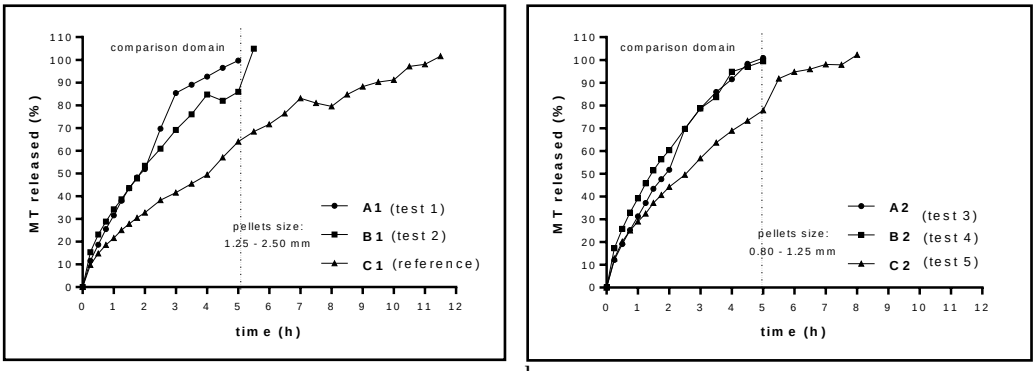
Results of evaluation of pellets metoprolol tartrate content

Formulation		Actual active content MT (%) ± SD (*n= 3)	Loading efficiency MT (%) ± SD (*n= 3)
A	**1**	19.81 ± 0.30	75.32 ± 0.67
	2	21.30 ± 0.60	82.22 ± 0.79
B	**1**	22.13 ± 0.56	86.23 ± 0.54
	2	23.85 ± 0.55	94.51 ± 0.50
C	**1**	20.38 ± 0.58	79.62 ± 0.76
	2	24.92 ± 0.65	97.14 ± 0.66
*n= number of experimental determinations			

However, in case of all three formulations, it can be noticed a higher efficiency in charging for fractions "2" (small particles: 80-97%) comparatively with fractions "1" (large particles: 75-86%). This might be due to the larger exposed surface area of the small particles in the powder layering process through which the construction of pellets occurs.

In vitro release of metoprolol from pellets

Dissolution study was performed both from the fraction "**1**" and fraction "**2**" of each pellets formulation (A, B and C). As a result, six dissolution profiles were determined by plotting the experimental data (fig. 2).



a b

Fig. 2. Release profiles of metoprolol from pellets, grouped by size (fraction "**1**"-a *vs.* fraction "**2**"-b)

The results reveal, both for fraction "**1**" and fraction "**2**", that formulations A (Eudragit NE 2.25%) and B (Eudragit NE 3.00%), based on Methocel K100, release the initial active content (100% approximately) within 5 hours, which means that there are no significant differences of the metoprolol release rates. In case of formulation C, using another combination of drug release retarding agents (HPMC 15.000, Eudragit NE 3.00%), metoprolol is released more prolonged than from the others two

formulations (8 h-C2; 11.5 h-C1). Considering C1 as reference and the others as test formulations, when comparing the release profiles for the first 5 hours of the dissolution test in terms of differences (f1) or similarity (f2), it appears that the C1 release profile is different than the others (fig. 3).

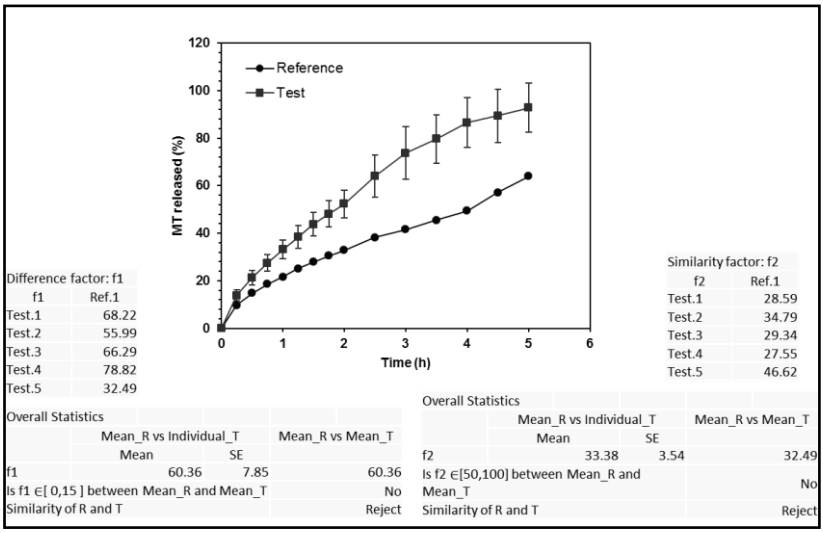


Fig. 3. Statistical comparison of metoprolol release profiles from pellets

Kinetic of metoprolol release from modified-release pellets

In order to determine the mechanism of metoprolol release kinetic from modified-release pellets, C1 release profile was fitted with various mathematical equations. Based on the values of adjusted coefficient of determination (Rsqr_adj), it was revealed that release of metoprolol occurs by dissolution and diffusion, according to Korsmeyer-Peppas equation (fig. 4).

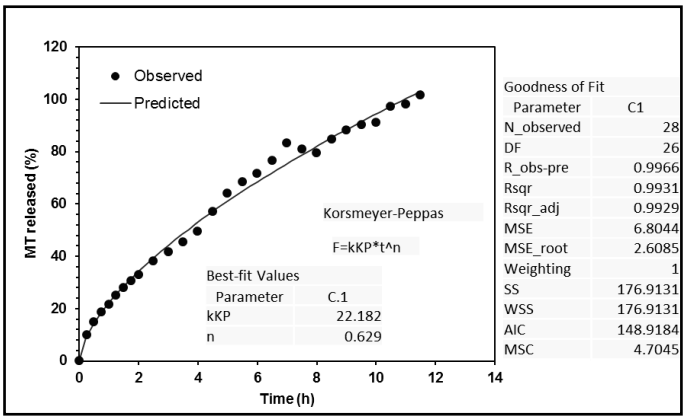

Fig. 4. Kinetic parameters calculated for release of metoprolol from C1 (Modified-release pellets)

CONCLUSIONS

The particles size distribution of pellets obtained by powder layering in coating pan method revealed the direct influence of formulation variables on the amounts of factions separated by sieving method. It has been also found that size distribution of pellets is consistent both with the metoprolol tartrate loading efficiency and the release of this active ingredient from pellets.

Although all six studied formulations of pellets showed a prolonged release of metoprolol, it seems that only formulation C1 (prepared with HPMC 15.000 and 10% Eudragit NE30D as combination of agents that modify the release) managed to prolong the release process to about 11 hours. Mechanism of kinetic release is based on dissolution and diffusion processes, according to Korsmeyer-Peppas model.

CLINICAL-EPIDEMIOLOGICAL TRENDS OF HERPES ZOSTER: A 5-YEAR STUDY (Abstract): Herpes zoster (shingles) is a neurocutaneous viral disease, in recent years its incidence increasing throughout the world. **Aim**: To study the incidence of herpes zoster among Iasi county patients requiring hospital admission and to analyze the clinical and epidemiological features and socioeconomic status of the study group. **Material and methods**: Retrospective study of 158 patients admitted to the largest clinical dermatology department in North-eastern Romania, the Clinical Dermatology Department of the Iasi "Sf. Spiridon" University Emergency Hospital. The study was conducted over a period of five years and included the analysis of epidemiological data, socioeconomic status, clinical forms of disease, associated diseases, pathology reports for skin biopsy fragments, administered treatment, and disease course. **Results:** This study confirms that shingles is not a sex-specific disease, the female/male ratio being 1.22: 1. Most patients belonged to the age group 70-80 years, accounting for about 35% of all patients, followed by the age group 60-70 years (24.6% of cases). A slight increase in the number of cases was recorded in autumn and summer in patients living in rural areas. 1.3% of the cases were diagnosed both with the disseminated form of disease, and complications (eczematization, bacterial superinfection, skin necrosis). 7.6% of patients presented additional skin disorders (pityriasis versicolor, impetigo, psoriasis vulgaris, mucocutaneous candidiasis), which raised the suspicion of an immune deficiency predisposing to shingles. The absence or late initiation of specific antiviral therapy correlated with prolonged hospital stay up to 4-6 days. We found an association between the erythematous form of shingles and young age, while the hemorrhagic or necrotic forms were present in the elderly and/or ill patients. The course was favorable and the length of illness was significantly shortened when the treatment adequate to the clinical form was administered. Associated comorbidities (essential hypertension 38.6%, dyslipidemia 24.6%, diabetes, mellitus 9.49%, chronic venous disease, other skin diseases) represent a factor complicating the development of herpes zoster by the cumulative stress the body is exposed to. **Conclusions:** The main statistically significant epidemiological data in the study group are: older age (over 60 years), associated diseases (which by the marked imbalances induced in the body increase the risk of varicella zoster virus reactivation) intense psychological stress. The following parameters did not change the risk of developing shingles: area of origin, sex, the season at disease onset, number of hospital days, and administered treatment. Early diagnosis and treatment of this disease is important for maintaining a good quality of life, to avoid complications, to limit the extent of the disease and its transmission to others. **Keywords**: HERPES ZOSTER, VARICELLA, IMMUNOSUPPRESSION.

Herpes zoster (shingles) is a neurocutaneous viral disease, being an acute viral infection of the skin caused by the reactivation of varicella zoster virus that has remained latent within the dorsal root and cranial nerve ganglia (1). Shingles often manifests decades after the primary infection (chickenpox), and occurs by virus reactivation and its spread to other mucosal skin surfaces through centrifugal migration. The factors triggering the reactivation of the dormant virus are not exactly known, but it is believed that reexposure to the virus, acute or chronic infectious diseases, neoplastic processes, some medications, and emotional stress play an important role. Immunocompromise increases the risk of virus reactivation, meaning that the incidence of shingles increases with aging and immunosuppression (2).

The incidence of shingles is of approximately 3.4‰ per year in the general population, increasing to 11.8‰ per year in the population over 85 years. In recent years, the frequency of this viral manifestation is increasing; it is a true public health concern since a good quality of life, avoidance of severe complications and limiting disease extension and its spread to other family members or entourage depend on early diagnosis and correct treatment of this disease (3).

The disease occurs sporadically throughout the year in all races and affects both sexes equally (6). The incidence is low in the early years of life, except for young people diagnosed with AIDS, lymphoma or other malignancies, and after bone marrow transplantation. Less than 10% of shingles patients are younger than 20 years and only 5% younger than 15 years (4, 7).

In the general population, the incidence rate is 10-20%, but increase to 50% in those who reach age 85 (8). After FDA approved the herpes zoster vaccine in 2006, a study of 38,000 adults aged over 60 years showed a decrease in the incidence of herpes zoster by 51.5% (2, 5).

The studies conducted in Romania show a sudden increase in the number of shingles cases in children aged 10-12 years (9, 10).

The aim of this study was to investigate the herpes zoster cases recorded over a 5-year period from epidemiological, clinical, therapeutic and socioeconomic status point of view.

MATERIAL AND METHODS

This study is a retrospective analysis of all cases diagnosed with herpes zoster at the Dermatology Department of "Sf. Spiridon" University Emergency Hospital during 2008-2013. The study group included 158 patients, 71 males and 87 females, aged 9 to 92 years. The medical records, patient photographs, and the histopathology reports for skin biopsy fragments were used. Epidemiological data, such as age, sex, area of origin, socioeconomic status, time of year when the disease occurred, and data related to the clinical form of herpes zoster, associated diseases, pathology reports, administered treatment and disease course were also reviewed.

RESULTS

Of all patients admitted in the interval 2008-2013 we selected a group of 158 patients with either typical signs and symptoms of various forms of herpes zoster (fig. 1) or with a totally atypical clinical picture.

Most patients presented a form of herpes zoster accompanied by neurological symptoms (56.3%). Of all patients, 29.1% developed a typical simple herpes zoster, and 1.3% were diagnosed with disseminated herpes zoster and complications (eczematiza-

tion, bacterial superinfection, skin necrosis).

Ophthalmic herpes zoster was diagnosed in 12% of cases, half of them complicated by herpetic keratitis or uveitis (fig. 2).

Fig. 1. Herpes zoster in the left intercostal zone

Fig. 2. Herpes zoster ophthalmicus

This study confirms that shingles is not a sex-specific disease. The statistical analysis of this study group showed that the balance is slightly tilted towards females (87 vs. 71), female/male ratio 1.22: 1.

By calculating patient age at the time of herpes zoster diagnosis, we found that most patients belonged to age group 70-80 years, accounting for approximately 35% of patients, followed by age group 60-70 years (24.6%) (fig. 3).

Of the 3% of patients under 20 years of age, a group of children aged 10-12 years, living in urban areas, without organ abnormalities or laboratory documented immunosuppression, but under severe mental stress, as declared by them and their parents, due to intense preparation for the 5th grade entrance exam stood out (fig. 4).

Although shingles occurs sporadically throughout the year, a slight increase in the number of cases in the autumn and summer compared to other seasons was noticed. This can be explained by the direct effect on health of weather variations, especially in the case of an elderly patient, with weakened immune system, living in a rural area where physical work is more intense during summer and autumn.

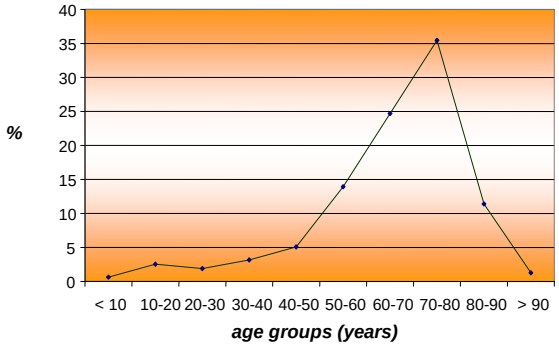

Fig. 3. Age distribution of the study group

Fig. 4. Lumbosciatic herpes zoster (L3), left side

In our study group there was a slight predominance of shingles patients coming from rural areas (53%) compared to urban areas (47% of cases).

Immunocompromised patients have a 20-100 fold higher risk of developing herpes zoster compared to the immunocompetent patients of the same age. In the study group and 7.6% of the patients also presented other skin problems (pityriasis versicolor, impetigo, psoriasis vulgaris, mucocutaneous Candida infections), which raised the suspicion of an immune deficiency predisposing to shingles.

Associated diseases are an additional stress to the body, thus making it vulnerable to reactivation of varicella zoster virus. In our study group, the most common associated disease was essential hypertension (38.6%), followed by dyslipidemia (24.6%) and diabetes mellitus (9.49%).

The average duration of herpes zoster was 10-15 days, but it took as long as a month before the skin cleared completely. In our study group hospital stay ranged between 2 and 18 days, depending on patient status upon admission, associated diseases and course under treatment (fig. 5).

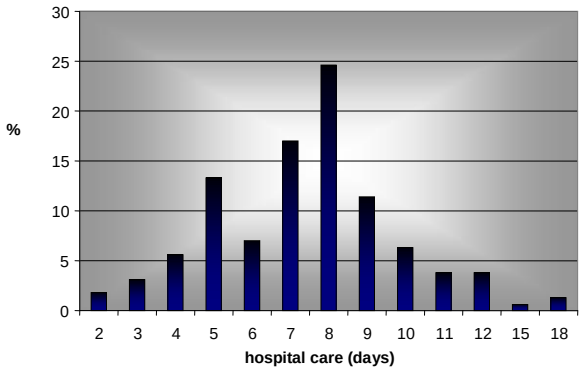

Fig. 5. Length of stay distribution of the study group

The administered treatment had an overwhelming influence on disease progression, but of great importance was the time of treatment initiation from the onset of symptoms. 83.5% of patients received full topical and systemic treatment (antiviral, antiinflammatory, analgesic, group B vitamins, ± antibiotics), but some patients

(16.5%) received no etiological treatment. Absence or late initiation of specific antiviral therapy may be correlated with prolonged hospital stay; our patients were hospitalized for a period ranging from 6 to 18 days, average 12.3 days. At the opposite pole were the patients treated correctly and on time, who were hospitalized for 2 to 12 days, average 8.1 days.

Skin biopsy followed by histopathology of skin fragments were necessary in only 3 cases for making a positive diagnosis of certainty: 1) an oligosymptomatic case with only 2-3 clusters of blisters on the dorsal and lateral external aspect of the right hand, with multiple relapses over the last 3 years (at 3-4 month intervals) that had to be differentiated from zosteriform herpes; 2) a case of eczematized shingles with atypical appearance, clusters of blisters on a poorly-defined erythematous plaque, with irregular, crumbling margins; 3) a case presenting blisters erupting in clusters, on an erythematous base, disseminated, accompanied by discrete symptoms in a young immunocompetent patients without any other disorders.

The study group included patients aged 9 to 92 years. Retrospectively, we found an association between the erythematous form of shingles herpes and young immunocompetent patients. Other associations were found between the hemorrhagic form and elderly and ill patients and between elderly ill or immunocompromised patients and necrotic shingles.

Under optimal treatment (started on time and correctly conducted) the occurrence of new clinical elements was prevented, with healing without sequels in some cases and acromial and atrophic scars in other cases. In our study group, 97.47% were discharged "improved", 2.53% "cured", none “stationary” or “deceased”.

DISCUSSION

Age distribution of the patients in our study group is similar to data reported in Europe, being slightly deflected to the right, as most patients were over 60 years of age.

Also, there was a statically insignificant predominance of female patients (55% vs. 45%). Rural/urban distribution of cases was balanced, with a slight increase in the number of rural cases (53%).

Given the limitations of a retrospective study, we can conclude that the associated diseases (essential hypertension 38.6%, dyslipidemia 24.6%, diabetes mellitus 9.49%, chronic venous disease, other skin diseases) are a factor complicating the course of herpes zoster, by the cumulative stress the body is exposed to.

Most cases of herpes zoster were accompanied by neurological symptoms (56.3%), followed by the simple classical form (29.1%) and ocular shingles (12%).

Also, an association between herpes zoster erythematous form and young patients was noted. Hemorrhagic and necrotic forms were present in the elderly and ill patients.

CONCLUSIONS

The main statistically significant epidemiological data related to herpes zoster in the study group are: older age (over 60 years), associated diseases (which by the marked imbalances induced in the body increase the risk of varicella zoster virus reactivation), and intense psychological stress. No significant change in the risk of developing shingles was found in relation with the following parameters: area of origin, sex, season at disease onset, length of hospital stay, and administered treatment.

Herpes zoster is a disease that was ig-

nored by patients for hours or days after its onset or was incorrectly diagnosed in the prodromal stage, pain preceding the appearance of skin lesions. Early diagnosis and immediate initiation of specific antiviral therapy are essential for a good quality of life and for avoiding the complications and limiting the extent of disease and its transmission to others. To this end, we suggest a thorough history and physical treatment is preventing post herpetic neuralgia. Additional diagnostic tests such as skin lesion biopsy and histopathology or PCR may be useful in atypical cases.

THE IMPORTANCE OF CONTROL ELEMENTS IN DENTAL OFFICE MANAGEMENT

I. C. Lupu

Discipline Public Health and Oral-Dental Management

THE IMPORTANCE OF CONTROL ELEMENTS IN DENTAL OFFICE MANAGEMENT (Abstract): In the current economic situation statistical indicators suggest a decline in global and national dental services market under increased competition. Hence, a cost-effective and strengthening market position. Thus it is recommended the office management to focus on retention and follow active patients and to create a system of quality control maneuvers. In order to achieve these objectives we must monitor certain elements of medical control, economic, management and promotion. **Keywords**: MARKETING SERVICES, CONTROL ELEMENTS, DENTAL PRACTICE, MANAGEMENT

Dental services market evolution can be interpreted using data from private health insurance companies and national professional associations of dentists and the data provided by the companies producing equipment and dental materials (1, 3, 4).

The declared values of dental materials and equipment manufacturers worldwide and European related volumes sold in each category in the last two years suggest a decrease (3, 4). The only categories where positive developments are expressed are *Cad-Cam* technology for radiology equipment and implants, but national companies distributing equipment and dental materials suggest a decline in sales while suspending contracts with C.N.A.S..

All these suggests a decrease in the number of dental treatments at national level made in a dental market with a growing number of dentists and a decrease in addressability to dental care.

In the current market of oro-dental health services proper management may facilitate praxis to new purchases and performing dentist can support multiple roles of professional, manager and entrepreneur.

For the practitioner to effectively control cabinet work certain economic elements must be taken into account, medical, marketing and management. Thus the number of patients is important in the medical act for time allocation, the scheduling, the financial aspect of the revenue they bring human resources in terms of number and their training.

The elements of medical nature are represented by the volume of patients and the number of maneuvers performed, their addressability for certain types of treatment and the quality of care.

Service quality can be measured by the implementation of therapeutic protocols and laboratory checks: X-rays, documenta-

tion patterns, general photos and intraoral camera that can capture intermediate stages, all these also covering the legal aspect of the treatment. Systematizing therapeutic measures will lead to a better control of the quality and increase the success rate. It will also lead to an efficient and predictable use of the time allocated to a particular maneuver, the necessary material and human resources involved. It is therefore recommended the formation of a constant, empathic dentist - nurse team, thus eliminating the syncope in the operating time. It is also recommended that for special, complex cases, to discuss with colleagues from the clinic or other specialists. To perfect the medical act and prevent potential complications it is recommended a review of the patients for the next day. Most people, especially the working population, one that caters to premium service want a more accurate assessment of time spent in treatment in general, and the number of each meeting. To predict this, a very accurate diagnosis should be taken into account, along with its understanding by the patient, both medically and financially. Other items which affect treatment duration are the training of the physician, the medical team, the material equipment of the cabinet and the execution time for laboratory work. Thus the office should be represented by a team of professionals with a flexible work schedule, with an adequate radiology equipment (which saves the patient trip to the radiology lab) to work with a lab, with a reasonable time of performance, which will ensure prompt shipment and provide active assistance (staff offices delegate relationship with patients to determine the color of any adjustments).

Another way to check the quality of medical care is represented by patients' opinions at the end of treatment. Their satisfaction is related to aesthetics, the time spent with them, the attention they enjoyed, all reported to the final estimate.

Patient feed-back related to the therapeutic act and the relationship with the doctor can be obtained using a questionnaire or in a phone conversation at the end of the treatment.

Patient's questionnaire should include questions about patient satisfaction, the presentation of therapeutic solution, and the relationship with the medical team. The answer may be free or quantitative, for example from 1 to 5 or from unsatisfactory to better than expected (5). There should be a section dedicated to suggestions for improving the services indicated in terms of networking, quality and types of treatment.

Patients need for certain services suggests the type of maneuvers that should be provided and hence *the tariffs* (5, 6, 7). Patients' expectations consequently dictate the level of equipment and materials supplied and also the HR element through training and number. *The qualitative* aspect is given by the professional education: specialist surgeon, orthodontist, endodontist, periodontist and *one quantitatively* reflected by the number of doctors, nurses, a receptionist, an accountant and maybe a manager. An increased quality can be achieved by continuous training of doctors and nurses and increasing communication skills within and between the medical team and the patient. This can be done by creating predictive systems, communication patterns, with answers and clear attitude that predict any case linked to the interaction of the patients, with the laboratory, suppliers. These skills can be provided in the job description and must be properly understood and acknowledged by all em-

ployees including participation in training sessions (communication and sales service) organized within the cabinet. Job descriptions should clearly state the professional obligations, continuous improvement skills, achieving periodical goals, including payment of wages, bonuses, professional advancement. Organizing regular meetings with team members will help achieve the objectives by taking certain correctional measures. Also, attention will be given to the relationship with the patients to remind them of periodic monitoring, and for any feedback.

Economic elements are represented by the value of revenue, expense, profit, cash flow. They need to be regularly assessed against monthly, quarterly, annually. Hence the recommendation to delegate tasks to specialized assistance of an accountant and manager.

Cash flow is the financial element that shows all aspects of financial activity is useful in assessing the economic performance of praxis, thus ensuring correct identification of the costs including those represented by insurance, rents, loans, rates, utilities, various contracts with certain companies (the maintenance of equipment, work safety, advertising, security) of various fees (telephone, internet, magazines, subscriptions), equipment amortization, the value of wages. Variable expenses can be represented by the stocking, bonuses, and possible unexpected expenses. To these are added investments in equipment and materials, improvement of human resources, the modernization of space, etc. in relation to inflation, changes in taxes applicable to company and employees and the purchasing power of patients.

Forecasting future investment in new technologies and the improvement of human resources is based on the addressability of patients for certain maneuvers. Acquisition of new technology can be represented by equipment, instruments, new materials, which involve improving human resources for their effective operation. These may include purchase of a radiological device, a dental microscope, a *Cad-Cam* system and an advanced system for composite materials. It can also be represented by the purchase of computer software, a camera with macro lens, to better capture the original situation, the end result, and the characteristics of the teeth and of course related software, which are intended to improve communication between practitioner and patient, between the cabinet and laboratory favoring the medical control.

Predictability of costs involved in performing maneuvers, of control over the time allotted, the addressability of patients determines the most accurate price for the treatment.

Office revenues are the revenues from patients, along with C.N.A.S. contracted amounts for physicians and laboratory examinations. A special category of income can come from contracts with private health insurance companies. A constant minimum flow of revenue can be assured by a predictable schedule of appointments, control and patient satisfaction.

Marketing elements have a role in promoting office services, both existing and new, in selling them and keeping contact with patients; advertizing can be done through the website, business cards, brochures, newsletters promotional campaigns, subscriptions.

Management involves the integration, synthesis, implementation and control of the elements mentioned above. It also in-

volves creating a business plan and implementing it. Business development will determine a delegation of a manager to closely monitor the business parameters. So, the doctor will be able focus on the role of professional and entrepreneur. This is because the national dental services market is still suffering from a lack of training and successful business models. This leads to hesitant evolving and expanding of offices and in purchasing new equipment and technologies.

The manager has to identify the elements that can measure clinical and financial development that, together with the patients determines the office politics.

A performance management involves implementing protocols, predictable system of networking and communication.

They must provide control elements, easy and accurate forecasting (8, 9). Planning and delegation processes involving office work should enable the physician to focus on the professional aspect.

EFFECTS OF PERFLUOROCARBON EMULSION IN RHEOLOGY

Diana Lăcătuşu, Mihaela Baican, Florina Crivoi
University of Medicine and Pharmacy "Grigore T. Popa" - Iaşi

Discipline of Pharmaceutical Physical

EFFECTS OF PERFLUOROCARBON EMULSION IN RHEOLOGY (Abstract): **Aim**: To study effects of a perfluorocarbon emulsion on plasma and whole human blood viscosity in the presence of albumin or modified fluid gelatin. **Material and methods:** We investigated the effects of several PFC concentrations on plasma and whole blood viscosity in the presence of human albumin solution (HAS) or modified fluid gelatine (MFG; Gelofusine) to obtain three PFC emulsion concentrations (4, 8 and 15 g/dL). Three hematocrit levels (Hct) were investigated: 30, 20 and 13%, corresponding to different clinical situations. Plasma and whole blood viscosity was measured at 37°C, using a Couette viscometer for shear rates ranging from 0.2 to128 s^{-1}. **Results and discussion:** All PFC concentrations increased plasma and whole blood viscosity for the same Hct. Viscosity values similar to physiological ones were observed at Hct 13%, with MFG – PFC 4, 8 g/dL and HAS – PFC 15g/dL; at Hct 20%, with MFG – PFC 4g/dL and HAS - PFC 15g/dL; at Hct 30%, and HAS – PFC 4, 8 g/dL. **Conclusions:** We conclude that this PFC emulsion increases plasma and blood viscosity and that among the three studied volume expanders, the interaction with MFG can result in viscosity values above the physiological one even at low Hct values. Our results suggest that such increased blood viscosity could decrease skeletal muscle oxygen pressure. **Keywords:** PFC EMULSION, WHOLE HUMAN BLOOD, VISCOSITY, HEMATOCRIT.

Severe acute blood loss resulting in hemorrhagic shock (HS) can lead to severe tissue damage responsible for high morbidity and mortality (1). The recovery of physiological macrohemodynamics parameters such as arterial pressure and cardiac output, as well as the fast restoration of microvascular perfusion and oxygen supply to vital organs, are the major aims of primary therapy of HS. Intravenous volume replacement with an acellular fluid may restore cardiac output but fails to promote microvascular perfusion (2). Severe hemodilution, due to massive infusions of volume expanders, may further impair tissue oxygenation because of decreased oxygen transport. Survival from shock is directly dependent on the restitution of adequate blood oxygen carrying capacity once the hematocrit (Hct) falls below a critical range of 20-25% (3).

It has been shown that stored as opposed to fresh RBCs have a decreased capacity to deliver oxygen in the microcirculation.

Artificial oxygen carriers based on PFC emulsions have been developed because they can increase oxygen transport in the initial stages of resuscitation (4). Indeed, in the case of acute severe anemia, or acute

normovolemic hemodilution (ANH), these artificial oxygen carriers can increase the oxygen carrying capacity of hemodiluted fluid. PFCs are chemically and biologically inert synthetic compounds (perfluorinated hydrocarbon compounds). PFCs have high oxygen solubility through weak van der Waals forces (4).

The rheological properties of blood regulate many physiological and pathophysiological parameters of the cardiovascular system, such as arterial blood pressure, blood flow in the microcirculation, hemostasis, inflammation, etc. Viscosity contributes to endothelial shear stress (5, 6).

The interactions among PFC and the different volume expanders used in clinical practice have not been studied.

We made the hypotheses that the PFC emulsion interacts with the three above-cited types of colloids and that these interactions modify plasma and blood viscosity; the interactions depend on the value of Hct.

MATERIAL AND METHODS

Human whole blood was diluted with the PFC emulsion mixed with different volume expenders. Three PFC concentrations were tested: 4, 8 and 15 g/dL each combined with Hct values of 13, 20 and 30%. Controls used were human whole blood at 40% Hct and diluted with autologous plasma or the volume expenders at Hct 13, 20 and 30%.

The volume expenders used were: human albumin solution 20% (HAS) diluted in Ringer solution at 50 g/L; gelofusine 4%: a modified fluid gelatin (MFG).

The viscosity of plasma, PFC and volume expanders was measured at 37°C with an automatic capillary viscometer, and expressed in $mPa.s^{-1}$. The viscosity of the different compounds: plasma, volume expanders and whole blood at different Hct levels and of mixtures of each compound with PFC at different concentrations, was determined at 37°C, using a Couette type coaxial viscometer at shear rates from 0.2 to 128 sec^{-1} and expressed in $mPa.s^{-1}$.

RESULTS

The intrinsic viscosities of volume expanders alone or mixed with plasma, in the absence or presence of increasing concentrations of PFC are presented in table I. Volume expanders alone (or in the presence of plasma) exhibit an inverse linear viscosity as a function of shear rate (lower shear rate values are associated with higher viscosity). When PFC emulsion was added, the viscosity increased as a function of the PFC concentration. The intrinsic viscosity was similar between plasma and HAS, but increased strongly with MFG (tab. I).

In preliminary experiments we verified that the presence of the PFC emulsion, even at high concentrations, did not interfere with the measurements of viscosity.

A total of 45 situations, according to Hct values (40, 30, 20 and 13%), volume expanders (plasma, MFG, HAS) and PFC concentrations (0, 4, 8, and 15 g/dL) have been studied. The control situations of whole blood at Hct values of 40%, and blood diluted with autologous plasma and with volume expenders, at Hct values of 30, 20 and 13% respectively were represented in figure 1.

When blood was mixed only with volume expanders (fig. 1), whatever the final Hct, the hemodiluted blood presented always viscosities lower than whole blood at 40% Hct. In the situation where Hct value was 13%, whatever the volume expander used, the viscosity values were similar with those observed upon dilution with autolo-

gous plasma.

When PFC was added to blood hemodiluted with the volume expanders, the viscosity was statistically higher. In fact, the presence of the PFC emulsion, independently of the Hct values, always resulted in highly increased blood viscosity (fig. 2, 3).

TABLE I

Intrinsic viscosity of the human plasma, volume expenders and mixtures of volume expenders with different PFC emulsion concentrations

Solutions	PFC emulsion (g/dL)	Intrinsic viscosity (mPa.s^{-1}) at shear rates 20.4 s^{-1} (left), 128 s^{-1} (right)	
		Alone	Plus plasma
Human plasma	0	1.4	
HAS	0	1.0/1.0	
	4	1.1/1.2	1.0/1.2
	8	1.7/1.5	1.2/1.3
	15	3.0/2.8	5.2/3.1
MFG	0	1.7/1.7	
	4	2.5/2.3	1.8/1.6
	8	3.9/2.9	3.4/2.6
	15	58/off limit	20/9

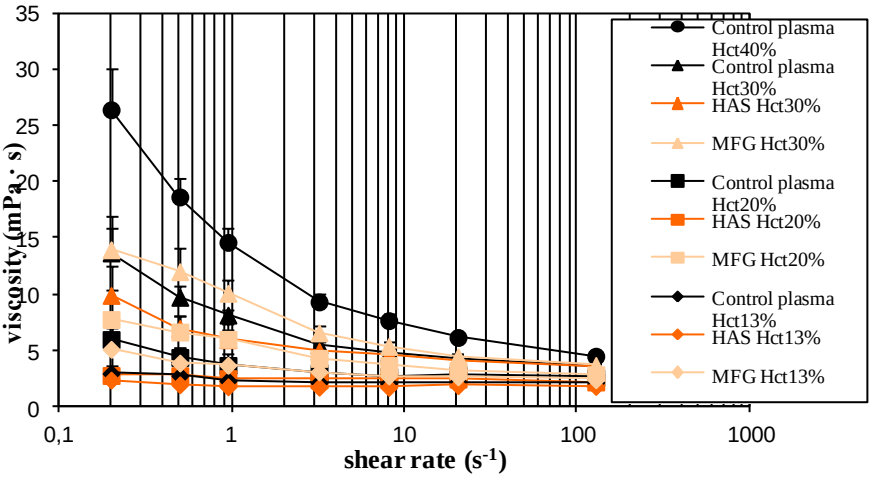

Fig. 1. The effects of shear rates on the viscosity of red blood cells diluted with autologous plasma at Hct 40, 30, 20, and 13% and with different volume expanders at Hct 30, 20, and 13% (n = 6 for each group)

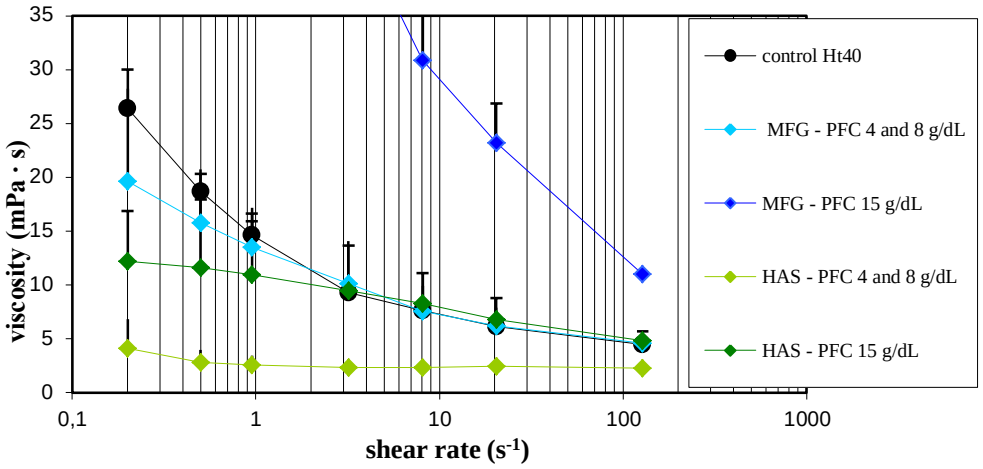

Fig. 2. The effects of shear rates on the viscosity of red blood cells mixed with volume expanders plus different PFC emulsion concentrations at Hct 13%

When hemodilution reached a final Hct 13%, and was made with HAS, a strong decrease of blood viscosity was observed. When 15 g/dL of PFC emulsion was added, this restored the physiological viscosity (NS vs control at Hct 40%) (fig. 2). A similar viscosity as control 40% Hct was observed in the presence of MFG and PFC 4 and 8 g/dL. In contrast to what was observed with HAS, when all the other volume expenders studied were mixed with 15 g/dL PFC to obtain identical hemodilution, the viscosity was always higher than the physiological value (Hct of 40%). However, at these same Hct values, HAS with lower PFC emulsion concentrations (4 and 8 g/dL) led always to viscosity values below those observed at Hct 40%.

When hemodilution reached a final Hct of 20% (fig. 3), blood viscosity was significantly higher than the physiological viscosity with MFG and PFC of 8 and 15 g/dL respectively. Viscosity values were similar to physiological values for MFG PFC 4 g/dL and HAS PFC 15 g/dL. All other combinations of volume expanders and PFC at different concentrations resulted in viscosity values below the physiological ones (fig. 3).

When hemodilution reached a final Hct of 30% (fig. 4), blood viscosity was significantly higher than the physiological viscosity with MFG and PFC of 4 and 8g/dL respectively. Viscosity values were similar to physiological values for HAS PFC 4 and 8g/dL. All other combinations of volume expanders and PFC at different concentrations resulted in viscosity values below the physiological ones (fig. 4).

DISCUSSION

The effects of PFC on blood rheology are more difficult to analyze because in clinical practice, the final results of resuscitation with volume expanders and oxygen carriers is a complex mixture of native red

blood cells, plasma, volume expanders and eventually PFC. These complex mixtures could have unpredictable effects on blood rheology.

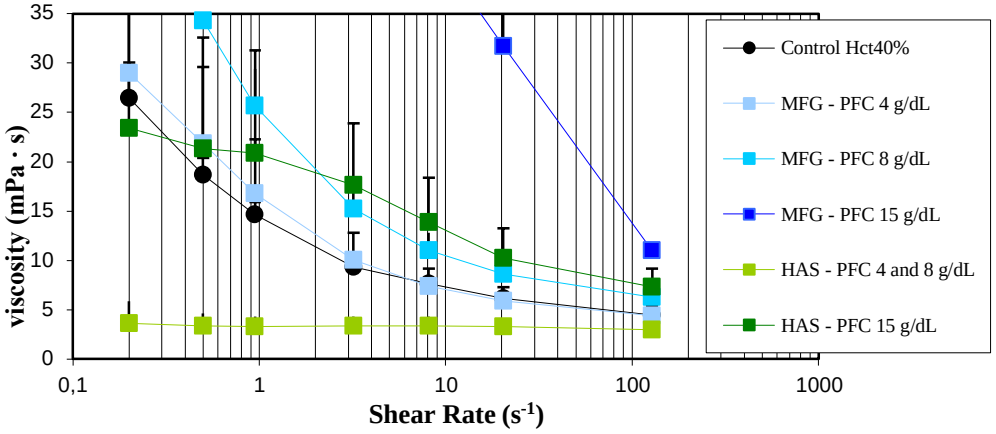

Fig. 3. The effects of shear rates on the viscosity of red blood cells mixed with volume expanders plus different PFC emulsion concentrations at Hct 20%

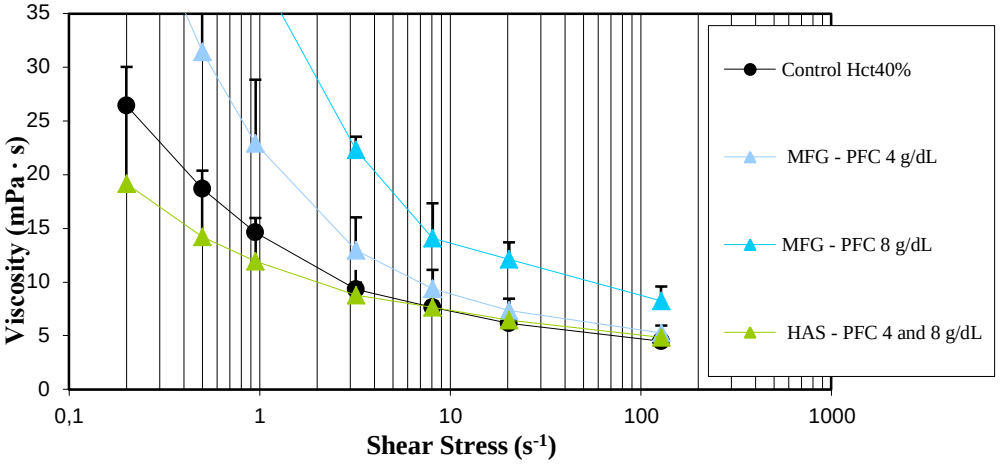

Fig. 4. The effects of shear rates on the viscosity of red blood cells mixed with volume expanders plus different PFC emulsion concentrations at Hct 30%

We measured *in vitro* the viscosity of human whole blood diluted with the PFC emulsion mixed with different volume expanders. Three PFC concentrations were tested: 4, 8 and 15 g/dL each combined with Hct of 13, 20 and 30%. Controls used were human whole blood at 40% Hct (physiological blood viscosity values) and

diluted with autologous plasma or the respective volume expanders at Hct 13, 20 and 30%.

For this study, we have chosen different PFC concentrations: 4 g/dL, 8 g/dL and 15 g/dL. The higher doses, although not used in clinical practice could allow to magnify potential effects and to better resolve trends in the rheological behavior of mixtures. Different shear rates (2.8 to 128 s^{-1}) which represent the different blood flow inside post capillary venules and large vessels (7). Different Hct values to explore the different cases susceptible to be meeting in acute clinical situation such as HS (Hct values of 10-15%) or cardiopulmonary bypass (Hct values of 20-30%).

Freyburger *et al* have shown significant alterations on the blood rheological properties *in vivo* hemodilution situation (8). MFG has been shown to facilitate red blood cell aggregation *in vitro* by reducing the electrostatic repulsive forces after adsorption on the cell membrane. MFG has been shown to interact specifically with plasma proteins such as fibronectin, and also may enhance the formation of bridges between red blood cells (9).

The effect of PFC on the rheological parameters of blood in a living organism at the Hct twice lower than the normal values was studied by Kuznetsova *et al*. (10). These authors showed that an increase in emulsion concentration leads to an increase in blood asymptotic viscosity and the aggregation of erythrocytes. It was concluded that only a small volume of PFC emulsion, as compared with the total amount of erythrocytes, can improve the blood fluidity upon disturbed circulation. The results suggest that PFC and MFG interact to increase viscosity and even at low doses of PFC and low Hct values, the presence of MFG results in viscosity values above those considered to be physiological.

CONCLUSIONS

The main findings of this study are that: addition of PFC, even at low clinically used concentrations, to different volume expanders, in the absence or presence of RBC, always resulted in increased viscosity values. At several concentrations, PFC increased viscosity values above the physiological values (that measured for 40% Hct in plasma). For instance, at an extreme Hct value of 13%, the addition of MFG, 4 g/dL of PFC restored the physiological viscosity values. For higher PFC concentrations, viscosity is dramatically higher than physiological values even at such low Hct values. These observed viscosities were more important when Hct was increased.

If the concentrations of PFC must be increased, the albumin solution has the smallest effect on blood rheology.

NEWS

NEW TARGET FOR THE OLD ASPIRIN

Non-steroidal anti-inflammatory drugs (NSAIDs), such as aspirin, a classical and authentic cyclooxygenase (COX) inhibitor, reduces the risk of developing several types of cancer. On site of inflammation, induction of COX-2 quickly results in the biosynthesis of prostaglandins leading to inflammatory response. Overexpression of inducible COX-2 and an increased prostaglandin biosynthesis play a significant role in carcinogenesis. Ogawa and coworkers investigated the effect of aspirin on regional lymph node metastasis during the development of lung cancer in mice. The carcinoma model was obtained by injecting a solution containing Lewis lung carcinoma (LLC) cells overexpressing green fluorescent protein (GFP) and BD Matrigel in the male mice lungs. Operative mortality was 10%. Single pulmonary nodules developed at the implanted site in 95% of animals, and regional mediastinal lymph node metastasis were observed 14 days after LLC-GFP cell injection in mice. Aspirin was orally administered (100 mg/kg, twice a day) after LLC-GFP cell injection. The reducing of percentage metastasis to regional lymph nodes was observed beginning with day 12 (63%), with no significant suppression of primary tumor growth in the lungs. Aspirin treatment led to a significant reduction in mortality (survival rate 70%; $P < 0.0001$). The authors suggested that COX inhibitors have potential to prevent lymph node metastasis (Ogawa F, Amano H, Ito Y, Matsui Y et al. Aspirin reduces lung cancer metastasis to regional lymph nodes. *Biomed Pharmacother* 2014; 68:79–86).

POLYPHENOLIC CONTENT AND ANTIOXIDANT ACTIVITY OF AN EXTRACTIVE FRACTION FROM *ABIES ALBA* BARK (Abstract): The wood of mature *Abiesalba*Mill. (silver fir) trees is used in construction and furniture industries, the bark being the main waste product. **Aim:** This study aimed to investigate possible therapeutic applications of *Abiesalba* bark waste. **Material and methods:** A raw extract and four extractive fractions were obtained from silver fir bark. They were also studied regarding their polyphenolic content (Folin-Ciocalteu assay). The ethyl acetate extractive fraction was further studied regarding its ability to scavenge free radicals (DPPH, superoxide anion and hydroxyl radicals) and to chelate ferrous ions. **Results and discussion:** The ethyl acetate fraction contained the highest amount of polyphenols (47.72 ± 0.38 g gallic acid equivalents/100 g). Its DPPH scavenging and ferrous ions chelating abilities (EC_{50} = 7.9± 0.1 and 1.56 ± 0.05μg/ml) were comparable to those of the positive controls, catechin (EC_{50} = 7.10± 0.05 μg/ml) and EDTA-Na_2 (EC_{50} = 1.27± 0.01μg/ml), respectively. It also scavenged superoxide anion and hydroxyl radicals with EC_{50} values of 53.30± 5.91 and 63.12 ± 1.78μg/ml, respectively. **Conclusions:** The ability of the ethyl acetate fraction to scavenge free radicals and chelate ferrous ions justifies further studies on the possible therapeutic applications of its antioxidant potential. **Keywords:***ABIES ALBA*MILL., POLYPHENOLS, DPPH RADICAL, SUPEROXIDE ANION RADICAL, HYDROXYL RADICAL, FERROUS IONS.

In the last years, there was a special interest for the study of polyphenols, especially proanthocyanidins – condensed flavan-3,4-diol structures (1, 2). One of the most studied extracts is Pycnogenol® (Horphag Research Ltd, Geneva, Switzerland). This is an extract isolated from the maritime pine (*Pinusmaritima* Mill.) bark containing proanthocyanidins, phenolic acids and flavonoids. Pycnogenol® acts as a scavenger for reactive oxygen species. Therefore, it reduces the incidence of mutagenic DNA damage and protects normal cells from the cytotoxic effects of oxidative stress. Pycnogenol® stimulates the activity of certain intracellular enzyme systems with antioxidant effects (superoxide-dismutase, catalase, glutathione-peroxi-

dase, glutathione-reductase) (3). The promising results of these investigations on Pycnogenol® justify the present study aiming to evaluate the antioxidant potential of polyphenols from another conifer bark.

Abiesalba Mill. (*Pinaceae*, silver fir) is naturally spread in the highlands of Romania. It is also planted as forest species, its wood being used as raw material in furniture industry or as building material. The aim of this research was to explore possible medicinal applications for the bark - the main waste from the industrial processing of the wood of mature silver fir trees. For this purpose, a raw extract and four fractions were isolated from silver fir bark using a fast and inexpensive method. The ethylacetate fraction, having the highest polyphenolic content, was subjected to several *in vitro* antioxidant assays.

MATERIAL AND METHODS

Plant material. *Abiesalba* Mill. bark was collected in February 2008 in Bicaz area, Neamț district. The bark samples were dried at room temperature in the dark for two weeks.

Extraction and fractionation.Silver fir bark (150 g), dried and powdered, was extracted with 1500 ml of 80% methanol for 1 h using a magnetic stirrer (FALC F-30ST magnetic stirrer). The extraction was repeated two times. The combined extracts were concentrated under reduced pressure (Büchi R-210 rotavapor, Büchi V-850 pressure controller, Büchi V-700 vacuum pump) and then lyophilized (Unicryo TFD 5505 freeze-dryer). 17.44 g of dry raw extract were obtained. 16 g of the raw extract were suspended in 160 ml of double distilled water and successively extracted with 5×160 ml of diethyl ether, 9×160 ml of ethyl acetate and 10×160 ml of n-butanol. The extractive fractions were concentrated under reduced pressure while the remaining aqueous phase was lyophilized.

Quantification of total phenolic content.Total phenolic content was determined by the Folin-Ciocalteu method (4). Extracts (1 mg/ml in DMSO; 40 μL) were mixed with water (3.16 ml) and Folin-Ciocalteu's phenol reagent (0.2 ml). After 5 min., 20% sodium carbonate solution (0.6 ml) was added. The solutions were mixed and left standing at room temperature. After 2 h the absorbance was measured at 765 nm. The results were expressed as g of gallic acid equivalents (GAE)/100 g extract.

DPPH radical scavenging assay.Free radical scavenging activity was evaluated by testing the ability to scavenge diphenylpicrylhydrazyl (DPPH) radical (5). Different concentrations of the sample to be tested (0.31-5 mg/ml in DMSO; 50 μL) were added to a solution of DPPH in methanol (A_{517nm}=1.00 ± 0.05; 2.95 ml). After 5 min., the absorbance was measured spectrophotometrically at 517 nm. (+) Catechin hydrate was used as positive control. Percent DPPH radical-scavenging activity was calculated using the formula: $100 \times (A_{start} - A_{end})/(A_{start})$ where A_{start} is the absorbance before adding the sample and A_{end} is the absorbance measured 5 min. after adding the sample.

Superoxide anion radical scavenging assay.Superoxide anion radical scavenging activity was evaluated according to a described procedure with minor changes (6, 7). All reagents were prepared in 100 mM phosphate buffer (pH 7.4). The reaction mixture contained different concentrations of sample (20.16-322.56 μg/ml), nitrobluetetrazolium (25 μM), beta-nicotinamide adenine dinucleotide reduced (NADH, 78 μM) and phenazine methosulphate (10

μM). After 2 min. the absorbance was read at 560 nm. (+) Catechin hydrate was used as positive control. Percent superoxide anion radical scavenging activity was calculated using the formula: $100 \times (A_{control} - A_{sample})/(A_{control})$.

Hydroxyl radical scavenging assay.Hydroxyl radical scavenging activity was assayed by the deoxyribose method (8, 9). Briefly, the sample (0.62-10 mg/ml in ethanol; 95 μL) was mixed with 5 mM 2-deoxy-D-ribose (0.4 ml) and phosphate-saline buffer (0.1 M; pH 7.4) up to a final volume of 1.6 ml. After addition of 2 mM $FeSO_4 \times 7H_2O$ (0.2 ml), the mixture was incubated at 37ºC for 1 h. Then 1% thiobarbituric acid (1 ml) and 2.8% trichloroacetic acid (1 ml) were added followed by heating for 15 min. at 100ºC. The mixture was cooled and the absorbance was measured at 532 nm. (+) Catechin hydrate was used as positive control. Percent hydroxyl radical scavenging activity was calculated using the formula: $100 \times (A_{control} - A_{sample})/(A_{control})$.

Ferrous ion chelating assay.Ferrous ion chelating activity was estimated according to a literature procedure (10, 11) with minor changes. The assay was carried out in 20 mM potassium phosphate buffer (pH 7.2). The sample was mixed with a solution of 2 mM $FeCl_2 \times 4H_2O$ (0.05 ml). After 1 min., 5 mMferrozine (0.2 ml) was added followed by vigorous shaking. The absorbance of the ferrozine-ferrous ions complex was measured at 562 nm. Ethylenediaminetetraacetic acid disodium salt (EDTA-Na_2) served as positive control. The percentage of ferrous ion chelating activity was calculated using the formula: $100\times (A_{control} - A_{sample})/(A_{control})$.

RESULTS AND DISCUSSION

*Extraction and fractionation.*In order to obtain a polyphenol-rich extract, *Abiesalba* Mill. bark was extracted with 80% methanol - a common solvent used for polyphenols extraction from vegetal sources. The hydromethanolic raw extract (AA) was fractioned with solvents of different polarities; four extractive fractions were obtained containing phytochemicals soluble in diethyl ether (AA-1), ethyl acetate (AA-2), n-butanol (AA-3) and water (AA-4). The three organic fractions were concentrated under reduced pressure leading to 1.30 g of AA-1, 2.04 g of AA-2 and 5.67 g of AA-3. The remaining aqueous phase was lyophilized and 6.84 g of AA-4 were obtained. Extracts were stored at -20°C until use.

*Quantification of total phenolic content.*Fraction AA-2 contained the largest amount of polyphenols (47.72 ± 0.38 g gallic acid equivalents/100 g). The lowest polyphenolic content was determined in fraction AA-1 (15.02 ± 0.31 g gallic acid equivalents/100 g) (tab. I).

TABLE I

Total phenolic content of raw extract and extractive fractions from*Abies alba* Mill. bark

Extract / Extractive fraction	Total phenolic content (g gallic acid equivalents/100 g extract or extractive fraction)
AA	29.86 ± 1.07
AA-1	15.02 ± 0.31
AA-2	47.72 ± 0.38
AA-3	26.92 ± 0.14
AA-4	27.20 ± 0.30

values are means of three replicates ± SD

Both normal-phase and reversed-phase HPLC-DAD analysis of silver fir bark extracts revealed the presence of low molecular phenolics in fractions AA-1 and AA-2 while fractions AA-3 and AA-4 contained proanthocyanidin-type polymers (data not shown). Highly polymerized proantho cyanidins are poorly absorbed in the gut and poorly metabolized by the intestinal microflora. In addition, polymeric proantho cyanidins bind to proteins, starch and enzymes forming complexes which cannot be absorbed. Low molecular polyphenols have a high bioavailability being absorbed in the gut (12). Fraction AA-2 contained the largest amount of polyphenols, mainly low molecular compounds and therefore it was chosen for further studies.

DPPH radical scavenging assay. Scavenging of free radicals is one of the main mechanisms by which polyphenols act as antioxidants. Polyphenols scavenge DPPH radical by donating hydrogen atoms of phenolic hydroxyls and transfering an electron from phenolic hydroxyls or phenoxide anions. Both the solvent and the redox potentials of polyphenols affect the mechanism of radical scavenging. Polar solvents (methanol, ethanol) form strong hydrogen bonds with phenolic hydroxyl groups and therefore, in polar solvents, electron transfer is the major mechanism by which polyphenols scavenge DPPH radical; in apolar solvents, hydrogen donation prevails (13). Fraction AA-2 and catechin scavenged DPPH radical in a concentration dependent manner. According to the EC_{50} values, the scavenging ability of fraction AA-2 (EC_{50} = 7.9 ± 0.1 μg/ml) was comparable to that of catechin (EC_{50} = 7.10 ± 0.05 μg/ml) (tab. II).

Superoxide anion radical scavenging assay.Despite a low reactivity and a low capacity of crossing cell membranes, superoxide anion radical is toxic due to its capacity to promote DNA damage. Superoxide anion radical does not react with DNA directly. Its DNA damaging potential is due to the conversion into highly reactive hydroxyl radical through iron-induced redox reactions (14). The effect of fraction AA-2 on superoxide anion radical was evaluated by measuring the inhibition of NADH-dependent nitrobluetetrazolium reduction. In this assay, superoxide anion radical is generated in a NADH-phenazinemethosulphate system. Once generated, superoxide radical reduces nitro bluetetrazolium to blue formazan which is measured spectrophotometrically at 560 nm. In the presence of antioxidants, the formazan production is diminished; the decrease in absorbance at 560 nm is proportional with the superoxide scavenging activity (6, 7). Both fraction AA-2 and catechin scavenging effects were concentration dependent. Fraction AA-2 scavenging activity increased from 24.13±0.69% at 20.16 μg/ml to 82.81± 0.79% at 322.56 μg/ml. At the same concentrations, catechin scavenged superoxide radical by 32.57±0.06% and 92.53±0.12%, respectively. According to the EC_{50} values, fraction AA-2 (53.30 ± 5.91 μg/ml) had a lower scavenging activity in comparison to catechin (39.53 ± 0.95 μg/ml) (tab. II).

Hydroxyl radical scavenging assay.Hydroxyl radical is considered to be the most deleterious reactive oxygen species. As it has an extremely short half-life and a low diffusion capacity, hydroxyl radical will damage the closest biomole-

cules immediately after its generation. In case hydroxyl radical is produced in immediate vicinity of nucleic acids, it may oxidize DNA directly. The effect of fraction AA-2 on hydroxyl radical was estimated using 2-deoxy-D-ribose degradation assay (8, 9). Hydroxyl radicals generated by iron (II) sulfate heptahydrate in phosphate buffer damage 2-deoxy-D-ribose with the release of thiobarbituric-acid reactive material which is spectrophotometrically quantified at 532 nm. The decrease of absorbance at 532 nm indicates hydroxyl radical scavenging activity. Hydroxyl radical scavenging activity of fraction AA-2 increased from 17.06±0.18% at 15.62 μg/ml to 70.41±0.76% at 250 μg/ml. The scavenging effects of the positive control, catechin, were 27.14±0.97% at 15.62 μg/ml and 76.36±0.34% at 250 μg/ml. As compared by the EC_{50} values, fraction AA-2 (63.12 ± 1.78 μg/ml) showed less hydroxyl radical scavenging activity than the positive control, catechin (46.16 ± 0.72 μg/ml) (tab. II).

Ferrous ion chelating assay.Ferrous ions are involved in the generation of reactive oxygen species, mainly hydroxyl radical *via* autoxidation and Fenton/Haber-Weiss reactions. Iron-induced reactive oxygen species inhibit tumor suppressor genes increasing the risk of cancer development (14). Ferrous ions chelation is another mechanism by which polyphenols act as antioxidants. The ferrous ions chelating activity was evaluated by the ferrozine assay. Ferrozine binds ferrous ions forming red coloured complexes with a strong absorbance at 562 nm. Chelating agents reduce ferrozine-ferrous ions complex formation with a decrease in absorbance at 562 nm (10, 11). Fraction AA-2 and EDTA-Na_2 chelated ferrous ions in a concentration-dependent manner. The positive control, EDTA-Na_2 and fraction AA-2 showed comparable chelating effects (EC_{50} = 1.27 ± 0.01 μg/ml and 1.56 ± 0.05 μg/ml, respectively) (tab. II).

TABLE II

EC_{50} values (μg/ml) of fraction AA-2 in different antioxidant assays

Sample	DPPH radical scavenging activity	Superoxide anion scavenging activity	Hydroxyl radical scavenging activity	Ferrous ion chelating activity
AA-2	7.9 ± 0.1	53.30 ± 5.91	63.12 ± 1.78	1.56 ± 0.05
catechin	7.10 ± 0.05	39.53 ± 0.95	46.16 ± 0.72	n.d.
EDTA-Na_2	n.d.	n.d.	n.d.	1.27 ± 0.01

values are means of three replicates ± SD; n.d. – not determined

CONCLUSIONS

This study demonstrated that an ethyl acetate extractive fraction (AA-2) isolated from the bark of mature *Abies alba* Mill. trees effectively scavenged free radicals (DPPH, superoxide anion and hydroxyl radicals) and chelated ferrous ions. Our findings justify further studies on the identification of the active constituents and *in vivo* antioxidant activity of fraction AA-2.

SYNTHESIS AND EVALUATION OF ANTIOXIDANT ACTIVITY OF SOME NEW BENZYLIDENE-THIAZOLIDINE-XANTHINE DERIVATIVES (Abstract): The International Diabetes Federation reported that 246 million adults worldwide had diabetes mellitus and the prevalence of this syndrome was expected to increase continuously. **Aim:** To design new compound with potential antidiabetic and antioxidant activity. **Material and methods:** New benzylidene-thiazolidine derivatives (BT2a-2e) were obtained by condensation of xanthine-thiazolidine-4-one (TZ-4-one) with aromatic aldehydes. The synthesized compounds were characterized by spectral method (IR, ^{1}H-NMR, ^{13}C-NMR) and their antioxidant potential has been also evaluated. **Results:** The synthesized compounds have important antioxidant effects as compared to xanthine-thiazolidine derivatives. The most active compounds were those obtained by condensation with 4-dimethylaminobenzaldehyde (BT2c) and 4-nitro-benzaldehyde (BT2e). **Conclusions:** The chemical modulations performed on the structure of TZD-4-one have a good influence on their antioxidant potential. **Keywords**: XANTHINE, THIAZOLIDINE, SPECTRAL METHODS, ANTIOXIDANT

Type 2 diabetes mellitus (T2DM) is considered to be the „epidemic of the 21st century" and the discovery of new therapies is a challanges for researchers. An inadequate glycemic control can be the leading cause of cardiovascular disorders, blindness, renal failure and amputations (1).

Due to the complex nature of this disease and decreased beta cell function, the management of glycemic control is difficult. There are currently used distinct classes of hypoglycemic agents: biguanides, sulfonylureas, meglitinides, thiazolidinediones, α-glucosidase inhibitors. The disadvantages of this therapy are the multiples side effects (weight gain, lactic acidosis, flatulence, oedema, fracture, liver and renal failure, pancreatitis) and more importantly the difficulty to obtain a good glycemic control. The new goal in T2DM management is the development of incretin modulators and dipeptidyl peptidase IV inhibitors (DPP IV).

DPP IV inhibitors are of considerable

interest to the pharmaceutical industry and intense researches in this area have resulted in the release to the market of such drugs as: sitagliptin, saxagliptin, linagliptin, alogliptin, vildagliptin (2). Linagliptin is a xanthine-based orally administered long acting drug, which at a 5 mg dose inhibits DPP IV activity more than 80% (3).

Hyperlipidemia and free radicals are among the most important factors involved in the pathogenesis of diabetes. Persistent hyperglycemia causes increased production of free radicals, especially reactive oxygen species resulting from glucose auto-oxidation and protein glycosylation (4).

This study presents the synthesis, physico-chemical and spectral characterization, and evaluation of the antioxidant activity of new xanthine scaffold benzylidene-thiazolidine-4-ones, in order to obtain new compounds with potential antidiabetic and antioxidant action.

MATERIAL AND METHODS

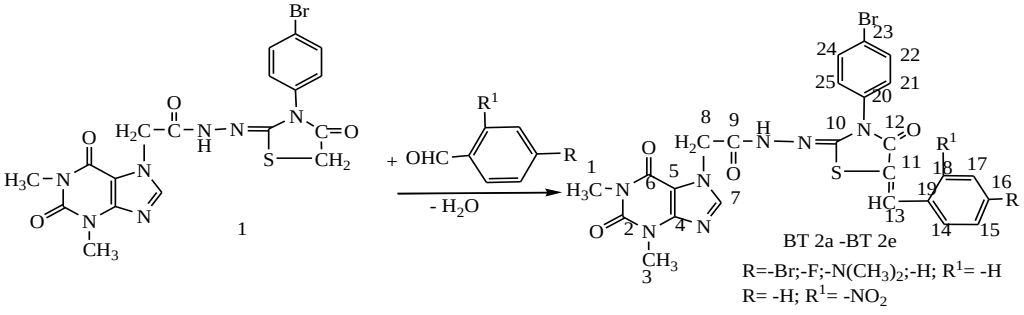
4-brom/4-fluor/4-N-dimethylamino/2-nitro-benzaldehyde; vitamin C; vitamin E; DPPH; ABTS, potassium persulfate; monosodium and disodium phosphate; ammonium molybdate; potassium ferricyanide; trichloracetic acid; iron chloride. ^{1}H-NMR and ^{13}C-NMR were recorded in DMSO-d_6 with a BrukerAvance 300 MHz instrument. The chemical shift was expressed in ppm as a function of tetramethylsilane (TMS) as internal standard. FTIR spectra were recorded on a Biorad FT-IR- FTS 575C spectrophotometer. All melting points were determined on Buchi B-540 Melting Point apparatus.

Chemistry

The compounds were obtained through condensation of 2-{2-[2-(1,3-dimethylxanthin-7-yl)acetyl]hydrazono}-3-(4-brom) phenylthiazolidin-4-one (TZ-4-one, 1) with different substituted aromatic aldehydes, by adapting similar methods described in the literature (5) (Scheme 1).

General procedure for BT 2a-2e synthesis

2-{2-[2-(1,3-dimethylxantin-7-il)acetyl]-hydrazono}-3-(4-brom)phenylthiazolidin-4-one (4g, 0.0079 mol) was dissolved in 100 ml dioxane. To this solution aromatic aldehyde (0.0079mol) and piperidine (0.00395) were added as catalyst and maintained under reflux for 6 h. The solvent was removed under reduced pressure and the final compound was precipitated in cold water. The solid product separated was filtered, washed with excess of cold water, dried and recrystallized from dioxane.



Scheme 1. Synthesis ofxanthine scaffold benzylidene-thiazolidine-4-one derivatives

2-{2-[2-(1,3-dimethy-xanthine-7-yl)acethyl]hydrazono}-5-(4-florbenzylidene)-3-(4-brom-phenyl)-thiazolidine-4-one (**BT2a**). EVALUATION OF ANTIOXIDANT ACTIVITY

Evaluation of antioxidant activity through phosphomolybdenic method. Different sample concentrations were obtained by dilution of stock solutions (5 mg/ml). An aliquot of sample solution (0.2 ml) was mixed with the reagent solution (2ml, 28 mM sodium phosphate; 4 mM ammonium molybdate; 0.6 M sulphuric acid). The samples were incubated at 95^0C for 90 min and then centrifuged; absorbance was measured at 695 nm. The antioxidant activity of the samples was compared with that of vitamin C (2mM) (6).

Reducing power assay. The compounds possessing electron donating groups reduce Fe^{3+} to Fe^{2+} and with iron chloride form Berlin blue with a maximum absorbance at 700 nm. To 1 ml of sample solutions obtained from stock solution (5 mg/ml), 1 ml buffer phosphate (pH 6.6) was added. The mixture was shaken vigorously and 1 ml potassium ferricyanide 1% was added. After incubation 20 min at 50^0C 1 ml trichloracetic acid 10% was added and then centrifuged at 4500 rpm for 15 minutes. To 1 ml of supernatant, 1 ml distilled water and 0.2 ml ferric chloride 0.1% were added. After 5 min the absorbance was measured at 700 nm. Vitamin C was used as reference (7).

*Scavenging effect of antioxidant activity on DPPH radical.*DPPH is a stable free radical that can accept hydrogen atoms. The reduced form of DPPH is 2,2-diphenyl-1-picrylhydrazyne of yellow color. Various concentrations of the test compounds in 200 µl DMSO were added over 2500 µl solution of DPPH radical in methanol (0.1 mM). The mixture was allowed to stand for 1 hour in the dark and then absorbance was measured at 517 nm against a blank using the UV-VIS spectrophotometer. The radical scavenging capacity was calculated according to the following equation: $I\% = (Abs_{t=o} - Abs_{t=60\ min} / Abs_{t=0})x\ 100$. $Abs_{t=60min}$ is the test compound absorbance after 1 hour. $Abs_{t=0}$ is absorbance of 0.1 mM DPPH methanol solution at 517 nm. Vitamin E was used as reference (8).

*Scavenging effect of antioxidant activity on ABTS radical.*The$ABTS^+$ radicals were produced by reacting ABTS (7mM) (2,2`-azino-bis (3-etylbenzothiazoline-6-sulphonic acid) with ammonium persulphate (2.45 mM) for 16 hours in the dark as described in literature (9). This stock solution was diluted with ethanol to obtain a solution with absorbance of 0.7 ± 0.02 at 734 nm. The tests compounds were dissolved in DMSO-ethanol (5 mg/ml) and 0.02 ml of different concentrations was added to 1.980 ml ABTS solution. After 6 min the absorbance was measured and the radical scavenging capacity was calculated according to the following equation: $I\% = 100 \times (A_{inițial}-A_{final}) / A_{inițial}$, where the $A_{inițial}$= absorbance before adding the sample, $A_{fina\ l}$= absorbance after 6 min of reaction. Vitamin E was used as referee.

RESULTS AND DISCUSSION

The conclusions referring to antioxidant activity pointed out that the chemical modulations on the structure of 2-{2-[2-(1,3-dimethylxanthine-7-yl)acethyl] hydrazono}-3-(4-brom)phenylthiazolidine-4-one (TZD-4-one) through their condensation with different aromatic aldehydes (benzaldehyde, 4-brom/4-fluor/4-dimethylamino/ 2-nitrobenzaldehyde) have a good influence on the antioxidant potential, all tested compound being more active than TZD-4-one. As to the antioxidant activity determined by phosphomolybdic reagent reduction method, it has been noticed that the

most active compounds are BT2c (EC50=29.37) and BT2e (EC50=33.13), obtained through condensation with 4-dimethylaminobenzaldehyde and 2-nitrobenzaldehyde, being more active than TZD-4-one (EC50=136.9) by up to 4.7 and 4.2 times, respectively (fig. 1). These compounds were proved to be the most active of all, reducing power included; BT2c (EC50=23.13) was 6 times and BT2e (EC50=41.6) 3.3 times more active than TZD-4-one (EC50=137.857) (fig. 2).

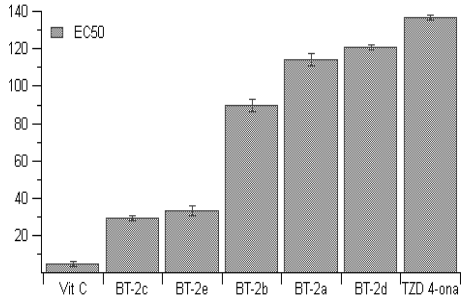

Fig. 1. Antioxidant activity

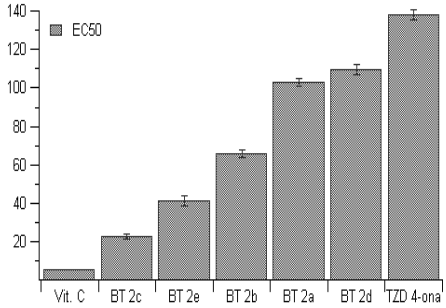

Fig. 2. Reducing power assay

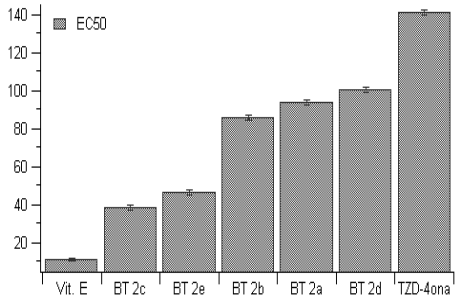

Fig. 3. Radical scavenging activity (DPPH)

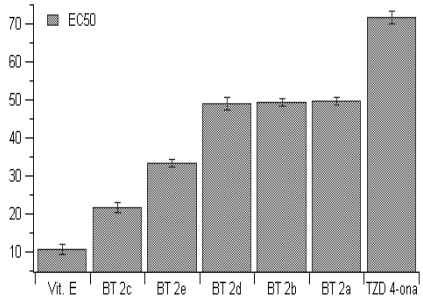

Fig. 4. Radical scavenging activity (ABTS)

The study of radical scavenging action determined by the reduction of DPPH (fig. 3) and ABTS radicals (fig. 4) showed that compound BT2c was the most active of them. Its scavenging activity was 3.7 times (EC50=38.13, DPPH method), and 3.3 times (EC50=21.17, ABTS method), respectively more intense than that of TZD-4-one. An appreciable antioxidant activity compared with TZD-4-one was also found for BT2e (EC50=46.53 and 33.2, respectively).

CONCLUSIONS

New benzylidene-thiazolidine derivatives with xanthine moiety have been synthesized, and physico-chemically characterized (melting point, yield, solubility in different organic solvents). Chemical structure was confirmed by spectral methods

(IR, ^{1}H-NMR, ^{13}C-NMR). The antioxidant potential of the synthesized compounds was evaluated, their antioxidant activity, reducing capacity and scavenging activity (by DPPH and ABTS methods) being determined. The most active proved to be the compounds resulted from condensation with 4-N-dimethylaminobenzaldehyde (BT2c) and 2-nitrobenzaldehyde (BT2e).

DEFINING FAMILY ELEMENTS IN ADOLESCENCE (Abstract): The family has a permanent partner role on adolescents till adult stage. The adolescent builds up his own identity based on the affiliation to his family, but he gets away from his family for the need of leading his own life and finding his place in society. The adolescent sample was made up of 2908 college students from Timis County, aged between 15-19 years, 51.5% girls and 48.5% boys. The working **method** was the populational transversal study based on anonymous self-administration of the investigation questionnaire CORT 2004 about the risky comportment in teenagers, in a CNCSIS research project. **Results**: The study results high lighten the predominance of family organized affiliation, 78.9% living with family, 88.6%; the medium study level of 63.7% of mothers and 59.1% of fathers; the satisfaction towards family members, 71.7%; satisfaction towards family's financial level, 61.2%. In this way is underlined the role of identity development in adolescents. **Keywords:** ADOLESCENT, FAMILY, POPULATIONAL STUDY.

The adolescence is linked to professional changes that are linked to family as a hole, but also the little groups that form the family. The adolescent develop from a necessary dependent relationship to a family independence relationship. He builds up his own identity based on the family affiliation. Meanwhile he gets away from family in the need of driving his own personal life and also finding a place in society. The adolescent`s world extends out of family, and the family influence is modified (1, 2, 3).

His parents' values can be questioned and the parents became people who can make mistakes. The adolescent behavioral changes to parents start with little autonomy, setting a distance towards family, and the smallest complicity towards parents. The adolescent starts to fell the taste of independence, he wants to decide by himself, he does not like his parent`s control, he also tries to show that he is not a kid anymore, he wants immediate freedom. There also can show conflicts coming from the protection and limits imposed by the family rules, but also from the adolescent`s wish for liberty, but without responsibility.

The parental perception on physical development, emotional and sexual maturity, is that of an adult that gets control of his life. Parents` functions, future aspirations projected on the kid can become without object and can create downs towards the relation with their own kid: refuses the change, constriction, depression, and the tendency of rejection his own kid seen as a

stranger.

A permanent role of family to be the partner of their young members grow-up. The values that family transmitted to children vary from respect towards age, intern and extern roles, capacity of facing the problems, the refinement of autonomy, self-esteem, creativity and imagination, and the real development of values in perfect harmony to society.

Nowadays, the time for children education decreases in traditional family because of social responsibilities and divorces or brake-ups crash the family. It is well-known the importance of family example towards the adolescent` behavior, the presence of risky behaviors in family members with bad impact (5, 6, 7).

MATERIAL AND METHODS

The study carried out on a representative sample of 2908 high school students from Timis County, aged between 15-19 years, girls – 51.5% and boys - 48.5%. The working method was the transversal population study based on anonymous self-administration of CORT 2004 questionnaire about the investigation of risky behavior in teenagers included a research project CNCSIS (8, 9, 10, 11, 12). The answering rate was: from classes - 97.9%; from high school pupils - 76.2%; the average rate – 74.6%. The data were processed using *EpiInfo*, version 6.04, 2001.

RESULTS AND DISCUSSION

How adolescents define their family. The majority of adolescents - 78.9% (2279), indicate the membership to an organized family, with mother and father. The frequency of the unorganized (one parent, divorce, death) family is on the second place with 13.5% (381), followed by reorganized families 7.6% (220) (tab. I).

TABLE I

How adolescents define their family

Where and with whom the adolescents live. The adolescents from the study live with families in 2565 cases (88. 6%), at the school nursery - 177 (6.0%), most boys than girls, and 3.8% (109) of those who were asked are hosted, frequently girls. A lot of 36 (1.2%) are students who live alone (tab. II).

The instruction level of parents. The frequent school graduated by parents is high school, especially by the mother. The percentage of the fathers who graduated is 34% (964), mothers 48.6% (1382). On the second place are parents who graduated professional schools, frequently fathers: 680 (25.1%) and 420 (15.1%) mothers. Those parents who graduated university are on the third place, frequently fathers: 615 (21.6%) and 505 (17.2%) mothers, followed by professional schools graduates, 344 (12.6%) fathers and 277 (9.9%) moth-

ers. The lowest frequency is of the parents who graduated general school or less, frequently mothers: 187 (6.7%) fathers and 253 (9.0%) mothers (tab. III, IV).

The satisfaction rate of adolescents towards their relation to family members. Towards parents: 2050 (71.7%) of the adolescents are satisfied with this relation, frequent boys. The young follow, they declare that are neither satisfied nor unsatisfied, with 669 (23.4%), more frequently girls than boys. Those that are not satisfied are 141 (4.9%), more frequently girls and 25 (0.9%) of the teenagers, boys and girls, answered

that they do not have parents (tab. V).

Towards brother or sisters, the same hierarchy of the satisfaction grades: satisfied - 1749 (77.2%), more frequently, boys; not satisfied, neither satisfied - 412 (18.1%), more frequently girls; unsatisfied - 106 (4.7%), more frequently girls (tab. VI) and 590 (20.3%) of adolescents do not have brothers - 301 (21.0%) of the girls and 280 (19.7%) of the boys.

If we compare the satisfaction rate towards the relationship with parents with that towards brothers and sisters, it is shown a higher satisfaction rate towards brothers, at the whole lot and both sexes. Boys are frequent satisfied with their relation towards family members, in comparison to girls (fig. 1).

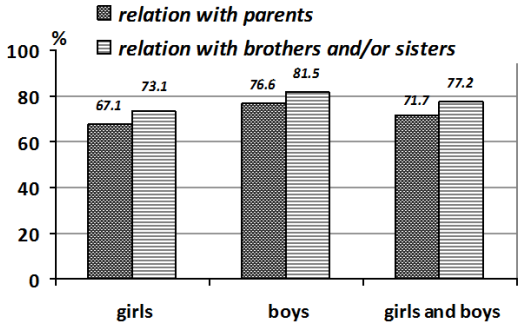

Fig. 1. Percentage distribution of satisfied adolescents towards their relationship with family members

Satisfaction rate of adolescents towards financial level of their family. Satisfaction towards the financial level of the family is predominant 1776 (61.2%), more frequently boys; 626 (21.6%) are not satisfied neither satisfied towards the financial level of their family, more frequently girls, and 471 (17.2%) are not satisfied, especially girls (tab. VII).

TABLE VII
Satisfaction rate of adolescents towards financial level of their family

Answers	Sex				Total	
	F		M			
	No.	Weighted percentage	No.	Weighted percentage	No.	Weighted percentage
Satisfied	843	56.5	933	66.2	1776	61.2
Not satisfied, neither satisfied	343	22.3	283	20.9	626	21.6
Unsatisfied	301	24.2	170	12.9	471	17.2

Non answers: 35

CONCLUSIONS

The result of the study underlines the predominance of family organized appurtenance, 78.9%; living with family, 88.6%; the medium instruction rate 63.7% of mothers and 59.1% of fathers; the satisfaction towards family members, 71.7%; the satisfaction towards the families' financial level, 61.2%. The role of family in adolescent`s life is certified through these examples.

IMMUNOHISTOCHEMICAL PROFILE OF THE ESTROGEN AND PROGESTERONE RECEPTORS IN MAMMARY BENIGN LESIONS (Abstract): The immunohistochemical diagnosis for estrogen and progesterone receptors must be carried out in the tracking of every primary tumor, benign or malign, especially in the case of in situ carcinoma. **Material and method**: We have studied the expression of estrogen and progesterone receptors in benign lesions, identifying phenotypes depending on the presence of estrogen and progesterone receptors. **Results**: The result "positive" or "negative" in the report sent to the doctor is not sufficient, the inclusion of the total score in the case of a positive result, the clone used, the usage / non-usage of antigenic exposure and also the quality control being necessary. The benign mammary lesions occur in the context of a hormonal imbalance, which, in the long run runs the risk of developing a mammary carcinoma. **Conclusion**: The further study of the hormonal spectrum of those lesions, considered as pre-malignant, may lead to the identification of some groups of hyperplastic lesions, presenting a high risk for developing a mammary cancer. **Key words**: MAMMARY TUMORS, IMMUNOHISTOCHEMICAL DIAGNOSIS, HORMONAL PROFILE

The hormones control the development of the mammary carcinomas and thus the hormonal treatment is the preferred treatment for the vast majority of the ER positive metastatic breast cancers. At present, the evaluation of estrogen and progesterone expression in mammary carcinomas and their interpretation as prognostic and predictive factors, in the antiestrogenic endocrine therapy are elements of the traceability in female patients with mammary tumors (1). The immunohistochemical diagnosis for the estrogen and progesterone receptors must be carried out in the tracking of every primary benign and malignant tumor, especially in the case of in situ carcinoma. The immunohistochemical testing for the estrogen and progesterone receptors is highly indicated in the mammary tumors recurrence and metastases, due to the well known capacity of the mammary carcinomas of changing their hormonal status during their evolution. The conversion from a negative ER status to a positive ER status is beneficiary for the patients, benefiting of endocrine therapy. Conversely, the disappearance of the positive ER status is associated with a marked tumoral aggressiveness and therapy resistance. The expression of the progesterone receptor is induced by estrogen and consequently is a functional marker for ER. The normal mammary tissue presents receptors for progesterone. In mammary tumors the PR

expression is similar or slightly inferior in density, in comparison with ER, but the staining intensity is higher. PR is a weaker predictor for the endocrine therapy response and it offers instead important information regarding the clinical evolution of the disease (2). The positive mammary tumors for ER and PR present a high degree of histopathological heterogenity, do not associate ganglionic metastases, present a reduced proliferation rate and have a better prognosis (3). The ER / PR mammary tumors are associated with a favorable response to endocrine therapy and only a reduced number of cases do not respond to this therapy, due to the expression of an altered form of receptors.

OBJECTIVES

We have studied the expression of the estrogen and progesterone receptors in the benign lesions identifying phenotypes depending on the presence of estrogen and progesterone receptors.

MATERIAL AND METHODS

Out of 91 cases of benign lesion evaluated (main and adjacent ones), 16 were fibroadenomas, 23 typical moderated and fluoride ductal hyperplasia, 6 atypical ductal hyperplasia, 11 adenosis and sclerosing adenosis , 17 cystic dilatations, 15 apocrine metaplasia , 1 Phyllodes tumor and 2 cases of intraductal papilloma. The immunehistochemical protocol in the case of ER and PR receptor was similar and has been applied on twin blade slides. In order to interpret the results for ER/PR using optical microscopy we have taken into account only the nuclear coloration pattern, using Allred or Quick score, which are a semiquantitative evaluations that includes density data, the intensity of the positive reaction and also grades the positive nuclei cell percentage (percentage score), using an intensity score (tab. I).

TABLE I

Allred quantification score for estrogen and progesterone receptors

Percentage score (PS)	**Intensity score (IS)**
0 = negative	0 = negative
1 = < 1% coloured nuclei	1 = weak positive
2 = 1-10% coloured nuclei	2 = moderate positive
3 = 11-33% coloured nuclei	3 = intensely positive
4 = 34-66% coloured nuclei	
5 = 67-100% coloured nuclei	
Total score (TS) = PS + IS TS = 2 – 8	

A score of 0, 1 or 2 (less than 10% weak colored positive nuclei) has been considered negative (0), a score of 3 and 4 was considered "1+", a score of 5 and 6 was considered "2+", and a score of 7 and 8 was considered"3+".

The result "positive" or "negative" in the report sent to the doctor is not sufficient, the inclusion of the total score in the case of a positive result, the clone used, the usage / non-usage of antigenic exposure and also the quality control being necessary. The correlation between the immunehistochemical score and the response rate to hormonal therapy will be attached:

Score 0 hormonal therapy is inefficient.

Score 2-3 – 20% chance of therapy response to anti-estrogen medication.

Score 4-6 – 50% response rate.

Score 7-8 – 75% positive response to therapy.

RESULTS

In the case of negative controlled sections, where the incubation phase with the primary antibody was omitted, no coloration has been noticed. The normal adjacent mammary tissue, used as internal positive control presented a positive reaction for estrogen and progesterone receptors. The positive cellular immunoreaction has been noticed only at nuclear level. The myoepithelial, myofibroblasts and fibroblasts from the stroma of each case did not present any positive reaction. The staining for progesterone receptors has been more intense than in the case of the estrogenic receptors, but the percentage of positive nuclei was higher than in the case of the estrogen receptors.

The unmodified mammary epithelium presented a non-uniform, diffuse expression of the estrogen and progesterone receptors, with a more obvious expression at the level of ductal epithelium, compared with the lobular epithelium. The estrogen receptors have been stated in 25.3% of the benign lesion cases, and the progesterone receptors have been stated in 33% of the main benign lesions and associated lesions. The distribution according to benign lesion type of the estrogen and progesterone receptors can be seen in table 2. We have encountered 13 cases of intra and pericanalicular fibroadenomas and also 2 cases in which the fibroadenoma has been associated with the phyllodes tumor. Out of the cases of fibroadenomas studied, we have encountered a number of 5/16 (31.25%) positive cases for ER and 9/16 (56.25%) positive cases for PR. The immunoreaction of hormonal receptors was present at the level of epithelial cells nuclei. The fusiforme proliferated stromal cells (fibrocite / fibroblasts) present as “spindle cells” were negative for hormonal receptors. From table II we can note the fact that most fibroadenomas were positive for progesterone receptors.

TABLE II

Estrogen and progesterone receptor distribution in the case of benign tumors encountered (including the associated lesions)

Histological type	Total number of lesions (n=91)	ER		PR	
		+ (n=23)	- (n=68)	+ (n=30)	- (n=61)
Fibroadenomas (FA)	16	5	11	9	7
Typical ductal hyperplasia (HDT)	23	6	17	8	15
Atypical ductal hyperplasia (HDA)	6	2	4	3	3
Adenosis and typical sclerosing adenosis (Ad)	11	8	3	7	4
Intraductal florid papiloma (Pp)	2	2	0	2	0
Apocrine metaplasia (MA)	15	0	15	0	15
Cystic dilatation (DC)	17	0	17	0	17
Phyllodes Tumor (TP)	1	-	1	1	-

Regarding the quantification of estrogen and progesterone receptor expression, the vast majority of the cases we have evaluated were slightly positive (1+) and only a small amount of cases were moderately positive (2+). Out of the two fibroadenomas cases associated with the invasive ductal carcinoma, one was positive both for ER and PR, and the carcinoma was well differentiated (G1); the case associated with weak differentiated carcinoma (G3) was negative for estrogen and progesterone receptors. The fibroadenomas associated with the phyllodes tumor was positive only for the progesterone receptors.

The typical ductal hyperplasia (fig. 1) was encountered in 23 cases, out of which 6 cases (26,08%) were ER positive and 8 cases (37,7%) were PR positive. The great majority of the cases were slightly positive for ER and PR (+1). The moderate or florid ductal hyperplasia is associated with a 1.5-2 times higher risk of developing a carcinoma.

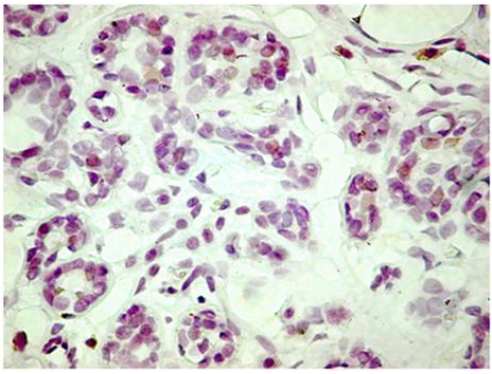

Fig. 1. The progesterone receptors expression in a typical ductal hyperplasia. One can notice heterogeneous distributed, positive nuclei, with an intensity score of 1+ and rare 2+ nuclei , with a percentage score of 3+ (around 30% positive nuclei)

Atypical ductal hyperplasia is associated with a 5 times higher risk of developing a carcinoma. We have encountered this type of lesion in 6 cases, which also presented malign lesions and DCIS (ductal carcinoma in situ), out of which 2 were ER positive (33.33%) and 3 cases were PR positive (50%).

We have encountered 12 cases of adenosis, as well as cases of sclerosing adenosis, out of which 8 cases were ER positive (72.7%) and 7 cases were PR positive (63.6%).

Intraductal florid papiloma was identified in 2 cases, positive for both ER and for PR.

In the case of apocrine metaplasia we have not noticed a positive reaction for estrogen or progesterone receptors. The ductal dilatation was negative for estrogen and progesterone receptors.

From table I one can notice that the majority of lesions (17) were quantified as being slightly positive (1+), regarding ER expression, 6 cases were moderate positive, most of them in the case of adenosis. As for the progesterone receptors expression, 22 cases were slightly positive, 7 were moderate positive and one case (adenosis) was intensely positive (fig. 2).

Depending on the estrogen and progesterone receptors, we have established the prevalence of four phenotypes ER/ PR in the case of the benign tumors (fig. 3).

Consequently, in case of fibroadenomas, we have encountered 4 cases (25%) for both estrogen and progesterone receptors (ER+/PR+), 1 case (6.25%) ER+/PR-, 5 cases (31.25%) ER-/PR+ and 6 cases (37.5%) ER-/PR-.

In the case of typical hyperplasia, 1 case (4,4%) was ER+/PR+, 5 cases (21.8%) were positive only for ER (ER+/PR-) , 7

(30,4%) were ER-/P+- and 10(43,47%) cases were negative (ER-/ PR-). Atypical hyperplasia presented the following phenotypes: 1 case (16.6%) ER+/PR+, 1 case (16.6%) ER+/PR- and 2 cases (33.3%) ER-/PR+ and ER-/PR-.

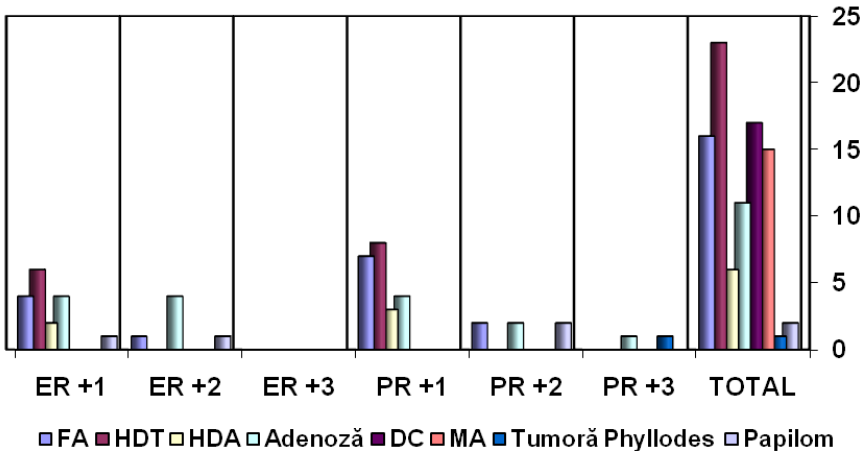

Fig. 2. ER and PR quantification of benign lesions.

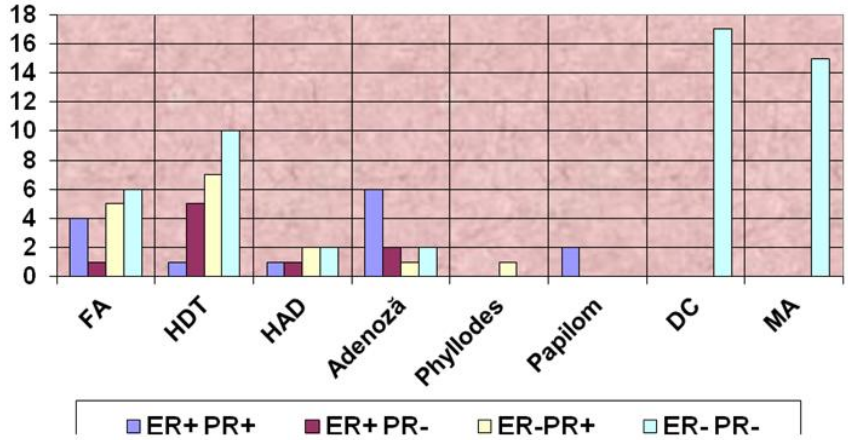

Fig. 3. ER / PR phenotype prevalence in the case of benign tumors

In the case of adenosis, 6 (54.54%) cases were ER+/PR+, 2 cases (18.18%) were ER+/PR-, 1 case (9%) was ER-/PR+ and 2 cases (18.18%) were ER-/PR-. The Phyllodes tumor encountered presented an ER-/PR+ phenotype. The florid intraductal papilomas were positive both for estrogen and progesterone receptors (ER+/PR+). The non-proliferative lesions, represented by cystic dilatations and apocrine metaplasia were not positive for ER/PR. Out of the positive cases, the most frequently encountered phenotype was ER-/PR+, followed by ER+/PR+.

DISCUSSION

The benign mammary lesions occur in the context of a hormonal imbalance, which, in the long run runs the risk of developing a mammary carcinoma. The activation of α estrogen receptor (ER-α) raises the sensitiveness of the target tissue for the action of circulatory estrogens, stimulating the DNA synthesis, cell division, active biological protein production, including pS2, TGF-α (transforming growth factor), EGF (epidermal growth factor), which influences the cellular growth and differentiation (4). The cumulative exposure to estrogens contributes to the mammary carcinogenesis by means of stimulating a premalignant cells clone or the augmentation of spontaneous mutation percentage. The estrogens may also decrease the transition time in the cellular cycle, so that the spontaneous mutations become defined before the reparatory mechanism intervention. Another mechanism could be the toxic genetic effect of estrogens. It can be explained by the loss of the suppressing gene effect, whose function is to prevent the excessive proliferation of ER positive cells in the rich estrogens environment, especially in premenopausal women (5). The allelic disequilibrium was proven in some intraductal and intralobular proliferation and is significantly increased into in situ carcinomas and atypical hyperplasia, compared with usual hyperplasia (6). Increased hormonal contents, as those observed in the case of premenopausal women or those breastfeeding are associated with a reduced number of ER+ epithelial cells, while the reduced circulatory concentrations of estrogens, as those observed in the case of postmenopausal women, are associated with an increased number of positive ER cells. In normal mammary tissue, the percentage of positive ER cells grows with the age, correlated with the diminished plasmatic concentration of the circulatory steroid hormones. In the case of premalignant proliferative lesions, as well as in the case of the in situ carcinomas, this negative association is lost, being a display of the early molecular changes that appear in the neoplastic transformation (7). The relatively elevated risk of developing a carcinoma was associated with the sclerosing adenosis lesions, intraductal florid papiloma, fibroadenoma, phyllodes tumor, fibrocystic disease with proliferative lesions adenosis-type and ductal hyperplasia. Some histopathological changes, such as apocrine metaplasia and ductal ectasia were not associated with an increased risk of developing mammary cancer. The evaluation of hormonal receptors presence in benign lesions is necessary in order to evaluate the opportunity of chemotherapy, with a positive ratio cost – benefit.

Clinical studies revealed a relationship between some histological types of benign mammary lesions and the risk of developing breast cancer, in accordance with the histological type of lesion and the hormonal status (8, 9, 10). The associated risk for the histological factors is the same for both breasts, suggesting that those markers must be regarded into a general context rather than as simple predecessor factors, depending on the histological type of lesion. There is also an interaction between the histological risk factors and the estrogen hormones in order to determine the level of associated risk. According to some studies, tamoxifen has diminished by over 86% the risk of mammary cancer in the case of a subset of female patients, diagnosed with atypical

ductal hyperplasia, suggesting the utility of the antiesteogenic therapy, especially in the case of a high risk group of female patients (11). Although there are disagreements, it is well known that small dimension tumors, in the early stage, cannot be detected using mammography (12, 13, 14).

Within the benign lesions studied, ER are expressed in 25.3% and PR in 33% of the cases. Non-malignant proliferative lesions with an increased risk of developing mammary cancer presented a positive reaction for the estrogen and progesterone receptors. Thus, atypical ductal hyperplasia, with a 5 times higher risk, presented positive ER in 33% of the cases and PR positive in 50% of the cases, with the most frequent phenotype being ER-/PR+. The sclerosing adenosis lesions, characterized by the proliferation of an epithelial and mioepithelial group of cells distorted by abundant fibrous tissue, with a 3 times higher risk of developing mammary cancer presented the highest number of positive cases for estrogen receptors (72%) and progesterone (64%), with most of the cases (45%) being ER+/PR+. In the case of fibroadenomas, estrogen receptors were present in 31% of the cases, PR in 56% of the cases, with ER-/PR+ as the most frequent phenotype (31%). The Phyllodes tumor with malign area changes, which we have encountered accompanying a fibroadenoma, preserved the progesterone receptors positive status for ER and PR and presented a reduced or moderate level of expression (2+), especially for PR. Non – proliferative lesions which were not a diagnose on their own, but were encountered in the case of fibrocystic disease , with a lower risk of developing a carcinoma , did not present a positive reaction for both estrogen and progesterone receptors (15,16,17). All cystic dilatations, either small or large, with a flattened epithelium were negative for the investigated markers (ER-/PR-). In the same manner the apocrine metaplasia lesions were ER/PR negative in all cases.

CONCLUSIONS

Regarding the benign lesions in our study, ER are expressed in 25.3% and PR in 33% of the cases. The proliferative lesions, especially sclerosing adenosis, atypical hyperplasia, florid hyperplasia and papiloma were expressed as ER and PR. The sclerosing adenosis presented most frequent ER (73%) and PR (64%). With the exception of adenosis, which expressed more frequently estrogenic receptors, in the other cases, PR presented a higher expression level. Fibroadenomas revealed PR in 56% cases and ER in 31% of the cases. The Phyllodes tumors expressed only PR. Cystic dilatations and apocrine metaplasia did not express ER/PR. The progesterone receptor prevalence in most of these cases proves a progesterone insufficiency which supports the hormonal disequilibrium theory in tumoral transformation and explains the hormonal therapy success in fibrocystic disease with proliferative lesions. The further study of the hormonal spectrum of those lesions, considered as pre-malignant, may lead to the identification of some groups of hyperplastic lesions, presenting a high risk for developing a mammary cancer and may contribute to the selection of a female patients group requiring a careful observation who might benefit from an of antiproliferative and antiestrogenic treatment.

EXPERIMENTAL STUDY REGARDING THE CHANGES IN THE MEDIAN SAGITTAL SUTURE POST DISJUNCTION ON COMMON RABBIT BREED (Abstract): Widening of the upper jaw by undoing the median suture is a relatively common clinical procedure and the histological studies on sutural tissues, both immediately after disjunction and post disjunction are relatively rare. The present research aims to study cellular changes caused after undoing the median maxillary suture, on a strain of common rabbit breed, in an attempt to prove that the purpose of this therapeutic technique is obtaining neoformed osseous tissue, as a guarantee of the stability of orthodontic treatment results. Of course, changes in rabbit desmale tissues cannot be fully assimilated to the human ones. **Key words:** DISJUNCTION, MEDIAN SAGITTAL SUTURE, NEOFORMED OSSEOUS TISSUE

Intermaxillary disjunction is defined as the undoing of the median palatine suture by means of orthopedic forces. Thus, we obtain dimensional expansion of the upper jaw in transverse direction. According to Boboc (1) "intermaxillary disjunction provides the opportunity to obtain significant widening of the upper arch, the palate, the nasal cavities and even the face in a short period of time".

MATERIAL AND METHODS

The disjunction technique involves two essential features, namely: firm anchorage on the side areas, as well as using a disjunction appliance able to support the effort of "fracture" of the upper jaw.

To this end, two metal trays were made by the size of the rodent's side areas, on a dry skull, which allowed, on one hand, to obtain a working model easy to use, as well as imprinting in order to fabricate the disjunctor.

Given that the experimental rabbits were part of the same strain, individual changes in the side areas proved minimal (common breed rabbits have had the average weight of 2700 g and a dental formula represented by four incisors, six premolars and 6 molars, fully erupted). In order to individualize the contact between the metal trays and the dental area, there were applied retentions in

trays, which were secured on the side areas by means of an autopolimerisable composite material. Thus, the appliances made could be used throughout the batch of rabbits studied, but also in some cases, reused in experimental animals.

For disjunction, a Dentaurum screw was used, with parallel expansion, whose arms were welded to the metal trays (fig. 1).

Fig. 1. The disjunctor – a Dentaurum screw was used, whose arms were welded to the metallic trays

The appliance was tested on a rabbit jaw euthanized beforehand, to observe its effectiveness and to correct the position of the screw from the arch and from the direction of disjunction.

The disjunctors were applied on a number of 10 rabbits (using batches of three rabbits each and a witness rabbit). General anesthesia was administered, using neuroleptanalgesia, namely *Acepromazine* 0.4 mg/kg body weight (BW) and *Ketamine* 0.5mg/kg body weight (BW). The rabbit used as witness was euthanized without cementing its disjunctor. In nine rabbits, the disjunctors were cemented on the premolars and the molars of the upper arch, on one side and the other of the median line, with an autopolimerisable composite material (*Structur 2, Voco,* Germany) (fig.2).

Then, the disjunctors were activated during a single session (ultra-rapid disjunction). The first batch of rabbits was euthanized immediately after cementing and activating the appliances, the second batch after 7 days and the third batch after 14 days.

For histological analysis, the median suture was dissected and sections from all 10 rabbits were prepared, after euthanasia (the witness, batch 1 during activation, batch 2 after 7 days and also batch 3 after 14 days). 10% buffered formalin was used for each part, as mounting medium. Decalcification solutions based on formic acid were used. The material was processed by classical technique of paraffin embedding, with sections cut in 4 microns. Staining used was Haematoxylin-eosin. The microscope used was Olympus BX50, Ocular x10, x20 and x40 (the histopathologic examination was achieved at Clinical Hospital of Orthopedics-Trauma and Osteoarticular TBC).

Fig. 2. The disjunctor was anchored on the side areas by means of the autopolimerisable composite material

RESULTS AND DISCUSSION

It was noticed that orthopedic forces developed by the disjunction appliance have resulted in undoing the median sagittal suture, leading to the beginning of a process of tisular reparation (2), which is completed by forming a new bone. Stadialization of these structural changes, depending on the moment when the batches of animals are sacrificed, is well defined in terms of tisular reorganization (3, 4).

Thus, in the witness rabbit (without disjunctor applied), the median suture presents lamellar osseous tissue (mature), Haversian type and trabecular with adipose marrow, the edges of the palatine bones in the suture area being in direct contact with a thin layer of fibrous tissue (fig. 3).

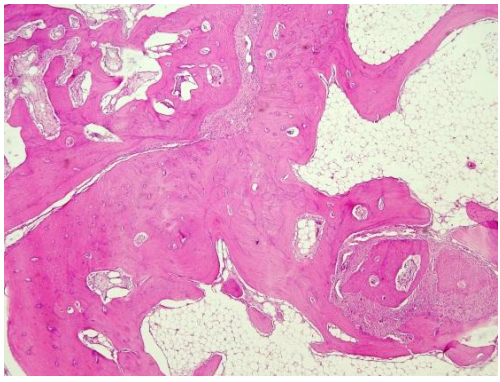

Fig. 3. Median suture in the witness rabbit with lamellar osseous tissue, Haversian type and trabecular

Sections from different levels of the osseous parts removed from the first batch of rabbits, immediately after disjunction, presenting the characteristic aspect of fragmented osseous tissue and hemorrhagic suffusions, as well as polymorphous inflammatory infiltrate (fig. 4).

In sections resulted from the osseous parts removed from the rabbits in the second batch of study (at an interval of 7 days after disjunction), we can observe a stromal cell reaction, with an increased number of fibroblasts (fig. 5), as well as an appositional ossification, through a process of osseous metaplasia in the presence of active osteoblasts increased in size which mark the limits of the osseous matrix (fig. 6). This phenomenon can also be observed in the vicinity of the periodontal ligament (fig. 7).

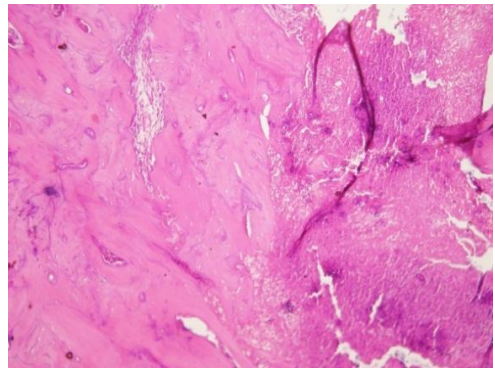

Fig. 4. Cortical bone with area where the osseous tissue is fragmented Hemorrhagic suffusions and polymorphous inflammatory infiltrate are being associated

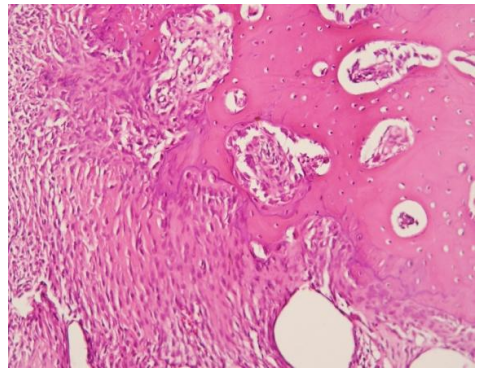

Fig. 5. Mesenchymal tissue with a tendency to densify itself in contact with the osseous tissue

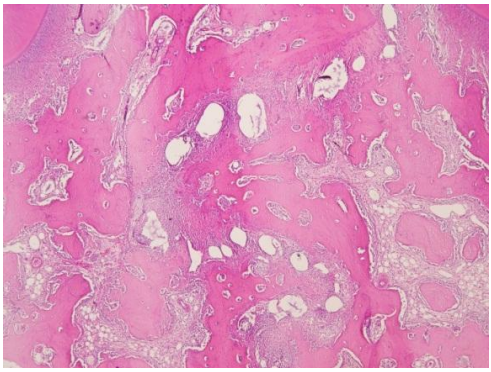

Fig. 6. Appositional ossification – process of osseous metaplasia in the presence of active osteoblasts

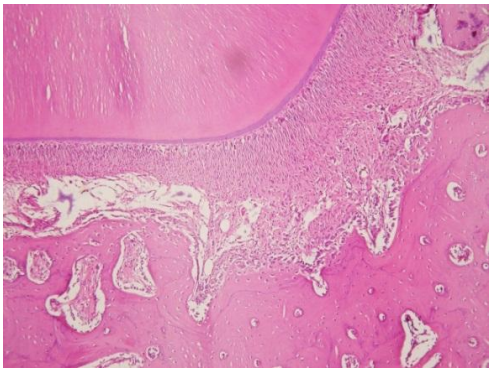

Fig. 7. Appositional ossification is also found in the vicinity of the periodontal ligament

In contrast to the tendency of ossification, in figure 8, are captured osteoclasts responsible for the resorptive osseous processes. The aspect of ischemic necrosis with cracks in the compact bone is associated with centers of osteoclastic activity, which resorb the necrotic bone, associated with elements of simultaneous appositional ossification.

The predominant osteoformative activity following the osteoclastic wave, with cellular dense mesenchymal tissue and in the presence of highly active osteoblasts in contact with the lamellar bone where the primitive bone is formed, as a result of the microfractures that occurred after traction (fig. 9).

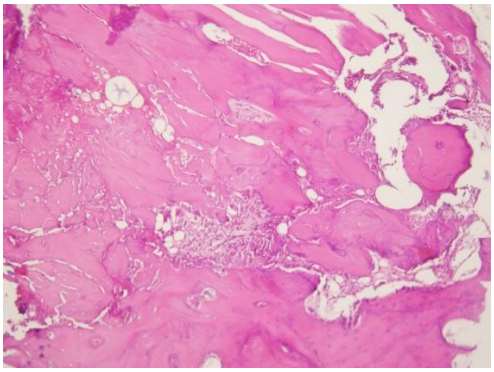

Fig. 8. Ossification is counterbalanced by a process of osseous resorption with the involvement of the osteoclasts

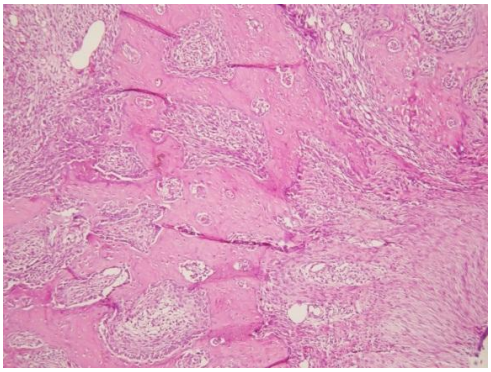

Fig. 9. Predominant osteoformative activity in the presence of the mesenchymal tissue, as well as the osteoblasts found in the vicinity of the lamellar bone

In the third batch of rabbits, sacrificed at 14 days after the disjunction, we detect fragments of cortical bone with appositional ossification (fig. 10).

In the next image, we observe that the suture clearly tends to close itself by forming neoformed osseous tissue (fig. 11). The presence of the immature non-lamellar bone is indicated on the side slopes of the

crack, as well as the presence of the osteocytes in the mature lamellar bone.

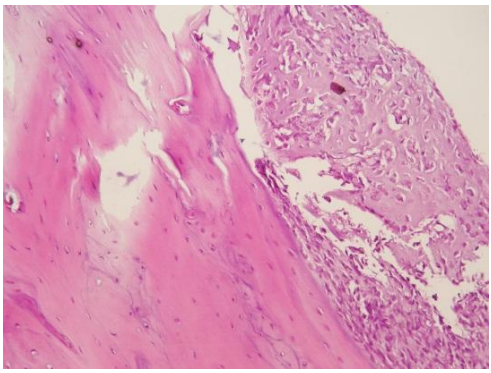

Fig. 10. The area of appositional ossification with uncalcified osteoid matrix and young cortical bone

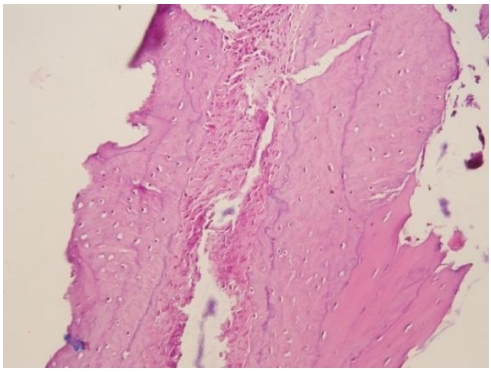

Fig. 11. The tendency of the crack in the area of the median suture to close itself by the process of ossification

CONCLUSIONS

The neoformed bone is made of a substrate particularly favorable for dental movement, allowing the development of the processes of resorption and apposition, the cornerstone of any orthodontic treatment using fixed techniques.

According to the succession of the levels studied in the experiment presented on laboratory animals, we notice that the process of ossification clearly tends to cover the dehiscent palatal median suture area; we must put on hold the fact that the results of our study are not directly transferable to the human tissue.

Rapid and ultra-rapid activation remains an accessible technique and, most of the time, after increasing the diameters, the treatment is suitable to be continued with fixed appliance.

As a consequence, osseous structural changes obtained after disjunction demonstrate mainly that this therapeutic method is useful in situations where the lack of space in the maxillary is important, the reparatory processes taking place and forming new osseous tissue, thus getting a permanent character. In this way, the premises of a much more judicious distribution of teeth are created, in terms of a lower biological sacrifice, offering an additional guarantee for maintaining the stability of the result of the orthodontic treatment.

REFLECTIONS ON FERTILITY DYNAMICS IN ROMANIA (Abstract): **Aims** to highlight the changes occurred in the evolution of the fertility phenomenon in Romania, focusing on developments in the general fertility rate, total fertility rate, number of live births, and on the construction of specific indicators to reveal the source of demographic change. Several theories on the factors that may cause fertility decline it were outlined, underlining the presence of these factors during fertility dynamics in our country. After 1990, population decline may be explained by a close inter-relationship between economic theories (worsening economic conditions lead to decreased fertility) and the second demographic transition (postponement of births, fertility change model). **Key words:** DEMOGRAPHIC CHANGE, FERTILITY, ECONOMIC FACTORS, THE SECOND DEMOGRAPHIC TRANSITION.

Demographic changes have profound implications on future economic and social development of a population (1). While the rise of the life expectancy is considered to be a major achievement for the European Community, decline of birth rates, fertility (tab. I) and its consequences - an aging population - are challenges which the European Union must deal with (2).

RO	-	4,48	3,97	

It is considered that all European Union countries (EU) will face in the coming years an increasing proportion of the total elderly population and a declining proportion of people from active age groups and capable of working (3). Thus, according to data from the European Commission's 2008 demographic report, since 2008 the number of people aged over 60 will increase by about 2 million people every year for a period of 25 years. (4).

In the context of a rising interest about the demographic development of the EU, discussions on the implications of demographic change have increased in number and seriousness in Europe.

Even if there are common issues and common demographic conditions (5) - reducing the number of live births, fewer marriages, rise of the average age of marriage (6) - throughout all Europe, what it is primarily needed is to understand the circumstances and specific national circum-

stances and then to identify the possible solutions to be applied in other countries where there are different contexts. Romania, as a member of the European Union, it is not an exception in terms of population trends.

Given the European context, it is required in Romania to be paid attention to reflect accurate demographic changes. This paper aims to assess the phenomenon of fertility trends in the population of Romania from 1965 until 2007. Through this research it is desired to be observed the specific conditions of our country in terms of demographic change.

In 2007, the large generation of 1967 (so-called generation of "decrees") has reached 40 years, women of this generation's contribution to the phenomenon of fertility is decreasing as magnitude and consequently, in importance. In this paper, wanting to surprise the moment when the influence of large generations born in the communist period has begins to recede, we stopped with the analysis in 2007.

As the objectives of the present research, we aimed to document changes in the number of live births over the period 1965-2007 and to determine the influence that the alteration of specific group-age fertility rates had it on the population.

MATERIAL AND METHODS

The present research is a descriptive transversal study on the phenomenon of fertility in the female population of childbearing age in Romania (7, 8).

To describe the evolution of the fertility phenomenon in Romania it was set up a database containing the following data as follows: number of live births in calendar years, the number of live births by mother's age group by calendar year, the number of women of childbearing age groups quinquennial age, in calendar years. Subsequently, usual indicators were constructed, as the general fertility rate, total fertility rate, but, also, less used indicators such as ratio of the live births born in two different calendar years (years used for comparison), the difference between the number of live births born in two different calendar years (years used for comparison) and the difference between number of live births born in year 0 and number of live births expected to be born in year 0 (based on the assumption that the fertility in year 1 is applied to population of childbearing age of year 0 - year 0 being the year of comparison, and year 1, the reference).

The symbols used to describe how to construct the indicators used in the study are as following:

- $f_x^1 = Age - specific\ fertility\ rate\ for\ age\ x\ , for\ year\ 1$
- $f_x^0 = Age - specific\ fertility\ rate\ for\ age\ x, for\ year\ 0$
- $F_x^1 = number\ of\ women\ of\ childbearing\ age\ for\ age\ group\ x, for\ year\ 1$
- $F_x^0 = number\ of\ women\ of\ childbearing\ age\ for\ age\ group\ x, for\ year\ 0$
- $g_x^1 = number\ of\ live\ births, for\ year\ 1$
- $g_x^0 = number\ of\ live\ births, for\ year\ 0$

The indicators build and used in the research are as following:

1. The ratio between the numbers of live births during the two years of reference

$$I_{N1/0} = \frac{\sum_{x=15}^{49} f_x^1 F_x^1}{\sum_{x=15}^{49} f_x^0 F_x^0}$$

2. The difference in absolute number of live births between the two years of refer-

ence $\Delta_{N1/0} = \sum_{x=15}^{49} f_x^1 F_x^1 - \sum_{x=15}^{49} f_x^0 F_x^0$

3. The ratio of fertility between the two years of reference

$$I_{N_{1/0}}^{fg} = \frac{f_g^1}{f_g^0} = \frac{\sum_{x=15}^{49} f_x^1 F_x^1}{\sum_{x=15}^{49} F_x^1} \div \frac{\sum_{x=15}^{49} f_x^0 F_x^0}{\sum_{x=15}^{49} F_x^0} = \frac{\sum_{x=15}^{49} f_x^1 g_x^1}{\sum_{x=15}^{49} g_x^0}$$

4. The difference between live births in year 0 and expected live births in year 0, if it is applied fertility of the female childbearing age population from year 1 to the female childbearing age population from year 0

$$\Delta_{N_{1/0}}^{fg} = \left(f_g^1 - f_g^0\right) \sum_{x=15}^{49} F_x^1$$

RESULTS

Romania is experiencing today an unprecedented number of demographic changes in the demographic history of the last century, changes that lead to an aging population (8). The most important factors leading rapidly to an aging population are: persistently maintaining the fertility rates at a very low level, increased life expectancy and the transition of generations born in the communist period to the retirement period. Below are captured, in a succinct picture, the trends of fertility phenomenon during 1965-2007 and their demographic consequences at the population level.

1. Evolution of General Fertility Rate in Romania

General Fertility Rate (number of live births per 1,000 women of childbearing age) had a downward trend since 1991. The downward trend in the General Fertility Rate between years 1956 - 1965, led to the political decision to take action in order to rectify the situation. In the period 1956 - 1965 in terms of legislation, it was permissible to make abortion on demand, in the context of the communist ideology of the time when it was encouraged female labor force participation, and women were regarded as an important work force for the economy. In 1966, the government at that moment decided to ban abortion on demand by Decree 770/1966, decree which came into force in October the same year (9). The consequence was that General fertility rate reached a value of 105.5 live births per 1,000 women of childbearing age in 1967; starting next year, it began to decline more or less sharply depending on the coercive measures applied in different moments by the communist authorities of the time. Thus, the lowest values of the General fertility rate in the communist period were recorded in years 1966 (55.7 $‰_0$), in 1973 (70.4$‰_0$) and 1983 (59.5$‰_0$), followed by consecutive years of increases in values. From the sociological perspective, the effects of Decree 770/1996 decreased gradually during time, even if the authorities have introduced ever more repressive measure. In addition to legal provisions, the period 1980-1989 was characterized by the lack of availability of contraceptive measures, but also by the deterioration of living conditions of the population. The downward trend in the General Fertility Rate has widened since 1990. On 26 December 1989, the National Salvation Front Council -the revolutionary power at that time- issued the Decree Law No. 1, through which were repealed several laws and, decrees. One of the acts that were repealed it was the Decree 770/1966 on the prohibition of abortion (10), (11). From an economic perspective, the first period after 1990 is characterized by strong fluctuations in the rate of inflation (in 1991, the average monthly rate of inflation - the average monthly price increases - was 10.3%, for

1993 to reach 12.1%) (11).

2. Model of Age-Specific Fertility Rate: Evolution

In addition to the downward evolution of the General Fertility Rate, fertility rates specific by age groups followed the same trend. The new model of fertility suggests the change of the fertility pattern from an early one, where the highest fertility rate is recorded at specific age group 20-24 years, to a late fertility model, a model where the highest rate of fertility is recorded at the age groups of 25-29 years.

3. Evolution of Total Fertility Rate

During the period of observation, total fertility rate went from a level of 2.9 children per woman in 1956. Registration for two consecutive years a total fertility rate values below the "replacement" level- that is 1.9 children per woman- led to the Government intervention to take the coercive measures mentioned above.

Following the implementation of pronatalist policies, in 1967 it was recorded a level of 3.7 children per woman. Peak level of 1967 has not been recorded in subsequent years; in 1968 the value registered being 3.6 children per woman, the evolution being still downward. After 1990, total fertility rate has continued to decrease, however, the trend becoming very sharp: the value of 1.8 children per woman in 1990 will reach a level of 1.3 children per woman in 1995 (fig. 1).

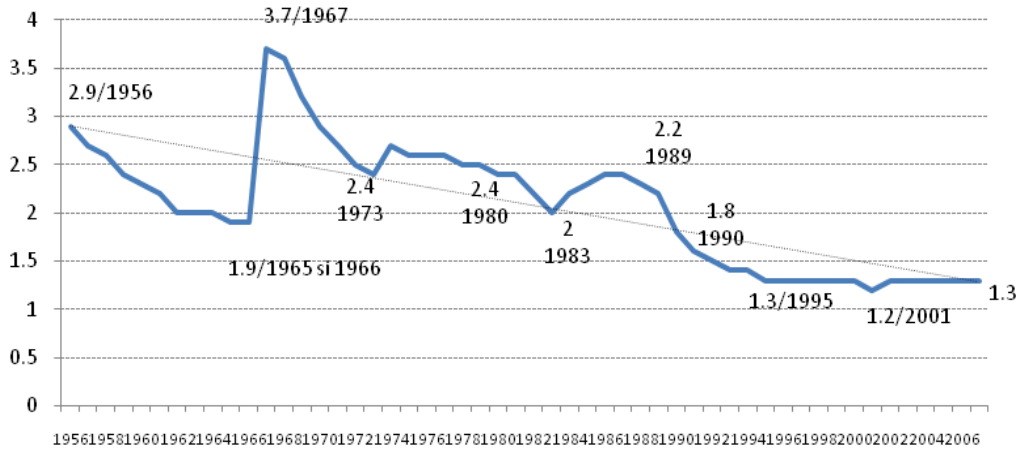

Fig. 1. The evolution of total fertility rate, Romania, during 1956-2007

Highlighting the demographic losses

Number of live births

Evolution of live births had a downward trend since 1967. If this year in Romania the number of live births for the period reached a record level with a value of 527 764 live births, in subsequent years, the downward trend fluctuated; the decrease of the level of the number of live births in 1966 (273,678 live births) 1973 (378696 live births) and 1983 (321 498 live births) have lead to coercive measures that had therefore increased the number of live births in consecutive years. Cancellation of legal restrictions regarding abortions on demand in 1990, led in 1991 to recording a

number of live births under the level registered in the year 1965. Downward trend continued until 2007 (fig. 2).

Demographic losses due to lower birth rates and fertility rates are dramatic. Since 1990 is registered a shortage in number of live births from year to year. Comparing the number of live births in 1990 and subsequent years show an annual population loss taking into account as the reference the year 1990. In 2007, the deficit of live births compared to 1990 was 100 018 live births (fig. 3).

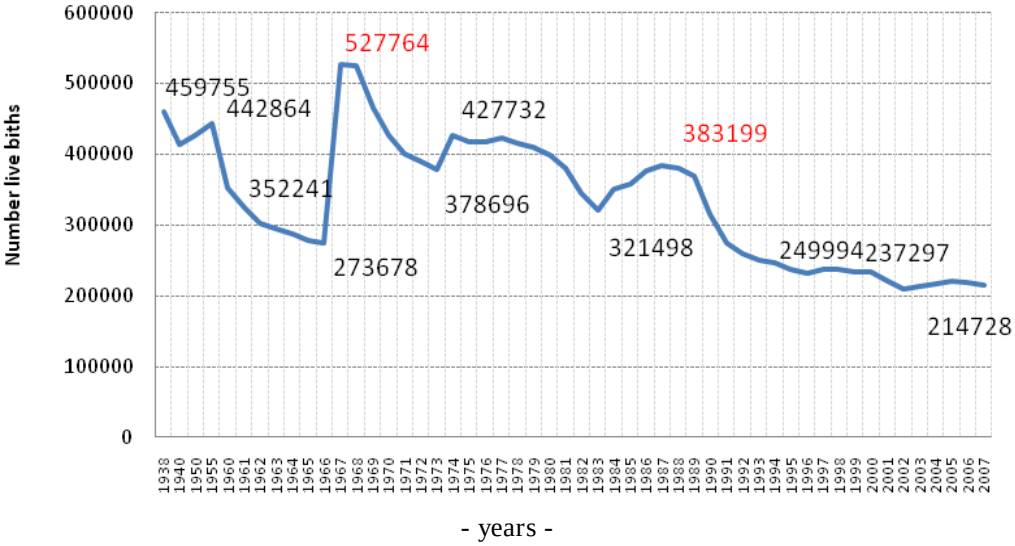

Fig. 2. The evolution of live births in Romania, during 1938-2007

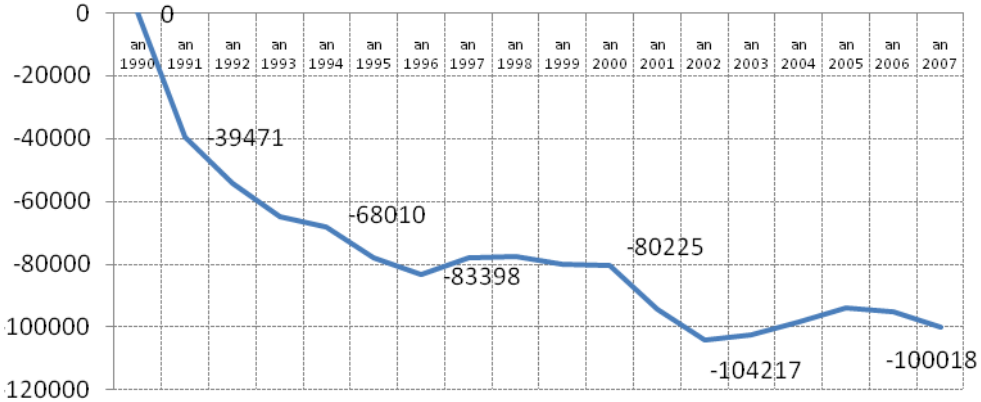

Fig. 3. The evolution of the difference between the number of live births from thee years after 1990 and the live births in 1990, Romania, 1990-2007

Comparison of the number of live births recorded in the consecutive years of 1990 and the number of live births registered in 1990 has as result a deficit every year since 1990. This deficit reached a record value of 30% in 2007 compared to 1990 (fig. 4).

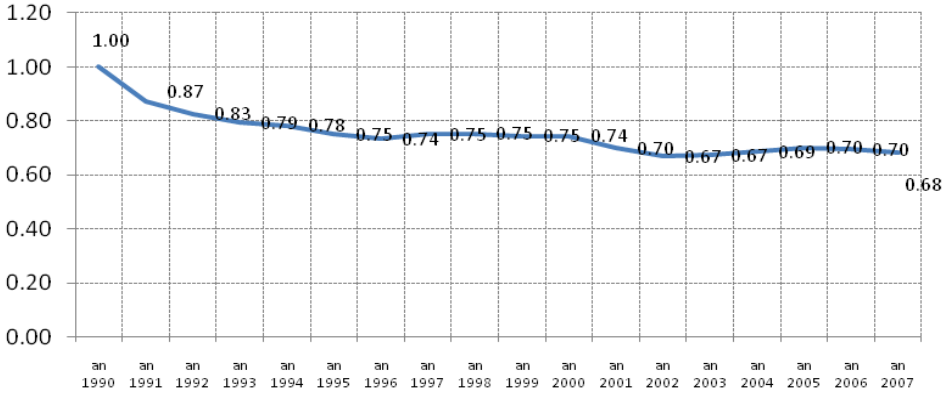

Fig. 4. The evolution of the ratio of live births of the years after 1990 and the live births in 1990, Romania, 1990-2007

5. Quantifying the influence of decreasing General Fertility Rate on the number of live births

If the General Fertility Rate in 1990 would be retained for each subsequent year, the number of live births expected in these circumstances would have been higher than the level actually recorded. Applying the General Fertility Rate from 1990 to the real number of female population of childbearing age recorded for each subsequent year of 1990 lead to a highlighting of the live births' deficit due to the general rate of fertility decline. The number of live births in 2007, while maintaining the General Fertility Rate in 1990, would have been 309 291 live births from 214 158 live births actually registered, which means that while preserving the general rate of fertility 1990, in 2007 a number of 95033 live births it would be born in addition to the actual observed number. This difference of 95 033 live births between the number of actual (observed) live births in 2007 and the expected level while maintaining General Fertility Rate from 1990, is quantifying the decrease of the number of live births due to influence of General Fertility Rate on the number of live births (fig. 5).

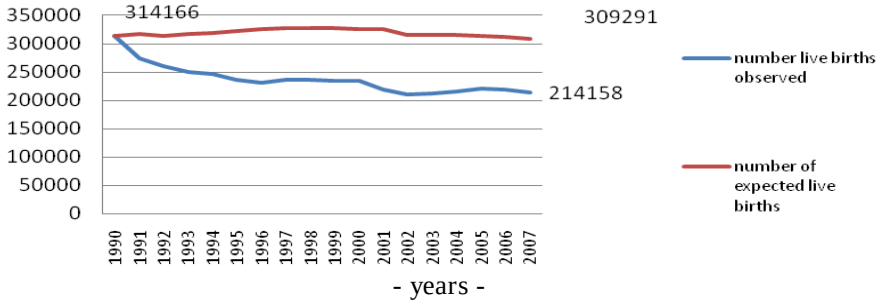

Fig. 5. The evolution of the number of live births observed and expected number of live births if the general rate of fertility would be preserved at the level of year 1990, Romania, 1990-2007

DISCUSSION AND CONCLUSIONS

Fertility decline is a phenomenon that has affected and affects not only our country but is known at European level (12). The decline of fertility is due to a networking and an interaction of many factors, but the evidence suggests that the main factors incriminated are still different from country to country. Thus, changes in fertility trends can be given by the second demographic transition, by delaying the moment of birth or may be the population reaction to the economic crisis (13, 14). Data from the literature suggests that worsening economic conditions contribute to decreased fertility (15), however, is difficult to prove directly, the population decline is due to which factor. For Romania it is possible that each of them to be contributed, albeit at different moments of time. Thus, immediately after the 1989 revolution, it is possible that the main factors that led to the decline in fertility to be economic ones (16), but in close relation to contraceptive policies. Immediately after the change of political regime in 1989, the laws that prohibited abortion on demand have been eliminated and economic conditions have become precarious. Not only macro-economic climate has become unstable, uncertain, but poverty has affected millions of people around the Eastern European region (17).

In Romania, during 1990-2007, the deficit of live births increased, reaching in 2007 to register 100,018 fewer live births from 1990, a decline of 30%. In addition, if the General Fertility Rate from 1990 it would being kept, the number of live births that it would have been registered in 2007 it was 309,291 as against 214,158 who had been actually registered. Registration of this deficit cannot be apart to the worsening economic conditions, as previously mentioned. The relationship between fertility phenomenon and economic conditions, family services and related policies has been supported by other researchers, which stated that the loss of resources in Eastern European countries where the political system was changed in 1980 drew to an increased decline of fertility (18).

For Romania, to the records of the influence of the phenomenon of economic elements, elements of the second demographic transition are added, probably from the 2000s. Specific sides of the second demographic transition would be the postponing of the timing for family formation, delaying their first birth, the growth of consensual unions and cohabitation instead of marriage and increasing the number of children born outside marriage. All these explanations have been events that led to the decline of fertility in Romania during the 2000s. The couple's fertility history from our country is changing (level of education of those who are starting a family, the trajectories of mental and physical health of family members, other aspects of the life course), all having their impact and their influence on fertility trends.

In this work we wanted to capture the moment when the quota of contributions of the numerous fertile generation of year 1967 begins to diminish. The female fertile population is still numerous, at the moment, being composed of numerous large generations of women born in the communist period, but changes are foreseen to begin on age structure of this population. For the future, these changes suffered by the female population of childbearing age and their influence on the fertility trend and on the actual number of live births must be taken into consideration.

ASSESSMENT OF SOME BYOPHYSICAL PARAMETERS OF HUMAN ERYTHROCYTE BY FT-IR SPECTROSCOPY – PRELIMINARY STUDY (Abstract): Based on the biochemical composition of erythrocyte membrane and asymmetric distribution of phospholipids, proteins, and cholesterol, FT-IR spectroscopy can monitor the distribution and interaction pattern of membrane constituents. **Material and methods:** The study series included 21 clinically healthy subjects aged between 20 and 60 years. Complete blood counts were performed and the serum biochemical compounds (cholesterol, triglycerides, total protein, glucose) were determined. **Results and discussions:** The parameters that can be assessed by erythrocyte FT-IR in relation with the biochemical factors that may influence membrane fluidity are: degree of fatty acids unsaturation, saturated fatty acids/unsaturated fatty acids ratio, cholesterol/phospholipids ratio, and phospholipids/protein ratio. Based on the obtained results, in the assessment of membrane status the following vibration modes were selected as spectral parameters: vibration associated valence bond (=CH), asymmetric valence CH_2 groups, modes associated with P=O bond and amine bands I and II specific for proteins. Other parameters, such as ν(C-O) specific to glucose, may provide additional information on glucose metabolic status. **Conclusions:** By correlating biochemical markers with these spectral parameters information on red cell membrane status, status that may reflect different pathological processes, can be obtained. **Key words:** ERYTHROCYTE, BLOOD BIOCHEMICAL PARAMETERS, FT-IR SPECTROSCOPY, MEMBRANE FLUIDITY

Studiul membranei celulare folosind spectroscopia FT-IR este o metodă relativ recent introdusă în studiul sistemelor biologice. Pentru studiul statusului membranar plasmatic se poate alege ca model membrana eritrocitară din mai multe considerente: disponibilitate în număr mare a globulelor roşii, obţinerea probelor de studiu este relativ simplă, este un model membranar recunoscut şi se pot face corelaţii cu alţi parametri hematologici în contextul fiziologic sau patologic dat (1).

Plecând de la compoziţia biochimică a membranei eritrocitului şi distribuţia asimetrică a fosfolipidelor, proteinelor şi colesterolului, se poate urmări prin spectroscopie FT-IR distribuţia şi modul de interacţiune a componentelor membranare, putându-se pune, indirect, în evidenţă aspectul de mozaic fluid membranar. În funcţie de compoziţia biochimică, membranele biologice, inclusiv cea eritrocitară, sunt caracte-

rizate de diferiţi parametri biochimici sau biofizici. Astfel, studii recente prin spectroscopie FT-IR, au subliniat modificările induse de stresul mecanic sau biochimic ca fiind un inductor patologic (2). Stresul oxidativ, prin intermediul radicalilor liberi, atât la nivel celular cât şi extracelular induce modificări ale membranei eritrocitare (3).

Aspectul spectral al eritrocitului urmăreşte în domeniul 4000-400 cm^{-1} frecvenţele de absorbţie ale grupărilor caracteristice fosfolipidelor membranare (4, 5), colesterolului şi proteinelor eritrocitare (5).

TABELUL I

Grupele funcţionale majore ale membranei eritrocitare şi absorbţiile IR caracteristice (5)

Numărul de unda (cm^{-1})	**Atribuirea benzii de absorbţie**
3020-3000	ν(=CH): acizi graşi nesaturaţi, esteri colesterolici
2990-2950	$\nu_{as}(CH_3)$: fosfofolipide,esteri colesterolici, acizi graşi
2950-2880	$\nu_{as}(CH_2)$: fosfolipide, lanţuri lungi ale acizilor graşi
2880-2860	$\nu_{s}(CH_3)$: acizi graşi, fosfolipide
2870-2830	$\nu_{s}(CH_2)$: fosfolipide, lanţ lung acizi graşi
2996-2795	$\nu_{s}(CH_3)$, $\nu_{as}(CH_3)$, $\nu_{as}(CH_2)$, $\nu_{s}(CH_2)$: acizi graşi, fosfolipide
1739-1713	ν(C=O): fosfolipide, esteri colesterolici, gliceride
1713-1589	ν(C=O): (amida I) lanţ proteină β
1589-1474	δ(N-H): (amida II)lanţ proteină α

MATERIAL ŞI METODĂ

Ne-am propus căutarea unor corelaţii între parametrii biochimici sangvini, vârstă şi parametrii spectrali FT-IR ai membranei eritrocitare. Scopul studiului este de a stabili în ce măsură informaţiile obţinute prin analiză spectrală FT-IR a membranei eritrocitare pot fi puse în relaţie cu statusul fiziologic sau patologic al pacientului.

Subiecţi

Studiul prezentat este unul preliminar, în vederea identificării parametrilor spectrali membranari eritrocitari care pot fi corelaţi cu diferiţi parametri biochimici sanguini. Lotul este format din 21 subiecţi cu vârsta cuprinsă între 20-60 ani (6 bărbaţi, 15 femei), clinic sănătoşi, pentru care s-a efectuat hemoleucograma analitică (număr hematii, număr leucocite, hematocrit (Hct) hemoglobină (Hb), volum mediu eritrocitar (MCV), hemglobina medie eritrocitară (HEM), număr trombocite) şi la care s-au dozat compuşi biochimici serici: colesterolul plasmatic, trigliceridele plasmatice, proteine totale, glicemia.

Material

Pentru hemoleucogramă s-a utilizat Analizatorul automat ABXP60-RO, iar

pentru biochimia serică Analizatorul automat SLIM-RO.

Pentru analiza prin spectroscopie FT-IR s-au utilizat aceleaşi probe de sânge din care s-a realizat hemoleucograma (sânge venos recoltat dimineaţa, *à jeun* în vacutainere de 5 ml cu 10mM Na_4EDTA).

Metodă

Probele au fost pregătite pentru a fi studiate prin spectroscopie FT-IR la un interval de 6 ore de la recoltare, timp în care au stat la frigider la 4˚C.

Probele s-au centrifugat 5 minute la 1000g, după care s-au separat de plasmă prin aspirarea surpernatantului.

Eritrocitele rămase s-au spălat pentru a elimina resturile de plasmă, prin centrifugare de 3 ori la 1500 g cu soluţie izotonă de soluţie NaCl 0.9 % în raport de 1:1, după care s-au realizat diluţii de eritrocite spălate: soluţie NaCl 0.9 % în raport de 1:19 (5). Probele eritrocitare au fost apoi analizate prin spectroscopie FT-IR prin realizarea unor pelicule plasmatice, respectiv eritrocitare, realizate din 5 µl probă, pe suport de KRS-5, prin uscare în vid (5 mm Hg la 20˚C) (5, 6). Fiecare probă a fost analizată in triplicat, pentru a urmări reproductibilitatea rezultatelor, iar pentru analiza statistică s-a utilizat spectrul probelor cel mai bine uscate (în funcţie de picurile de absorbţie caracteristice). Probele s-au înregistrat în transmisie, cu un spectrometru FT-IR Bruker Vertex 70. Domeniul de lungimi de undă: 4000 – 400 cm^{-1}. Fiecare probă a fost înregistrată prin acumularea a 32 de spectre, cu rezoluţie de 2,0 cm^{-1}.

REZULTATE

Analiza membranei eritrocitare prin FT-IR, în funcţie de factorii biochimici care pot influenţa fluiditatea membranei, permite urmărirea următorilor parametri eritrocitari: gradul de nesaturare al acizilor graşi, raportul acizi graşi saturaţi/acizi graşi nesaturaţi, raportul colesterol/fosfolipide, raport fosfolipide/proteine (7). Se mai pot urmări nivelul glucozei şi al lactatului la nivel eritrocitar, marker al activităţii metabolice eritrocitare.

S-a observat o corelare invers proporţională între volumul mediu eritrocitar (MCV) şi gradul de nesaturare al eritrocitelor. Pentru estimarea numărului de legături olefinice raportate la lanţurile acil ale acizilor graşi eritrocitari am raportat aria specifică ν(=CH) la aria$\nu_{as}(CH_2)$ (fig. 1) după un model din literatură (8, 9).

Vibraţiile de valenţă simetrică specifice legăturii $\nu_s(CH_2)$, precum si cele ale grupei υ(P=O) sunt specifice fosfolipidelor. Scăderea ariei pentru $\nu_s(CH_2)$ şi ν(P=O) este corelată cu creşterea gradului de rigiditate a membranei (10). Creşterea rigidităţii membranei se corelează cu concentraţia de colesterol plasmatic în acord cu datele din literatură (7) (fig. 2).

Măsurătorile noastre au fost efectuate la temperatura constantă de 22°C, valoarea medie pentru $\nu_s(CH_2)$ fiind de 2871,277 cm^{-1} şi o valoare pentru deviaţia standard σ = 0,306. Se poate stabili o corelare între abaterea faţă de medie pentru $\nu_s(CH_2)$ şi valorile concentraţiei pentru colesterolul plasmatic, respectiv trigliceridele plasmatice (fig. 4**).**

Proteinele au ca parametri specifici spectrali banda amida I (determinată, în principal, de vibraţia de valenţă a grupei C=O), aflată în domeniul 1695-1574 cm^{-1}, şi banda amidă II (combinaţie de deformaţie N-H şi valenţă C-N), care se observă în domeniul 1574-1471 cm^{-1}.

Un aspect interesant este modul în care se corelează aria specifică glucozei eritrocitare ν(C-O) în domeniul 1062-997 cm^{-1}, cu aria specifică $\nu_s(CH_2)$, ca indicator al mobilităţii moleculare membranare (fig. 6).

DISCUŢII

Acizii graşi nesaturaţi sunt evidenţiaţi spectral prin absorbţiile specifice grupărilor olefinice ν(=CH) în domeniul 3030 – 3004 cm^{-1}. Raportul dintre ariile benzilor din domeniile 2800-3030 caracteristic vibraţiilor grupării CH şi 3030 – 3004 cm^{-1} (8) oferă informaţii referitoare la gradul de nesaturare al lanţurilor de tip acil al acizilor graşi membranari (8, 11). Creşterea ariilor benzii de valenţă olefinică se traduce prin creşterea gradului de nesaturare membranar (8, 9).

Faptul că ariile specifice legăturilor olefinice se corelează cu MCV poate fi expresia statusului fiziologic eritrocitar (fig.1), eliminarea eritrocitului din circulaţie fiind iniţiată de rigidizarea membranei datorită printre altele şi proceselor de oxidare membranară (12, 13). Rigidizarea cât şi creşterea în volum a eritrocitului face ca durata de viaţă a acestuia sa fie una redusă ca urmare a deformabilităţii reduse şi expresiei unor markeri specifici (14).

Modificarea fluidităţii membranare evidenţiată prin absorbţiile asociate CH_2, sau CH_3 simetrice sau asimetrice este în strânsă legătură cu compoziţia mediului extern plasmatic (fig.2) (colesterol, trigliceride, glucoză) (7).

Nucleele sterolice interacţionează cu regiunea lanţurilor hidrocarbonate, fosfolipidice în principal, cea mai apropiată de grupările polare ale capului lipidic, lăsând restul lanţului flexibil. Rezultă astfel o imobilizare parţială a fosfolipidelor pusă în evidenţă prin modul în care se modifică aria specifică $\nu_s(CH_2)$ şi cea a ν(C=O), asociată colesterolului, în domeniul 1739-1702 cm^{-1} (fig. 3). Astfel, putem întări ideea că prezenţa unui anumit procent de colesterol membranar diminuează procentul de fosfolipide care participă la tranziţiile conformaţionale (7), (15).

Asher şi *Levin* (15) au studiat influenţa temperaturii şi a unei cantităţi de colesterol asupra modului de împachetare a lanţurilor alchil din dipalmitoilfosfatidilcolină, urmărind vibraţiile de valenţă simetrică şi asimetrică ale grupelor CH_2. S-a constatat că tranziţia de fază produce o deplasare cu 4 cm^{-1} a $\nu_{as}(CH_2)$, când creşte brusc numărul conformerilor *gauche*. Adăugarea unei cantităţi >20 mol% de colesterol a dus la o tranziţie de fază fără salt de frecvenţă, datorită scăderii mobilităţii lanţului alchilic. Autorii au considerat că modul de împachetare s-a modificat de la unul hexagonal la unul quasi-hexagonal. O deplasare mai mică de frecvenţă a $\nu_{as}(CH_2)$, asociată rigidizării lanţului alchilic, a fost observată de *Rooney şi colab*. (16) în cazul membranelor eritrocitare îmbogăţite în colesterol. Scăderea concentraţiei trigliceridelor plasmatice, cât şi a colesterolului duce la scăderea pantei spectrului, pus în evidenţă prin abaterea faţa de valoare medie în intervalul M±σ (fig.4) Aceste modificări ar putea fi explicate prin prisma adaptării homeovâscoase a membranelor (7).

Raportul fosfolipide/proteine, în favoarea proteinelor**,** are un efect de reducere a difuziunii laterale atât a lipidelor cât şi a proteinelor. Proteinele suferă anumite schimbări de formă pentru a realiza funcţiile specifice. Studiile experimentale asupra vâscozităţii membranare, în funcţie de activitatea proteinelor membranare, sunt dificil de realizat deoarece vâscozitatea membranară poate fi schimbată la temperatură constantă prin schimbarea compoziţiei membranare, schimbări care pot afecta proprietăţile proteinelor prin afectarea interacţiunii lipid-proteină. A apărut astfel o idee conform căreia modificările vâscozităţii membranare ar trebui să afecteze activi-

tatea proteinelor membranare. Pentru susţinerea acestei idei a fost introdusă noţiunea de „adaptare homeovâscoasă", care menţine vâscozitatea membranară la o valoare optimă pentru exprimarea activităţii proteice. Aceasta este probabilă, deoarece studii referitoare la compoziţia fosfolipidică sugerează că modificările de fluiditate constituie un factor semnificativ în privinţa activităţii proteice (1).

Rezultatele obţinute de noi arată o dependenţă liniară a ariilor de vibraţie specifice pentru banda amidă I, respectiv amidă II, faţă de ariile specifice fosfolipidelor $\nu_s(CH_2)$ (fig.5), ceea ce sugerează o scădere a mobilităţii proteinelor în relaţie cu scăderea mobilităţii fosfolipidelor.

CONCLUZII

Studiul FT-IR al membranei eritrocitare a permis o evaluare preliminară a statusului membranar prin aprecierea mişcărilor moleculelor în funcţie de benzile de absorbţie caracteristice componentelor majoritare membranare: fosfolipide, colesterol şi proteine. din cauza eşantionului relativ mic de pacienţi, validarea statistică a rezultatelor obţinute până în prezent nu poate fi realizată. În schimb, rezultatele preliminare au permis alegerea ca parametri spectrali în evaluarea statusului membranar a următoarelor moduri de vibraţie: vibraţia de valenţă asociate legăturii (=CH), cea de valenţă asimetrică a grupelor CH_2; modurile asociate legăturii P=O, precum şi benzile amidă I şi II, specifice proteinelor. De asemenea, urmărirea altor parametri, cum ar fi ν(C-O) specifică glucozei, poate aduce informaţii despre statusul metabolic al eritrocitului.

Corelarea acestor parametri spectrali cu diferiţi markeri biochimici poate oferi informaţii despre statusul membranar eritrocitar, status care poate fi pus în relaţie cu diferite procese patologice.

NOUTĂȚI

NOI MODALITĂȚI DE DIAGNOSTIC ÎN INFECȚIILE CU *KINGELLA KINGAE*

Kingella kingae este frecvent implicată în infecţiile ostearticulare la copil. Deoarece metodele de izolare clasice sunt dificile, s-a încercat standardizarea metodelor de diagnostic prin tehnici de biologie moleculară. În acest scop s-a folosit ca secventă de interes toxina RTX, genomul bacterian nefiind secvenţiat până în prezent. Scopul studiului a fost dezvoltarea unei metode rapide, sensibile şi specifice utilă pentru a stabili diagnosticul etiologic al acestor infecţii. Au fost aplicate două metode Real Time PCR (în sistem Taq Man şi SYBR green), ambele având ca scop indentificarea secvenţelor nulceotidice rtxA. Sensibilitatea şi specificitatea metodelor a fost evaluată folosind 67 tulpini bacteriene (31 au fost *Kingella kingae).* Apoi, 52 probe pozitive şi/sau negative în cultură şi/sau PCR au fost testate folosind aceste două tehnici. Ulterior s-a folosit tehnica PCR "în cuib" şi secvenţierea tulpinilor izolate pentru a confirma prezenţa *Kingella kingae* în probele luate în lucru. Rezultatele obținute au demonstrat acurateţea metodelor mai sus prezentate în stabilirea diagnosticului etiologic. (Lehours P, Freydière A, Richer O et al, The rtxA Toxin Gene of Kingella kingae: a Pertinent Target for Molecular Diagnosis of Osteoarticular Infections. *J Clin Microbiol* 2011; 49: 1245-1250).

CARBAPENEM RESISTANCE IN *KLEBSIELLA PNEUMONIAE* CLINICAL ISOLATES FROM URINARY TRACT INFECTIONS (Abstract): Resistance to carbapenems by KPC (*Klebsiella pneumoniae* carbapenemase) production in *Klebsiella pneumoniae* clinical isolates was first described ten years ago in the USA and recently reported in other countries. This enzyme inactivates all beta-lactam antibiotics and is associated with fluoroquinolone and aminoglycoside resistance. **Material and methods**: We investigated the carbapenem resistance in 498 *Escherichia coli* and *Klebsiella pneumoniae* strains isolated from urinary tract infections during 2009 in the Iasi "Dr. C. I. Parhon" Clinical Hospital. Antimicrobial susceptibility testing was performed according to CLSI guidelines. To detect ESBL (e*xtended spectrum beta-lactamase*) and KPC production we used phenotypic tests and molecular biology methods (PCR). **Results**: From all tested strains, only two *K. pneumoniae* strains showed modified susceptibility to carbapenems. The modified Hodge test was positive for the strain resistant to ertapenem, meropenem, imipenem (K_A) and negative for the strain resistant only to ertapenem (K_B). Both K_A and K_B isolates were negative for bla_{KPC} and bla_{TEM} genes, but harbored bla_{SHV} and $bla_{CTX\text{-}M}$ genes, respectively. **Conclusions**: We report the first carbapenem resistant *K. pneumoniae* strains from Northeast Romania. The resistance is not mediated by KPC-carbapenemase; the possibility of dual mechanisms through cefalosporinases production and porins loss is suggested. **Key words:** *KLEBSIELLA PNEUMONIAE*, CARBAPENEMS, RESISTANCE MECHANISMS

Carbapenemele sunt folosite în special în tratamentul de primă intenție a infecțiilor severe determinate de bacili gram-negativi. Instalarea rezistenței la aceste antibiotice a condus la limitarea opțiunilor terapeutice, asociată cu o rată înaltă de mortalitate. Fenomenul este relativ frecvent întâlnit la bacili gram-negativi nefermentativi (*Pseudomonas aeruginosa, Acinetobacter baumannii*), mai recent fiind raportat în unele zone geografice şi la reprezentanți ai familiei *Enterobacteriaceae*, în special la *Klebsiella pneumoniae* (1).

Acest fenotip de rezistență poate fi explicat prin producerea de carbapenemaze (aparținând claselor moleculare Ambler A, B, D), care inactivează toate β-lactaminele, sau printr-un mecanism dual în care sunt impli-

cate cefalosporinaze (beta-lactamaze cu spectru extins, AmpC) asociate cu reducerea permeabilității membranei externe (pierderea unor porine membranare OmpK35, OmpK36) (2). Raportarea în diferite țări de pe glob a tulpinilor rezistente la carbapeneme reprezintă o preocupare relativ recentă, motiv pentru care am demarat acest studiu.

MATERIAL ŞI METODE

Lotul de studiu a inclus 498 tulpini de *E.coli* şi *K.pneumoniae* izolate din uroculturi în anul 2009, la Spitalul Clinic "Dr. C. I. Parhon" Iaşi. Testarea sensibilității la antibiotice am efectuat-o prin antibiograma difuzimetrică conform standardelor CLSI 2009 (3). Tulpinile cu sensibilitate modificată la cefalosporine cu spectru larg au fost testate față de trei carbapeneme: ertapenem (ETP), imipenem (IPM) şi meropenem (MEM). Pentru izolatele cu diametrul zonei de inhibiție ≤ 21 mm față de ETP sau/şi MEM am determinat concentrația minimă inhibitorie (CMI) utilizând sistemul automat Phoenix BDExpert; am efectuat screening-ul pentru β-lactamaze cu spectru extins (BLSE) şi pentru carbapenemaze prin testul dublului disc, respectiv testul Hodge modificat (THM) (3). Activitatea beta-lactamazică a extractului sonicat din cultura tulpinii cu THM pozitiv a fost evaluată calitativ prin hidroliza nitrocefinului.

La tulpinile rezistente la carbapeneme am urmărit detectarea genelor ce codifică beta-lactamaze cu spectru extins (tip CTX-M, SHV, TEM) şi carbapenemaze tip KPC prin trei reacții PCR, într-un termociclor Mastercycler personal (Eppendorf, Germania), conform unor metode descrise anterior (1,4,5). Primerii utilizați, dimensiunea ampliconilor şi temperaturile de atașare sunt prezentate în tabelul I.

TABELUL I

REZULTATE ŞI DISCUȚII

În anul 2009, 552 (88,6%) din uroculturi au fost pozitive cu bacili gram-negativi din familia *Enterobacteriaceae*, *E. coli* şi *K. pneumoniae* reprezentând cei mai frecvenți agenti etiologici (429, respectiv 69 tulpini). Un procent de 21,9% tulpini *E.coli* şi 30,4% tulpini *K. pneumoniae* au prezentat sensibilitate modificată la cefalosporine cu spectru extins; dintre acestea, numai la două tulpini *K. pneumoniae* diametrul zonelor de sensibilitate la ETP a fost redus. Ambele tulpini au fost rezistente la peniciline cu şi fără inhibitori de beta-

lactamază, cefalosporine, monobactam precum și la antibiotice din alte clase (tab. II). Una dintre tulpini, K_A a dovedit rezistență la ETP, MEM și IPM (CMI > 8 µg/ml); cealaltă tulpină, K_B a fost rezistentă la ETP, dar sensibilă la MEM și IPM. *Screening*-ul pentru BLSE a fost negativ în ambele cazuri. Testul Hodge modificat a fost pozitiv pentru K_A și negativ pentru K_B (fig. 1).

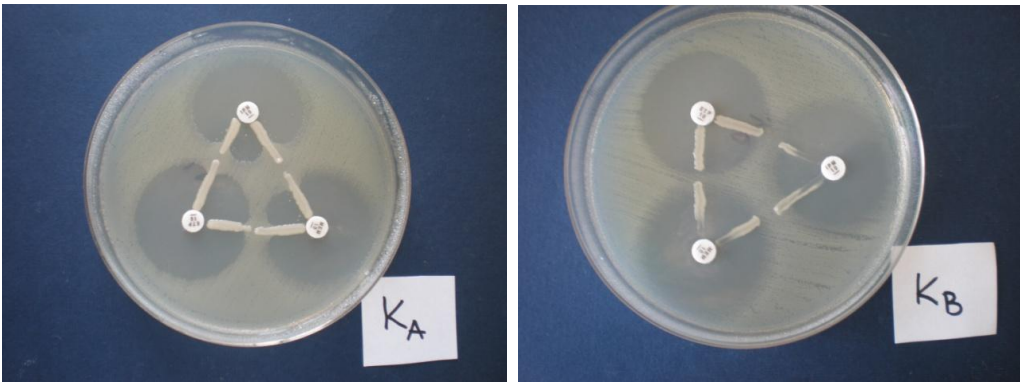

Fig. 1. Testul Hodge modificat: pozitiv pentru tulpina KA (tulpina E.coli ATCC 25922 cultivă spre discul cu carbapenem la locul de intersecție cu tulpina testată – aspect de frunză de trifoi); negativ pentru tulpina KB (conturul zonei de inhibiție circular, nemodificat).

Rezultatele acestor teste fenotipice neau determinat să suspectăm intervenția unor mecanisme diferite de rezistență la carbapeneme: prin producere de carbapanemaze (K_A) sau prin producere de β-lactamaze cu spectru extins în asociere cu pierderea unor porine (K_B). Extractul enzimatic obținut prin sonicarea culturii bacteriene K_A a hidrolizat nitrocefinul, acțiune inhibată de cloxacilină, fapt care sugerează prezența unei cefalosporinaze de tip AmpC (6). Analiza genetică prin PCR cu primeri specifici pentru genele *bla*KPC, *bla*TEM, *bla*CTX-M, *bla*SHV a fost negativă pentru KPC şi TEM; tulpina K_A posedă o genă SHV, iar K_B una CTX-M (tab. III). Lipsa secvențierii face imposibilă precizarea tipului de enzimă SHV (clasic sau BLSE).

TABELUL III
Rezultatele analizei prin PCR

	*bla*CTX-M	*bla*SHV	*bla*TEM	*bla*KPC
Tulpina K_A	-	+	-	-
Tulpina K_B	+	-	-	-

Rezistența *K. pneumoniae* prin producere de carbapenemaze KPC a fost semnalată în urmă cu un deceniu în SUA iar ulterior în alte țări (Canada, Columbia, Brazilia, China, Israel, Marea Britanie, Grecia, Franța, Italia, Polonia, Elveția, Spania) (1, 7, 8, 9). Fenomenul este alarmant întrucât acest tip de enzime inactivează toate antibioticele β-lactamice, se asociază cu rezistență la antibiotice din alte clase (aminoglicozide, fluorochinolone) şi sunt codificate de gene plasate pe elemente mobile, ceea ce face posibil transferul acestui mecanism de rezistență la alți bacili Gram-negativi (*Enterobacteriaceae, Pseudomonas aeruginosa*). Aceste tulpini au de asemenea un potențial ridicat de răspândire pacient-pacient, necesitând măsuri severe de supraveghere epidemiologică. În România acest fenotip nu a fost încă raportat.

În plus, literatura cuprinde multiple semnalări ale diverselor combinații de determinanți de rezistență: alterarea permeabilității membranei externe asociată cu cefalosporinază AmpC (2) sau cu betalactamaze cu spectru extins (CTX-M, SHV-2), însoțite de o creşterea variabilă a CMI la carbapeneme, cel mai constant fiind afectat ertapenem (10, 11). Totodată, s-au înregistrat până la 25% rezultate fals pozitive la testul Hodge modificat, mai ales pentru izolate producătoare de CTX-M sau hiperproducătoare de AmpC (11, 12).

În acest context putem explica rezistența la ertapenem a tulpinii K_B prin asocierea dintre CTX-M şi pierderea unor porine. Tulpina K_A nu s-a dovedit producătoare de carbapenemază KPC, rezistența la cele trei carbapeneme implicând sinteza de beta-lactamaze multiple (AmpC, SHV) însoțită de o scădere a permeabilității membranei externe.

CONCLUZII

Au fost izolate din infecții urinare primele două tulpini *K. pneumoniae* din Nord-Estul României cu sensibilitate modificată la carbapeneme. Mecanismul de rezistență nu apare mediat de carbapenemaze, fenotip relativ recent descris în literatură, care limitează posibilitățile actuale de terapie antibacteriană şi necesită măsuri drastice de supraveghere epidemiologică. Testele fenotipice şi moleculare care ne-au fost accesibile pledează pentru un mecanism dual de rezistență, prin producere de cefalosporinaze asociată cu pier-

derea de porine.

Interpretarea testului Hodge modificat, recomandat de standardul testării sensibilității la antibiotice pentru detectarea fenotipică a carbapenemazelor la *Enterobacteriaceae*, trebuie făcută cu prudență, datorită unor rezultate fals pozitive, mai ales în zonele cu prevalență crescută a tulpinilor producătoare de beta-lactamaze cu spectru extins, cum este țara noastră.

THE VALUE OF 3-DIMENSIONAL MODEL IN MANDIBULAR SEGMENTARY DEFECT RECONSTRUCTION. A CASE REPORT (Abstract) : The use of autogenous bone graft in the reconstruction of mandibular defects following tumor extirpation is a reliable method for further functional rehabilitation. The exact amount of bone needed for harvesting is usually achieved by estimation of the gap and direct measuring. We present the case of a 51-years old patient referred to our clinic for a recurrent mandibular keratocyst. Besides clinical examination, the diagnosis work-up consisted of ortopantomography and computertomography (CT). Based on CT images, a graphic reconstruction of the mandible was realized and a 3D negative template of the scheduled mandibular defect was printed. The tumor was removed by a segmental resection of the mandible, while a fragment of bone tissue similar to the 3D model was harvested from the iliac crest. This bone fragment replaced the mandible defect and was fixed by means of four plates and titanium screws. No postoperative complications occurred. The pathology result confirmed the diagnosis of keratocyst. In conclusion, this method proved to be useful for precise planning of the shape and size of the graft in addition to exact placement of the graft in an acceptable prosthodontically position for future dental implant rehabilitation. **Key words** : 3-DIMENSIONAL MODEL, MANDIBULAR DEFECTS, FREE BONE GRAFT

Reconstrucţia pierderilor de substanţă osoasă segmentare ale mandibulei este o problemă complexă şi mereu actuală în chirurgia reparatorie maxilo-facială. Restaurarea arhitecturii mandibulare este esenţială pentru echilibrul şi simetria feţei ca şi pentru o masticaţie, deglutiţie şi fonaţie normală (1).

Întocmirea planului reconstructiv este întotdeauna condiţionată de sediul şi întinderea pierderii de substanţă, de natura acestor pierderi, de starea părţilor moi de vecinătate şi a dentiţiei precum şi de vârsta şi starea generală a bolnavului.

De asemenea, un rol deosebit de important în reconstrucţia definitivă a defectelor osoase în continuitate ale mandibulei o are materialul reconstructiv alături de reconstrucţia tridimensională cât mai exactă a segmentului osos îndepărtat (2). Studiile experimentale şi clinice au demonstrat superioritatea incontestabilă a transplantelor autogene proaspete comparativ cu oricare alt material de

reconstrucţie (3,4,5,6). Pentru aprecierea cât mai exactă a dimensiunilor pierderii de substanţă de un real folos sunt modelele reproductibile tridimensionale confecţionate pe baza tomografiei computerizate (CT) (7).

PREZENTAREA CAZULUI

Pacienta G.R., în vârstă de 51 ani, s-a internat în martie 2010 pentru un keratochist recidivat de ram orizontal şi unghi drept al mandibulei. Prima intervenţie chirurgicală a fost efectuată în urmă cu 5 ani şi a constat în chistectomie cu meşare. La această ultimă internare pacienta prezenta o discretă deformare a regiunii genio-maseterine drepte în 1/3 inferioară, determinată de prezenţa formaţiunii tumorale care evolua din grosimea osului erodând şi desfiinţând în totalitate ambele corticale osoase (fig. 1). Mucoasa acoperitoare era integră dar aderentă de leziune, iar la palparea bimanuală se percepea fluctuenţă (fig. 2).

Ortopantomografia a evidenţiat o radiotransparenţă multiloculară la nivelul ramului orizontal drept mandibular în 1/3 distală : 4.6 (spaţiu edentat) – unghi drept (fig. 3).

Examenul CT a relevat prezenţa unei leziuni expansive radiotransparente, septate, cu contur policiclic, având aceeaşi localizare ca şi pe ortopantomografie, care întrerupea ambele corticale osoase (fig. 4, 5).

Pe baza examenului CT s-a efectuat reconstrucţia grafică a mandibulei afectate (fig. 6a şi 6b).

În scopul recoltării unui fragment osos cu aceeaşi dimensiune ca a osului rezecat, necesar reconstrucţiei osoase imediate, am confecţionat preoperator un model tridimensional (3D) pe baza examenului CT. În acest sens datele obţinute au fost procesate şi transformate în format 3D, ulterior fiind convertite în format stereolitografic (STL) utilizându-se 3 tipuri de software (8). După această operaţiune dificilă, cu ajutorul unei imprimante 3D s-a realizat modelul anatomic ce include şi leziunea (fig. 7).

Fişierul STL de la modelul anterior a fost introdus într-un alt program de software şi s-a creat astfel un model nou folosindu-se o funcţie "imagine în oglindă" luându-se ca

reper ramul orizontal controlateral (sănătos) al mandibulei. Acest model a fost ulterior creat prin imprimare 3D şi sterilizat pentru a fi utilizat în sala de operaţie (fig. 8).

Intervenţia chirurgicală a constat în extirparea tumorii prin rezecţie segmentară de mandibulă 45-unghi drept, cu abord cutanat (fig. 9). Plastia pierderii de substanţă s-a realizat utilizând modelul tridimensional "ideal". Acesta a fost marcat în dreptul liniilor de osteotomie (fig. 10) şi după radierea dinţilor (fig. 11) a fost secţionat izolându-se astfel un fragment identic cu pierderea de substanţă osoasă (fig. 12). Apoi s-a recoltat din creasta iliacă dreaptă un fragment similar cu cel al modelului tridimensional şi s-a

Fig. 13. Fixarea transplantului în sediul receptor

Fig. 14. Aspect postoperator

fixat în locul pierderii de substanţă mandibulară cu ajutorul a 4 plăcuţe şi şuruburi din titan (fig. 13).

Evoluţia postoperatorie a fost favorabilă.

La 10 luni de la intervenţia chirurgicală nu s-a înregistrat nici o complicaţie (fig. 14).

Diagnosticul histopatologic al piesei de rezecţie a fost de keratochist.

DISCUŢII

Pierderile de substanţă osoasă segmentare ale mandibulei au ca etiologie traumatismele, infecţiile, tumorile şi radionecroza (9). Cel mai frecvent, defectele mandibulare sunt rezultatul extirpării chirurgicale a tumorilor.

În funcţie de localizare, Peri şi col. au clasificat defectele osoase în continuitate ale mandibulei astfel :

- tip I segment simfizar ;
- tip II segment lateral ;
- tip III segment fronto-latero-terminal ;
- tip IV segment condilian + apofiza coronoidă (10).

Cazul prezentat se încadrează în tipul II al clasificării.

Defectele osoase segmentare mandibulare generează prejudicii clinice, morfologice şi funcţionale în strânsă dependenţă cu mărimea defectului şi localizarea sa. Astfel necesitatea reconstrucţiei ramului orizontal mandibular rezidă din următoarele caracteristici :

- constituie un element esenţial al pârghiei mandibulare suportând cele mai mari forţe masticatorii ;
- conţine nervul alveolar inferior responsabil de inervaţia osului mandibular, a dinţilor şi a buzei inferioare ;
- reprezintă în zona distală locul de inserţie a celor mai importanţi muşchi ridicători ai mandibulei (11).

Obligativitatea evaluării cât mai fidele a dimensiunilor pierderilor de substanţă osoasă a determinat crearea modelelor tridimensionale pornind de la examenul CT. Acest lucru a fost menţionat pentru prima dată în 1980 de Alberti (12), iar construcţia primului model cranio-facial a fost raportată în 1987 de către Brix şi Lambrecht (13). Până la realizarea şi utilizarea în practică a acestor modele tridimensionale, aprecierea dimensiunilor pierderilor de substanţă segmentare mandibulare s-a efectuat şi încă se mai efectuează pe baza piesei rezecate şi a plăcii martor de conturare (piesă componentă a truselor de reconstrucţie).

În ceea ce priveşte refacerea continuităţii mandibulare, în prezent există metode chirurgicale variate, fiecare având indicaţiile, limitele şi complicaţiile proprii. Studiile experimentale şi clinice au demonstrat valoarea de necontestat a grefelor de os autolog, acestea reprezentând "standardul de aur" în reconstrucţiile pierderilor osoase în continuitate ale mandibulei (14,15). Dacă dimensiunea pierderii osoase este mai mică de 5 cm se poate utiliza grefa de os autolog nevascularizat (11,16,17). În acest sens, o sursă importantă de os cortico-spongios autogen proaspăt o reprezintă creasta iliacă care poate livra orice formă şi mărime de transplant în cantitatea dorită (18). Pentru a se asigura succesul intervenţiei chirurgicale un rol deosebit de important îl are pregătirea patului de transplantare, modul de recoltare şi modelare a grefonului, fixarea acestuia în *situs*-ul receptor precum şi îngrijirea postoperatorie. Dezavantajele majore ale acestui tip de transplant osos decurg din lipsa aportului vascular propriu cu riscuri legate de resorbţia osoasă sau de apariţia mai frecventă a complicaţiilor infecţioase ce pot conduce la rejetul grefei, comparativ cu grefa osoasă vascularizată.

În cazul prezentat, cantitatea necesară de os s-a recoltat în funcţie de modelul tridimensional confecţionat preoperator. Acest lucru a permis recoltarea unui fragment osos iliac de dimensiuni ideale şi a favorizat scurtarea duratei intervenţiei chirurgicale. În plus reconstrucţia osoasă va permite protezarea ulterioară a zonei edentate, restabilind funcţiile aparatului dento-maxilar.

CONCLUZII

Reconstrucţia imediată a pierderilor de substanţă segmentare ale mandibulei mai mici de 5 cm, utilizând grefele nevascularizate din osul iliac, reprezintă soluţia ideală. Mo-

delul tridimensional permite o planificare precisă şi mai uşoară a plastiei osoase cât şi o recoltare a osului mult mai exactă prin folosirea tiparului negativ a spaţiului ce urmează a fi reconstruit. Deşi laborioasă şi costisitoare, beneficiile aduse de folosirea modelului îl recomandă ca un element valoros şi deosebit de util în protocolul reconstructiv.

IN VITRO EVALUATION OF KETOPROFEN CONTROLLED RELEASE FROM VARIOUS FORMULATIONS

Ana-Maria Oprea, Raluca Petronela Dumitriu, Cătălina Cheaburu, Cornelia Vasile
"P. Poni" Institute of Macromolecular Chemistry Iaşi
Physical Chemistry of Polymers Department

IN VITRO EVALUATION OF KETOPROFEN CONTROLLED RELEASE FROM VARIOUS FORMULATIONS (Abstract): The aim of this study is to investigate the potential utility of some hydrogels, based on chitosan, chitosan modified with phthalic anhydride and 75/25 poly(N-isopropyl acrylamide)/alginate, for preparing drug release systems containing ketoprofen, as model drug. **Material and method**: The *in vitro* release profiles and swelling studies were done in ethanol medium, where the studied drug presents high solubility, at 25^0C (room temperature). The ketoprofen release was observed by monitoring the absorbance at λ_{max} = 254 nm as a function of time. **Results**: The experimental results indicated that the smallest amount of drug was released from chitosan matrices, appreciatively 31%. **Conclusions**: The composition of hydrogels had an important effect on ketoprofen release. **Key words**: ALGINATE, CHITOSAN, SWELLING, CONTROLLED RELEASE, KETOPROFEN

Among the temperature-sensitive hydrogels reported to date, poly (N-isopropyl acrylamide) (PNIPAAm) and its copolymers have been widely used for cell separation as well as for pharmaceutical and tissue engineering applications because of their unique thermo-responsive properties (1,2, 3). PNIPAAm undergoes a reversible temperature-sensitive coil-to-globule transition in aqueous solutions at approximately 32^0C (its lower critical solution temperature, LCST), which lies between room temperature and physiological temperature (37^0C). The LCST of PNIPAAm can be increased by copolymerization with hydrophilic monomers or decreased by using hydrophobic monomers (4,5,6).

Alginate, a polysaccharide extracted from brown algae has been used as a hydrophilic component of hydrogels for many biomedical applications. The ability of alginate sodium salt to pharmaceutical industry, being applied as a carrier (hydrophilic matrix) for controlled release of oral dosage forms. Matrices incorporating alginate salts or a combination of alginate with other polymers have been employed to successfully prolong release of many drugs (7,8).

Since chitosan itself is non-toxic (9), biodegradable (10) and biocompatible (11), several biological applications have been reported for chitosan, including chelation processes (12), a cholesterol trap (13) and a drug carrier (14,15). Recently, there has been a growing interest in chemical modification of chitosan to improve its solubility and widen its applications (16,17). The chemical modification is a powerful tool to control the interaction of the polymer with drugs, to enhance the drug loading efficiency as well as tailor the drug release period. Chemically modified chitosans have great utility in controlled release and targeting studies of almost all class of bioactive molecules.

Chitosan has been modified by ionic crosslinking (e.g. with tripolyphosphate, TPP) to prepare intelligent drug delivery systems

(18), and by carboxymethylation for repair and regeneration of bone tissues (19) or use as antioxidant agent (20).

The aim of the present investigation to compare the kinetics of swelling and ketoprofen release from different matrices as N-isopropyl acrylamide (NIP)/alginate (Alg) hydrogel (75/25), chitosan (C) and chitosan modified with phthalic anhydride (CF) matrices.

EXPERIMENTAL

Materials

The monomer N-isopropyl acrylamide (Aldrich) 97% (NIPAAm), the polysaccharide alginic acid extracted from brown algae (Fluka), M_w = 48 000 - 186 000 with reduced viscosity at 25^0C of 2.41 mL·g^{-1}, c = 0.2 g/dL (Alg) and the crosslinking agent N,N'-methylene bis-acrylamide (Fluka) were all used as received.

Chitosan – (Aldrich) with weight average molecular weight M_w = 400 000 and acetylating degree of 68% was used.

Phthalic anhydride-modified chitosan was synthesized as follows: the N- substituted chitosan derivative was obtained by treating chitosan with phthalic anhydride, an Aldrich product, in dimethylsulfoxide (DMSO) under nitrogen flow and mixing for 6 hours at 80°C according to Hirano's method (21). The obtained modified chitosan was further purified by reprecipitation in ice-distilled water and sodium carbonate (Na_2CO_3); then the precipitate was collected, centrifuged and washed with ethyl ether and then dyalized against acetone for 3 days in order to remove the traces of solvent. The structure of obtained product was confirmed by of FT-IR and H-NMR spectra (22).

Ketoprofen is a classical nonsteroidal anti-inflammatory (first generation), analgesic and antipyretic drug efficient in the treatment of the rheumatoid arthritis and osteoarthritis, spondylitis, as well as soft tissue injuries and also to reduce fever. It is

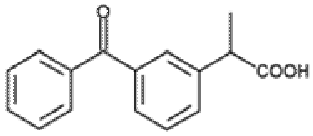

Fig. 1. Structure of ketoprofen (23)

a water insoluble substance but it dissolves in solvents like ethanol, methylene chloride, dimethylsulphoxide (DMSO) and dimethylformamide (DMF). The structure of ketoprofen is presented in fig. 1.

METHODS

Swelling kinetics

The kinetics of the swelling was carried out by weight measurements performed at room temperature in ethanol. The equilibrium swelling degree was calculated according to the Eq. (1).

$$Q_{max}\,(\%) = (W_t - W_d)/W_d \bullet 100 \qquad (1)$$

where W_t is the weight of the swell samples at time t and W_d is the dry weight of the sample.

To determine the kinetics of solvent diffusion into the matrices (swelling) the following equation was used (24):

$$F_t = \frac{W_t}{W_{eq}} = k_{sw} t^{n_{sw}} \qquad (2)$$

where W_t and W_{eq} represent the amount of ethanol solution, absorbed by the matrices at time t and at equilibrium, respectively, k_{sw} is the swelling constant characteristic of the system and n_{sw} is the power law diffusion exponent which takes into account the type of solvent transport. Eq. (2) applies to initial states of swelling (swelling degree less than 60%) and linearity is observed when log F_t as a function of log t is represented.

Drug loading and *in vitro* release studies

The drug loading of the hydrogel matrices was carried out by mixing ketoprofen with dried hydrogel in powder form. During the drug release study, at predetermined time intervals, 1 mL sample was withdrawn

from the release medium and concentration of ketoprofen at 254 nm in the release medium were determined using a UV-VIS spectrophotometer HP 8450A.

The concentrations of the drugs were calculated based on calibration curves determined for drug at specific maximum absorption wavelengths.

A simple, semi-empirical equation using Korsmeyer and Peppas model was used to kinetically analyze the data regarding the drug release from studied matrices system which is applied at the initial stages (approximately 60 % fractional release) (25, 26,27,28,29,30,31) :

$$M_t / M_\infty = k_r t^{n_r} \quad (3)$$

where $M_t/M_á$ represents the fraction of the drug released at time t, M_t and M_8 are the absolute cumulative amount of drug released at time t and at infinite time (in this case maximum release amount in the experimental conditions used, at the plateau of the release curves), respectively, k_r is a constant incorporating characteristics of the macromolecular matrix and the drug n_r is the diffusion exponent, which is indicative of the release mechanism. In the equation above a value of $n_r = 0.5$ indicates a Fickian diffusion mechanism of the drug from matrix, while a value $0.5 < n_r < 1$ indicates an anomalous or non-Fickian behaviour. When $n_r = 1$ a case II transport mechanism is involved while $n_r > 1$ indicates a special case II transport mechanism (32,33,34,35).

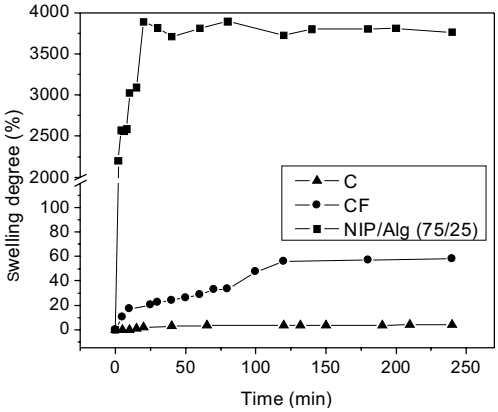

Fig. 2. Swelling profiles of studied hydrogels in ethanol medium, at 25 ^{0}C

The corresponding drug-release profiles were represented through plots of the cumulative percentage of drug release versus time.

FT-IR spectroscopy

The hydrogels loaded with ketoprofen were analyzed by FT-IR spectroscopy, using the KBr pellet technique. The spectra were scanned on a Bruker VERTEX 70 (USA) device, over a 4000-500 cm^{-1} range, at a resolution of 4 cm^{-1}.

RESULTS AND DISCUSSIONS

Swelling kinetic studies

The swelling behaviour of the tested matrices in ethanol medium at 25^{0}C is shown in fig. 2.

To determine the swelling behavior, the chitosan-based matrices were tested in saturated ethanol vapors atmosphere, at 25^{0}C. The swelling of chitosan in ethanol is very low of only 4%. It is evident that the character of swelling curves for both chitosan matrices is different, because of modifying process with phthalic anhydride, the swelling ratio in this case increased being of 58%.

For 75/25 NIP/Alg hydrogels, the swelling studies were done by immersing the samples in ethanol solution at 25^{0}C, reaching a stable equilibrium after 30 minutes with a swelling degree of 3800 %.

In tab. I, the kinetic parameters of swelling for studied hydrogel are given.

The values obtained for swelling parameter (n_{sw}) in ethanol medium at 25^{0}C varies in range between 0.01-0.15 indicating an anomalous mechanism of swelling.

In vitro release studies

In case of chitosan-based matrices, the modification process with phthalic anhydride, determines a difference between amounts of drug released, the highest percent, about 43%, being obtained for CF-

TABLE I
Kinetic parameters of swelling for studied hydrogels

Hydrogels	n_{sw}	k_{sw} (min^{-n})
C	0.01	0.94
CF	0.05	0.65
75/25 NIP/Alg	0.15	0.53

-based matrices and the lowest for chitosan matrix. Release profiles are similar with the swelling ones. To explain this behaviour FT-IR spectroscopy is used. Appreciatively 96% amount of drug released characterizes the 75/25 NIP/Alg hydrogels.

Infrared spectroscopy was used to study the interactions between the drug and the polymers. The spectra of the studied systems are given in fig. 4.

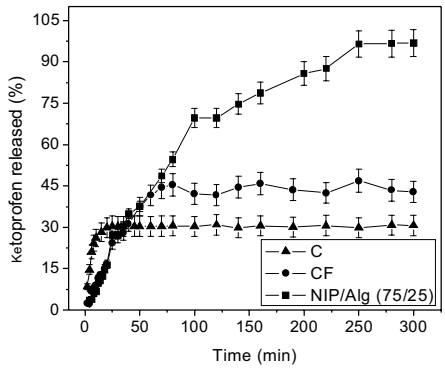

Fig. 3. The release profiles of ketoprofen in ethanol from studied hydrogels, at 25^{0}C

Ketoprofen has a carboxylic acid group, which can interact with the functional groups of the polymers. For ketoprofen, the cha-

TABLE II
The kinetic parameters of ketoprofen released from studied matrices

Hydrogels	Korsmeyer-Peppas equation			First order kinetic model	
	n_r	R	$k_r 10^3$ (min^{-n})	$k_r 10^3$ (min^{-1})	R
C	0.72	0.99	55.25	33.04	0.98
CF	0.83	0.99	14.14	8.16	0.99
75/25 NIP/Alg	1.18	0.99	4.43	7.52	0.98

racteristic bands appeared at 2876 cm^{-1} due to CH stretching of CH3 group masked by symmetric OH, 1697 cm^{-1} due to the C=O stretching vibration of the carboxylic group, a band observed at 1655 cm^{-1} represented by the carbonyl C==O stretching vibrations, and a wide band between 811 cm^{-1}-642 cm^{-1}, characteristic to C-H deformation of aromatic ring (fig. 4a).

In case of NIP/Alg (75/25) ketoprofen loaded hydrogels, the IR spectra showed characteristic peaks of ketoprofen at 2974 cm^{-1}-2876 cm^{-1}, 2169 cm^{-1}-2125 cm^{-1}, 1650 cm^{-1} regions and 839 cm^{-1}-1094 cm^{-1} band (fig. 4b).

For chitosan-phthalic anhydride ketoprofen loaded matrices, the IR spectra showed characteristic peaks of ketoprofen at 2978 cm^{-1}-2877 cm^{-1} band, 1384 cm^{-1}, 1651 cm^{-1}, and the region 834 cm^{-1}-615 cm^{-1}, respectively (fig. 4c).

The spectra of ketoprofen loaded hydrogels prepared with chitosan showed that the peaks at 1697 cm^{-1} and 1655 cm^{-1} were found at 1652 cm^{-1} and 1646 cm^{-1} respectively and the band 811 cm^{-1}- 642 cm^{-1} is replaced by 758 cm^{-1}-502 cm^{-1} bands, respectively (fig. 4d) which indicate major modifications in the structure after loading.

These bands correspond to amide groups indicating formation of a new compounds and possible drug-matrix interactions through covalent bonding and/or hydrogen bonding. This explains the slower release rate and smaller release amount of ketoprofen from the chitosan matrix.

Kinetic mechanism

The kinetic parameters for ketoprofen release in ethanol solution from tested hydrogels are presented in table II.

The values of the diffusion exponent (n_r) obtained for ketoprofen release from tested matrices indicates an anomalous transport mechanism for chitosan and chitosan modified with phthalic anhydride hydrogels, namely 0.72 and 0.83, respectively, which appeared by coupling Fickian diffusion with the relaxation of the hydrogel network. For 75/25 NIP/Alg hydrogel the n_r value is 1.18 sugesting a case II transport mechanism.

CONCLUSIONS

Potential applications of chitosan-based matrices and 75/25 NIP/Alg hydrogels in controlled drug delivery were tested. The composition of hydrogels had an important effect on ketoprofen release.

The swelling exponent values $n_{sw} < 0.5$ indicated a non-Fickian character of ethanol diffusion into the hydrogels.

The values of the diffusion exponent (n_r) obtained for ketoprofen release from chitosan-based matrices indicates an anomalous transport mechanism and a case II transport mechanism for 75/25 NIP/Alg.

NOUTĂŢI

TERAPIE CU ^{131}I ÎN TUMORI MALIGNE NON-TIROIDIENE ?

Sistemul de transport Na/I (Na/I symporter, NIS) este o proteină existentă în mod normal în membrana celulelor tiroidiene, care mediază influxul de iod, atât stabil, utilizat, ulterior, fiziologic în sinteza hormonilor tiroidieni, cât şi radioactiv (^{131}I, ^{123}I, ^{124}I), permiţând vizualizarea scintigrafică tiroidiană şi mediind radioiodoterapia cancerului tiroidian. Captarea scintigrafică tiroidiană de $^{99m}TcO_4^-$ este, de asemenea, mediată de proteina NIS. Studii experimentale recente aduc în discuţie posibilitatea utilizării NIS pentru imagistica neinvazivă a expresiei genice şi, posibil, radioiodoterapia unor tumori maligne non-tiroidiene cărora li s-a indus genetic expresia membranară a acestei proteine (Baril P, Martin-Duque P, Vassaux G. Visualization of gene expression in the live subject using the Na/I symporter as a reporter gene : applications in biotherapy. *Br J Pharmacol* 2010 ; 159 (4) : 761-771) .

CLINICAL AND MICROBIOLOGICAL STUDY REGARDING SURFACE ANTIBACTERIAL PROPERTIES OF BIOACTIVE DENTAL MATERIALS (Abstract): In the new era of dentistry the coronal restoration materials must possess „bio-active" features represented by fluor ions release, chemical adhesion and antibacterial agents. **Aim**: Our study aims to determine the surface antibacterial properties of glassionomer cements and compomers. **Materials and method**: The study group included 64 patients with high cariogenic risk with 80 teeth with acute and chronic dental caries affecting proximal and occlusal dental surfaces. The teeth with cariogenic lesions were restored with zinc-oxide-eugenol (n=20), glassionomer cement GC Fuji Triage (n=20), glassionomer cement modified with resins Fuji II LC (n=20), compomer Dyract (n=20). DENTOCULT SM test (Orion Diagnostica, Finland) was used for bacterial analyses. The samples from bacterial biofilm were collected from the restorated dental surfaces (study group) and intact enamel surfaces (control group). The recorded data were processed using non-parametrical statistical tests. **Results**: The lowest mean value of bacterial indices was recorded for glassionomer cement Fuji Triage (0.4), and Fuji IILC (1.2), material with highest surface antibacterial properties. The highest value (1.5) was recorded for compomer Dyract. The Kruskal-Wallis test proves the significant statistical differences between the three bioactive materials. **Conclusion**: The materials with bioactive features have the ability to inhibate the growth of *Streptococcus mutans* in bacterial biofilm to the surfaces of coronal restoration. **Key words**: BIOACTIVE MATERIALS, SURFACE ANTIBACTERIAL PROPERTIES, DENTOCULT SM, GLASSIONOMER CEMENTS, COMPOMERS

ESTHETIC REHABILITATION THROUGH CAD/CAM TECHNOLOGY - CASE REPORT

ESTHETIC REHABILITATION THROUGH CAD/CAM TECHNOLOGY-CASE REPORT (Abstract): With the progress of dental materials and techniques, CAD/CAM system currently allows the manufacture of high precision prosthetic restorations. Zirconia is an ideal base for porcelain because the bonding process between the zirconia and the porcelain is stronger than it is with porcelain and metal. This means that the porcelain is less likely to fracture away from a zirconia base. Zirconia can also be colored to match teeth and it is translucent, mimicking the natural look of teeth far better than any crown with a metal base could. The aim of this article is to describe a case of oral rehabilitation, involving CAD/ CAM technology for full dental crowns, using zirconia as framework. **Keywords:** DENTAL CROWNS, ZIRCONIA FRAMEWORK, CAD/CAM TECHNOLOGY.

The popularity of metal-ceramic restorations is largely due to its qualities- high mechanical resistance and reasonable esthetics. Among others, such restorations have some color disadvantages, the metal infrastructure being difficult to be completely masked by the opaque layer (1, 2). Since the esthetic expectations in dentistry are growing, research in the field of materials for all-ceramic restoration and dental implants was intensified (3). In the last years, zirconia based ceramics became an optimal alternative in the prosthetic rehabilitation due its mechanical and optical properties (4, 5, 6). With the progress of dental materials and techniques, Computer-Aided Design/Computer-Aided Manufacturing (CAD/CAM) system currently allows the manufacture on fixed prosthesis, implants (7,8) and became a reality in dental practice. Zirconia framework is esthetically and biologically better accepted than the metal framework, and is very well tolerated by patients. It is a fact that systems based on zirconia present beyond the esthetic factors, high strength and radio-opacity, plaque accumulation reduction and low thermal conductivity (9, 10). The aim of this article is to describe a case of oral rehabilitation, involving CAD/CAM technology for dental full crowns, using zirconia as framework material.

CASE REPORT

A 38-year-old female patient came to the dental clinic with esthetic problems, determined by an inappropriate aspect of the metal-ceramic crown on the tooth 2.1. The prosthetic device was poorly cervical fitted and had an improper color appearance. After

clinical and Rx examination, we decided to replace the restoration with a metal-free full crown based on a zirconia framework. The old crown was removed and the patient was provisionally protected with a preformed acrylic temporary crown. The impression was registered, using the wash-technique, then, the temporary crown was cemented with Temp Bond. Based on the impression, the dental technician created two dental casts: one for scanning and the other for the final adaptation and tray-in of the prosthetic device. For the zirconia infrastructure realization, the Schütz Dental Tizian CAD-CAM system was used. The first step consists in a highly accuracy optical impression of the model, by scanning the plaster model inside the Tizian Smart-Scan chamber (fig. 1).

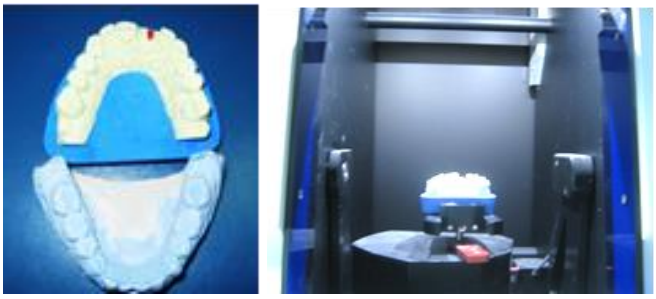

Fig. 1. Scanning the model in the Tizian Smart-Scan chamber

The results of the scanning process were viewed on the monitor, in profile and in section, to check the accuracy of each detail. After scanning, the information was stored in the database, in order to create a virtual model (fig. 2). For designing the framework through software, the opposite arch and occlusal relationship should also be scanned, allowing the mounting of the 3D models in the program.

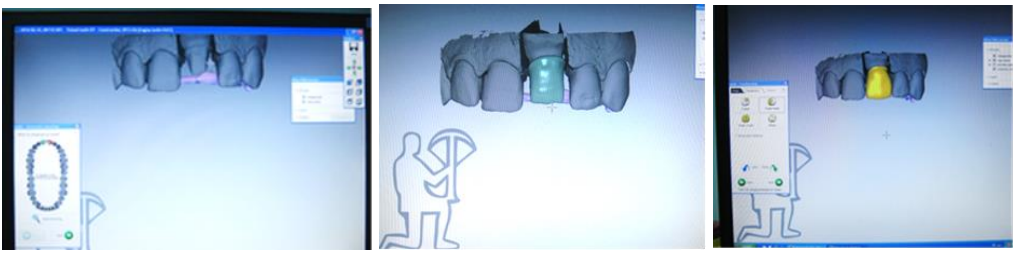

Fig. 2 Building the virtual prosthetic restoration

The design of prosthetic piece was obtained virtually (the CAD phase) and sent to the milling machine, in order to manufacture the framework by milling the ceramic blocks (CAM phase). The IPS e.Max system used was zirconia infiltrated with lithium-disilicate glass ceramic. The framework includes esthetics, mechanical performance, economic feasibility and utilization. The zirconia framework must be veneered with another ceramic system, the Tizian ceramic (Schutz Dental) being used because it offers a very dense surface, the hardness values are very similar to those of natural enamel, is very gentle on the antagonists and is color-stable during time (fig. 3).

Fig. 3 Milling the zirconia framework

The external polished surfaces were first cleaned in deionized water, and subsequently by ultrasound in butanone and ethanol. The final try-in of the restauration was realized on the model and in the oral cavity, as well (fig. 4). The final setting of the crown was done with self-curing resin cement for zirconia, RelyX™ Unicem (3M Espe Dental).

Fig. 4 The dental crown control

DISCUSSION

The current popularity of metal-ceramic restorations declined as a result of certain disadvantages: structural weakness, risk of errors due to the complexity of the fabrication procedure, esthetic inconveniences. The emergence of new materials and technologies open the way to achieving dental restorations with longevity over time and well accepted by patients. All-ceramic crowns based on zirconia frameworks have advantages of their mechanical and optical properties; in addition, zirconia crowns are manufactured using CAD/CAM technology, 10, 11), which allows shortening of working time, after the elimination of many laboratory steps. Zirconia is an ideal base for porcelain because the bonding process between the zirconia and the porcelain is stronger than it is with porcelain and metal. This means that the porcelain is less likely to fracture away from a zirconia base. Zirconia can also be colored to match teeth and it is translucent, mimicking the natural look of teeth far better than any crown with a metal base could. The metal free crown is long lasting, easier to wear and more durable than other crowns (12, 13).

CONCLUSIONS

Our clinical experience demonstrates that metal ceramic prosthesis is not always very well accepted by the patients because of some color disadvantages. Zirconia is a modern possibility to replace the metal frame in porcelain crowns and bridges and fulfill the purpose of restoring function and simultaneously ensure fundamental esthetics requirements on oral rehabilitation.

The CAD-CAM technology allowed our

prosthesis realization in a very short time, as result of eliminating a lot of laboratory steps, because zirconium dental restorations are made by cutting a solid block of zirconia with very high accuracy. The clinical exam demonstrated very good esthetic and functional results and after six months there are no biological or mechanical complications. Because of the absence of internal metal structure, light passes through similar to the natural tooth and it is reflected in the same way, which is very important, especially for frontal restorations. Being a biocompatible material, it is very well accepted by the body and there is no risk of allergic reaction and because is thermo-insulating, the temperature variations are not transmitted to the dental pulp, thereby decreasing the risk of a possible future pulp inflammation.

So, we concluded that zirconia crown technology is an exceptional therapeutic solution, aesthetical and mechanically speaking. Also, in the future, zirconium will be a convenient solution for the dental labs because the technology is fast and accurate.

EVALUATION OF THE ANTIOXIDANT ACTIVITY OF SOME IMINES DERIVATIVES OF L-ARGININE (Abstract): L-Arginine is an α-amino acid which plays important roles in different diseases or processes, such as Alzheimer disease, inflammatory process, healing and tissue regeneration and it also could be useful as an anti-atherosclerotic agent. **Aim**: Considering the large amount of studies on the beneficial effects of different antioxidants, this paper is focused on the evaluation of the antioxidant potential of some imine derivatives, synthesized by the authors and described in a previous article. **Material and Methods**: The evaluation of the antioxidant power was performed using phosphomolydenum-reducing antioxidant power (PRAP) and ferric reducing antioxidant power (FRAP) assays, tests described in the literature and which are used with some minor modifications. **Results**: It was found that most of the imine derivatives are more active than the L-Arginine in the PPAP and FRAP assays. The most active derivative was the compound obtained by condensation of L-arginine with 2,3-dihydroxybenzaldehyde (2k) and 2-nitrobenzaldehyde (2g). **Conclusions**: Following the described protocol, some imine derivatives of L-arginine were evaluated in terms of antioxidant potential using *in vitro* methods. The most favorable influence was obtained by the aromatic substitution with *nitro* and *hydroxyl*, the corresponding derivatives being the most active derivatives compared to L-arginine. **Keywords**: L-ARGININE, IMINE, ANTIOXIDANT ACTIVITY.

L-Arginine is one of the most metabolically versatile amino acids. It is classified as a semi-essential or conditionally essential amino acid, depending on the stage of development and on the individual state of health (1). L-Arginine serves as a precursor for the synthesis of polyamines, proline, glutamate, creatine, agmatine and urea (2). It also serves as a precursor for the synthesis of proteins and is a substrate for different enzymes. For example, the nitric oxide synthase (NOS) converts arginine to nitric oxide (NO) and citrulline. NO is a signal molecule involved in many processes such as: vasodilatation, angiogenesis (3, 4), immune responses, epithelialization and formation of granulation tissue and inhibition of platelet activation/aggregation (5, 6). L-Arginine is also reported to act as an free radical scavenger, because it inhibits the activity of pro-oxidant enzymes, thus acting as an antioxidant, all these effects being mediated by NO

(7, 8). The imine derivatives are cited the in literature for their wide range of biological activities such as: antifungal, antibacterial, antimalarial (9), ant proliferative (10), anti-inflammatory (11), antiviral and antipyretic (12) and antioxidant (13) effects. The increasing interest in imines is due to their easy synthesis and wide applicability, antioxidant effects included.

Based on these considerations, new compounds derived from L-arginine were synthetized (14) and evaluated for their antioxidant properties.

MATERIAL AND METHODS

The organic solvents (*p.a.* quality) and the standard reagents used for the antioxidant tests were purchased from Sigma Aldrich Company and Fluka Company. All solvents and reagents were used without prior purification.

Chemistry

The imine derivative synthesis. The synthesis of the imine derivatives consisted in the condensation of L-Arginine in methanol with various aromatic aldehydes (4-chloro/4-fluoro/4-bromo/2-nitro/3-nitro/4-nitro/2-hydroxy/3-hydroxy/2-methoxy/2,3-dihydroxy/2,4dihydroxy/ 2,4, 6-trihydroxy-benzaldehyde) which led to the corresponding derivatives (2a-m) (Fig. 1).

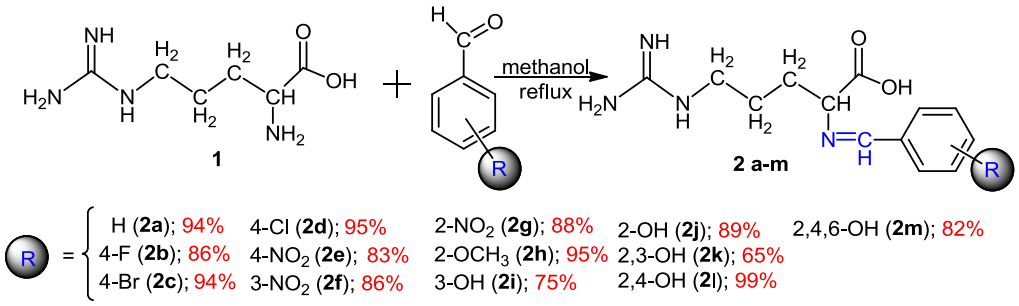

Fig. 1. Synthesis of L-arginine derivatives

The synthesis and spectral characterization of the synthesized compounds were reported in our previous article (14).

Antioxidant assays

Phosphomolydenum-reducing antioxidant power (PRAP) assay. The total antioxidant capacity of the synthesized compounds was evaluated using phosphomolybdenum method (15) with some minor modifications. The method is based on the formation of phosphomolybdenum blue complex by the reduction of Mo^{6+} to Mo^{5+} under the action of electron donating compounds. The maximum absorption of the complex was recorded at 695 nm and the reducing antioxidant effectiveness is correlated with high absorbance values.

To obtain a stock solution with the concentration of 5 mg/mL, the imine derivatives were dissolved in DMSO (dimethyl sulfoxide), and L-arginine in double distilled water. From the stock solution different volumes were taken (10 µL, 20 µL, 40 µL, 60 µL) and then completed to by adding DMSO up to 200 µL. To the mixture 2000 µL of reagent (28 mM phosphate, 4 mM ammonium heptamolybdate,

0.6 M sulfuric acid) was added. After preliminary stirring, the solutions were incubated at 95 ^{0}C for 90 min, cooled in cold water and centrifuged at 4600 rpm for 15 min. The supernatant was separated and the absorbance was read at 695 nm against a blank consisting of 2000 µL reagent and 200 µL DMSO. For each compound the effective concentration 50 (EC_{50}) was calculated by linear regression which is the sample concentration at which 50% of the substrate is reduced. Ascorbic acid was used as a positive control and L-arginine, prepared in a similar manner as the samples, as a reference. All determinations were performed in triplicate and the results were expressed as arithmetic mean ± standard deviation (SD).

Ferric reducing antioxidant power (FRAP) assay. The reducing power of the synthesized compounds was measured by the method described in the literature (16, 17) with some modifications. The method is based on the reduction of ferricyanide to ferrocyanide, which is quantified as Prussian Blue, complex which has a maximum absorption band at 700 nm.

To obtain a stock solution with the concentration of 10 mg/mL, the imine derivatives were dissolved in DMSO (dimethyl sulfoxide), and L-arginine in double distilled water. From the stock solutions serial dilution were made in order to obtain the following concentrations: 5 mg/mL, 2.5 mg/mL and 1.25 mg/mL. To 0.5 mL of sample with the above mentioned concentrations, 0.5 mL of 0.2 M phosphate buffer at pH 6.6 was added. The reaction was then initiated by the addition of 0.5 mL of potassium ferricyanide 1% w/v, after which the samples were incubated at 50°C (oven) for 20 min and the reaction was stopped by the addition of 05. mL of 10% (w/v) trichloroacetic acid. After vigorous shaking the samples were centrifuged at 4500 rpm for 15 min. To 1 mL of the supernatant 1 mL of doubly distilled water and 0.2 mL of 0.1% ferric chloride were added. After 5 min the absorbance was read at 700 nm against a blank (the reaction mixture without the sample).

A high absorbance indicates a high reducing power. For each compound EC_{50} was calculated by linear regression, which is the sample concentration at which 50% of the substrate is reduced. Ascorbic acid was used as a positive control and L-arginine, prepared in a similar manner as the samples, as a reference. All determinations were performed in triplicate and the results were expressed as arithmetic mean ± standard deviation (SD).

RESULTS AND DISCUSSION

Phosphomolydenum-reducing antioxidant power (PRAP) assay. The total antioxidant capacity of the imine derivatives of L-arginine (2a-m) was evaluated at four different concentrations: 0.0272 mg/mL, 0.045 mg/mL, 0.090 mg/mL and 0.135 mg/mL. The absorbance values of the phosphomolydenum complex recorded at 695 nm are plotted in Fig. 2. It is noted that the ability of the tested compounds to reduce Mo^{+6} to Mo^{+5} increases with the concentration. The highest increase in absorbance from the concentration of 0.0272 mg/mL to the concentration of 0.135 mg/mL was recorded for the compounds 2e (R = 4-NO_2 (from 0.023 ± 0.013 to 0.322 ± 0.021), 2g (R = 2-NO_2, from 0.109 ± 0.001 to 0.571 ± 0.002) and 2k (R = 2,3-OH, from 0.333 ± 0.006 to 1.233 ± 0.019), the increase was 4 to10 times. For the tested compounds there are not reference data in the literature.

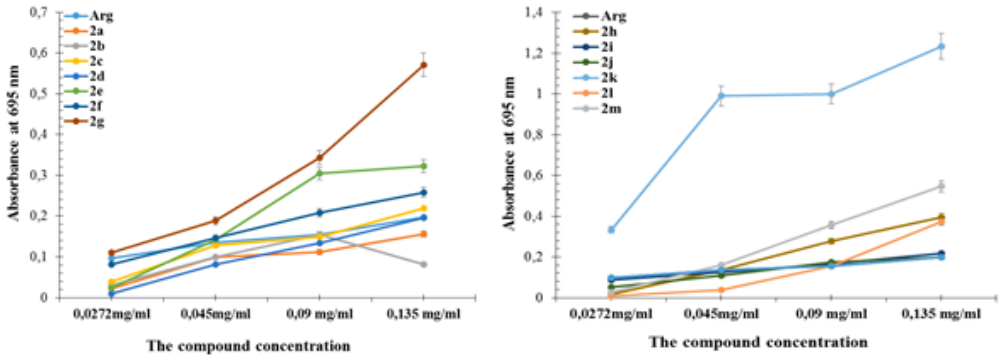

Fig. 2. Absorbance of the imine derivatives (**2a-m**) recorded at 695 nm

The analysis of EC_{50} values (Table I) showed that the most active compounds are 2k (R=2,3-OH, EC_{50}=0.033±0.001) and 2g (R=2-NO_2, EC_{50}=0.087±0.004), for which the total antioxidant capacity is about 38 times and respectively 15 times greater than L-arginine (EC_{50}=1.271±0.042). The compounds 2m (R=2,4,6-OH, EC_{50}=0.196± 0.063), 2f (R=3-NO_2, EC_{50}=0.228±0.008) and 2e (R=4-NO_2, EC_{50}=0.265±0.009) also showed an appreciable total antioxidant activity, being 6.5 times (2m), 5.5 times (2f) and 4.8 times (2e) more active than L-arginine.

TABLE I

EC_{50} values (mg/mL) of the phosphomolybdenum reducing antioxidant power of derivatives 2a-m

* EC_{50} values are the average of three determinations ± standard deviation

Ferric reducing antioxidant power (FRAP) assay. The absorbance values of Prussian Blue complex formed in the presence of imine derivatives at different concentrations (0.189 mg/mL, 0.374 mg/mL, 0.757 mg/mL, 1.515 mg/mL) and recorded at 700 nm are plotted in Fig. 3.

From the analysis of the results it can be noticed that the absorbance of the samples (**2a-m**) and consequently the reducing power increases with the increase in concentration. Except for compound 2a, all tested derivatives are more active than L-arginine, at all concentrations. This highlights the favorable influence of the aromatic ring substitution on the antioxidant activity. The most active compounds were 2e (R = 4-NO_2), 2g (R = 2-NO_2) 2k (R = 2,3-OH) and 2m (R = 2,4,6-OH), for which the absorbance value at 1.515 mg/mL was

approximately 11 times (2e), 14 times (2g), 15 times (2k) and 10 times (2m) higher than that of L-arginine, determined under similar experimental conditions.

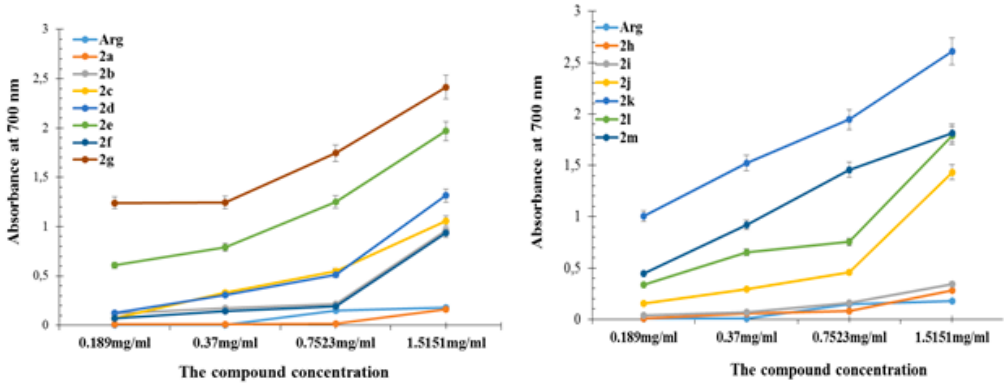

Fig. 3. Absorbance of the imine derivatives (**2a-m**) recorded at 700 nm

The EC_{50}values calculated based on the absorbance values recorded at 700 nm are presented in Table II; low EC_{50}values indicate a high reducing power. The most active compound was found to be compound 2g (R=2-NO_2, EC_{50} = 0.044 ± 0.001) which is about 58 times more active than L-arginine (EC_{50} =2.571±0.024) and 70 times more active than the unsubstituted derivative 2a (EC_{50}=3.08±0.016). Compound 2k (R=2,3-OH, EC_{50}=0.067± 0.001) also had a significant reducing power, being about 38 times more active than L-arginine. Also, compounds 2e (R=4-NO_2, EC_{50}=0.174±0.023) 2m (R=2,4,6-OH, EC_{50}=0.238 ± 0.006) and 2l (R=2,4-OH, EC_{50} =0.372 ± 0.015) were found to be about 15 times, 11 times and 7 times, respectively more active than L-arginine. For the tested compounds there are not reference data in the literature.

TABLE II

Reducing power (EC_{50}, mg/mL) of derivatives 2a-m in comparison with ascorbic acid and the parent compound

Compound	EC_{50} mg/mL	Compound	EC_{50} mg/mL	Compound	EC_{50} mg/mL
L-Arg	1.471 ± 0.024	2e	0.121 ± 0.023	2j	0.974 ± 0.002
2a	0.732 ± 0.016	2f	0.145 ± 0.005	2k	0.112 ± 0.038
2b	0.805 ± 0.031	2g	0.086 ± 0.001	2l	0.091 ± 0.001
2c	0.564 ± 0.023	2h	1.157 ± 0.084	2m	0.859 ± 0.006
2d	1.099 ± 0.009	2i	1.238 ± 0.022	ascorbic acid	0.006 ± 0.001

* EC_{50} values are the average of three determinations ± standard deviation

CONCLUSIONS

In this study the authors assessed the antioxidant potential of 13 imine derivatives of L-arginine using *in vitro* methods: phosphomolydenum-reducing antioxidant power (PRAP) and ferric reducing antioxidant power (FRAP) assays. Most of the studied compounds showed an improved antioxidant

activity compared to L-arginine, fact that proves a favorable influence of structural modulation on the antioxidant effects of L-arginine. For both methods used for the evaluation of the antioxidant potential it was shown that the aromatic substitution with *nitro* and *hydroxyl* has the most favorable impact on the antioxidant activity.

MULTIDISCIPLINARY APPROACH TO PALLIATIVE CARE (Abstract). **Aim:** The purpose is to present an analysis regarding the information, training, need and barriers arising in the provision of palliative care among physicians of different specializations within the Regional Institute of Oncology Iaşi. **Materials and methods:** The data was collected through the questionnaire method, which was filled in by a number of 38 physicians. **Results:** All the staff surveyed was confronted in their professional activity with patients who required palliative care. Only 21.1% of the staff surveyed had training in palliative care certified through courses, internships or volunteering. 39.5% of the physicians surveyed believed that their patients did not benefit from all the palliative care they would have required. All the staff surveyed (with one exception - 2.6%), considered that additional training in palliative care would bring benefits in terms of quality of life of the patients who require palliative care. All the medical staff in oncology/radiology and 95.7% in the other sections considered training in the field of palliative care to be necessary as regards the professional curriculum ($p = 0.827$). **Conclusions:** The respondents stated that better training in the field of palliative care could contribute to enhancing the quality of life of their patients. The physicians surveyed shared the need to follow training courses in palliative care, claiming at the same time that a training module with a duration of approximately 3 months within residency would be beneficial. **Keywords:** PALLIATIVE CARE, TRAINING, DEVELOPMENT, MULTIDISCIPLINARY.

In Romania, palliative care (PC) is currently undergoing a dynamic development and the number of specialized services (mostly bed units) is increasing (1). At the same time, there is a need not only to cover the norms for the staff in the field, but especially to ensure specialized human resources (2) in order to provide quality palliative care services.

According to a sociological study conducted at national level (3, 4), 20.7% of the population has been or is currently confronted with having to provide care for an incurable patient with an advanced or terminal illness, of whom only 1.2% benefited from specialized care services. It is a low percentage which demonstrates the insufficient level of specialized services covered

in terms of the need of palliative care (5).

The education and training of the medical staff in palliative care therefore becomes extremely important. In Romania, the most complex form of specialization in palliative care is currently the achievement of the certification in complementary studies (lasting approximately 2 years), however, there are also shorter courses (both for physicians and nurses), which have a leading role in the initiation in the field or in deepening specific themes.

Palliative care requires a coordinated team approach. No one individual and no one discipline can address the complexity of issues that arise throughout the provision of palliative care (6). Although care is generally provided by a nucleus-team consisting of physician, nurses, psychologist and social workers (7), most often a broader contribution of professionals in the medical field is necessary, in order to provide care for other related specialties as well.

The palliative care in patients with cancer is an important part of the field, at the level of Iaşi county palliative care being provided both in public and private hospital units.

MATERIALS AND METHODS

The purpose of this paper is to present an analysis regarding the information, training, need and barriers arising in the provision of palliative care among physicians of different specializations within the Regional Institute of Oncology Iaşi. The data was collected through the questionnaire method, which was filled in by a number of 38 physicians, and the results were processed by means of *SPSS 16.0* program.

The criteria of inclusion in the study were represented by: the professional degree of physicians regardless of specialty and the informed consent of the participants. The criteria of exclusion from the study were represented by: other professional degrees apart from that of physician and the refusal to process the data after filling in the questionnaire.

RESULTS AND DISCUSSION

The results show that most of the physicians participating in the survey specialized in surgery (31.6%), followed by those from the specialties of medical oncology (28.9%) and hematology (26.3%). A percentage of 10.5% is represented by the physicians specialized in radiotherapy and 2.6% belonging to other specialties (tab. I).

TABLE I
Medical specialties

Specialty	n	%
Medical oncology	11	28.9%
Radiotherapy	4	10.5%
Hematology	10	26.3%
Surgery	12	31.6%
Other (gynecology)	1	2.6%

The distribution on professional titles shows that most of the surveyed physicians are primary care physicians and medical specialists, representing a percentage of 57.8% compared to resident physicians, who account for 42.2% (tab. II).

TABLE II
Professional titles

Professional title	n	%
Primary health care physicians	11	28.9%
Medical specialists	11	28.9%
Resident physicians	16	42.2%

The majority of the surveyed physicians (36.8%) stated a work experience between 1

and 3 years in the provision of care for patients with cancer. A significant percentage (28.9%) declared a seniority of more than 10 years in the provision of care for patients with cancer, and a low percentage (7.9%) less than 1 year experience (tab. III).

TABLE III
Work experience in the provision of care for patients with cancer

Work experience	n	%
< 1 year	3	7.9%
1-3 years	14	36.8%
3-5 years	6	15.8%
5-10 years	4	10.5%
> 10 years	11	28.9%

The results showed that all the staff surveyed was confronted in their professional activity with patients who required palliative care (fig. 1). In the cases studied, the physicians surveyed were most frequently (78.9%) confronted with fewer than 10 cases of palliative care per month, patients who needed hospitalization or ambulatory consultation (fig. 2).

The data analysis revealed that only 21.1% of the staff surveyed had training in palliative care certified through courses, internships or volunteering (fig. 3).

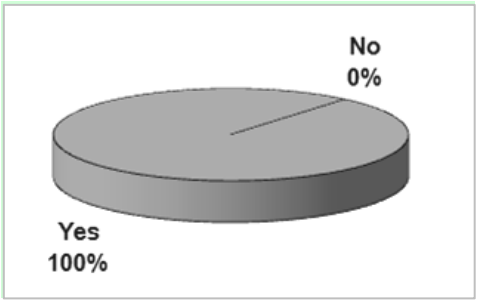

Fig. 1. Confrontation with need of palliative care

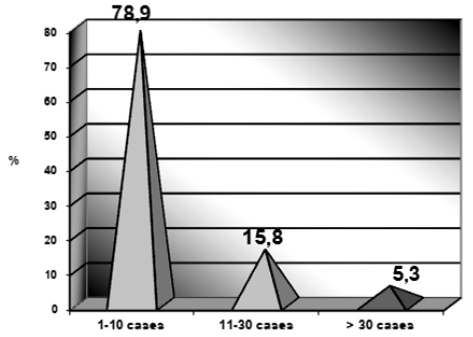

Fig. 2. Number of cases/month who needed palliative care

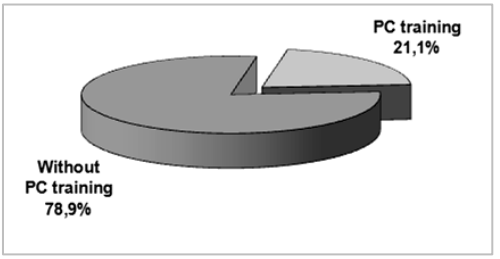

Fig. 3. Training in palliative care

A percentage of 34.2% of the participants considered that the patients whom they treated in their capacity of attending physicians received all the palliative care they required, while 26.3% believed that further knowledge or other material resources would have been necessary in order to provide their patients with full palliative care. 39.5% of the physicians surveyed believed that their patients did not benefit from all the palliative care they would have required, but could not say whether this was due to the absence of knowledge in the field or to some specific material resources (fig. 4).

All the staff surveyed (with one exception - 2.6%), considered that additional training in palliative care would bring benefits in terms of quality of life of the patients who require palliative care (fig. 5).

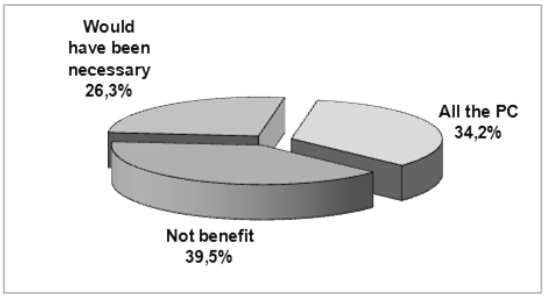

Fig. 4. Benefiting of palliative care

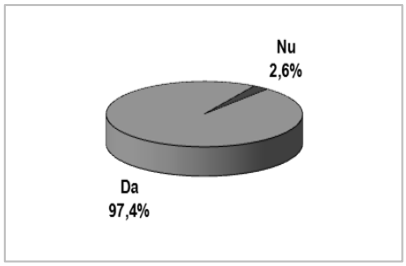

Fig. 5. The necessity of additional training in palliative care

The main barriers to providing palliative care for the patients, according to the respondents, were represented by: insufficient time allotted to the patient, due to the large number of patients that require care/consultation (65.8%); insufficient communication skills in interacting with patients or their family (52.6%); insufficient knowledge regarding pain control (47.4%); lack of guidelines/protocols of palliative care (47.4%); administrative issues (47.4%) (fig. 6).

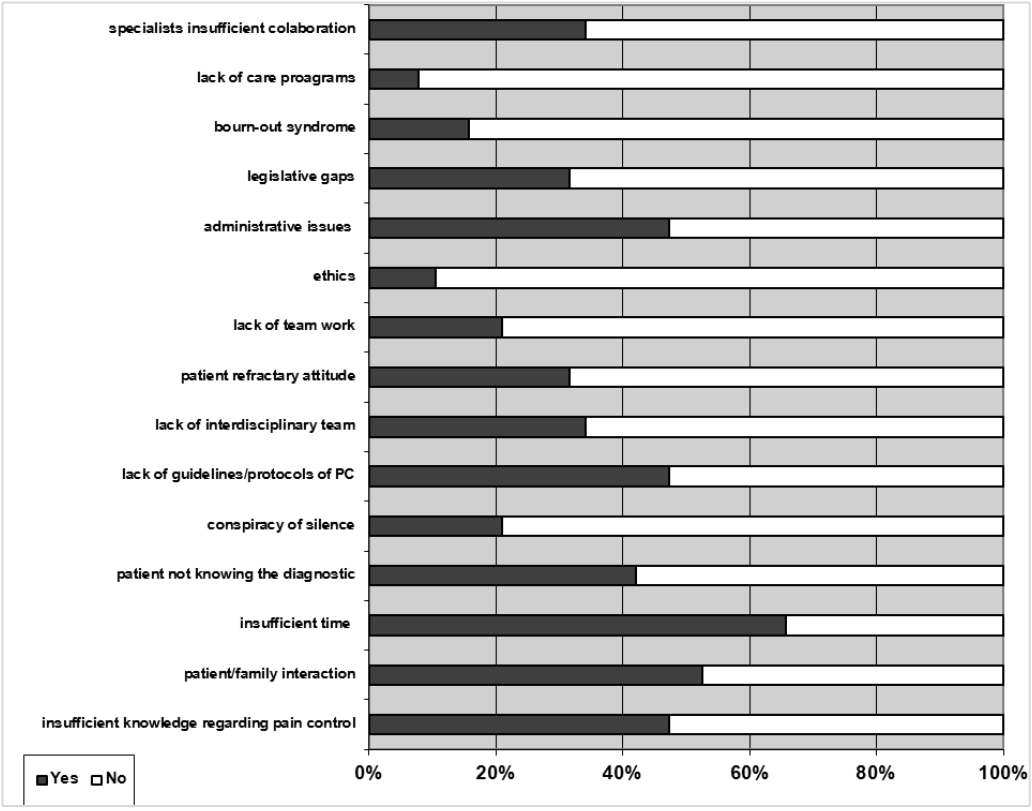

Fig. 6. Barriers to providing palliative care

Due to the fact that the physicians in medical oncology and radiotherapy specialties work with a large number of cancer cases, the 38 physicians surveyed were divided into two groups, as follows: an oncology/radiotherapy group and a group comprising all other specialties. The comparative responses of the people specialized in oncology / radiology *vs.* other specialties revealed that the distribution of respondents according to professional title was uniform (p=0.676), in the oncology / radiology services predominating physicians with seniority under 3 years in cancer patient care (p = 0.041), which is due to the higher number of medical residents and young specialists. Moreover, more than 10 patients per month requiring palliative care/ambulatory consultation was noted in 40% of the physicians in the oncology/radiology group, while the ratio in the other services was of 8.7% (p = 0.049). Another finding showed that a percentage of 46.7% of the physicians in oncology/radiology services had training in the field of palliative care, while the lack of such training was detected in the other specialties (p = 0.007).

In oncology/radiology services, 46.7% of the physicians considered that they provided all the palliative care that the patients required, and 40% claimed that other resources (material or knowledge) would have been necessary in order to provide all the palliative care necessary to their patients. In contrast, as regards the other services, 56.5% of the respondents said that they did not provide this type of care (p = 0.028). The comparative analysis of the results of the two groups indicate that all the medical staff in oncology / radiology sections and 91.3% in the other sections considered training in the field of palliative care as being necessary in order to ensure good services (p = 0.667) and additional training in the field, according to the respondents, would bring an improvement in the quality of life of the patients (p = 0.827) (tab. IV).

As regards the main barriers to providing palliative care, approximately 47% of the staff who took part in the survey said that they have insufficient knowledge about pain control (p = 0.793) and 60% of the physicians in oncology / radiology sections and 47.8% from the other sections considered as the main barrier in the field of palliative care the reduced communication skills in interacting with the patient or his/her family (p = 0.687). In the oncology/radiology services, 86.7% of the physicians considered that they have insufficient time to provide all the care their palliative patients would require, while from the other services only 52.2% of the respondents said that they do not have enough time for palliative consultations (p = 0.031).

Great differences were noted in the percentage between physicians in oncology/radiology and the other services (73.3% *vs.* 21.7%) as regards the opinion on the patient's ignorance of his/her diagnosis as a barrier to providing palliative care (p = 0.005). No significant differences in percentage were found between the physicians' appreciation of hiding the diagnosis from the patient in providing palliative care as a barrier, although 1/3 of oncologists/ radiologists and only 13% of those belonging to other specialties considered the "conspiracy of silence" to be such a barrier. (p = 0.275). The lack of guidelines and protocols on palliative care was specified by 56.5% of the physicians in the group of other specialties and 33.3% of those in oncology/radiology, the percentage differences being statistically insignificant (p = 0.286).

TABLE IV

Statistical analysis of studied groups

Parameters	Oncology/ radiology group (n=15)	Other specializations group (n=23)	p values of Chi-square
Professional title			
Primary care physicians	5 (33.3%)	6 (26.1%)	0.676
Medical specialists	5 (33.3%)	6 (26.1%)	
Resident physicians	5 (33.3%)	11 (47.8%)	
Work experience in PC			
< 1 year	-	3 (13.0%)	**0.041**
1-3 years	9 (60.0%)	5 (21.7%)	
3-5 years	-	6 (26.1%)	
5-10 years	1 (6.7%)	3 (13.0%)	
> 10 years	5 (33.3%)	6 (26.1%)	
Number of PC cases/month			
None	-	-	**0.049**
1-10 cases	9 (60.0%)	21 (91.3%)	
11-30 cases	4 (26.7%)	2 (8.7%)	
> 30 cases	2 (13.3%)	-	
Training in PC	7 (46.7%)	1 (4.3%)	**0.007**
Benefiting of PC			
All the PC	7 (46.7%)	6 (26.1%)	**0.028**
Would have been necessary	6 (40.0%)	4 (17.4%)	
Not benefit	2 (13.3%)	13 (56.5%)	
Additional training in PC	15 (100%)	21 (91.3%)	0.667
Improvement in the quality of life of the PC patients	15 (100%)	22 (95.7%)	0.827

The frequency of physicians in oncology/radiology who remarked upon the lack of an interdisciplinary team for a holistic approach to address the cases was slightly higher compared to the other specialties (46.7% *vs.* 26.1%) (p = 0.338). It was noted that a percentage of 60% of the physicians in oncology/radiology declared that they are faced with a reluctant attitude of the patient or his/her family in the confrontation with the oncological disease, an aspect which was only found in 13% (p = 0.007) of the cases in the other specialties. The lack of knowledge or the lack thereof in relation to teamwork is considered to be a barrier to providing palliative care by 20-22% of the physicians surveyed (p = 0.781).

In the cases studied, approximately 47% of the physicians in both study groups considered administrative issues related to space, equipment, medication, etc., as barriers to ensuring palliative care (p = 0.793). The legislative gaps or poor legislation in the field of palliative care was remarked upon by 40% of the physicians in the group of oncology / radiology sections and by 26.1% of those from other specializations, the differences in percentage being statisti-

cally insignificant (p = 0.586). The burnout syndrome was mentioned only by 40% of the physicians in oncology/radiology (p = 0.004). Another aspect that resulted from the data studied showed that the lack of programs / initiatives dedicated to palliative care, in the cases studied, was mentioned rarely, with a slightly higher frequency in the group of physicians in the oncology / radiology sections (13.3% *vs.* 4.3%) (p = 0.698). Approximately 1/3 of the subjects in both study groups showed lack of and insufficient collaboration with other professionals in the hospital (p = 0.797) (tab. V).

TABLE V

Barriers to the provision of palliative care

Parameters	Oncology/ radiology group (n=15)	Other specializations group (n=23)	p values of Chi-square
Insufficient knowledge on pain control	7 (46.7%)	11 (47.8%)	0.793
Interaction patient / family	9 (60.0%)	11 (47.8%)	0.687
Insufficient time	13 (86.7%)	12 (52.2%)	**0.031**
Patient's ignorance of diagnostic	13 (73.3%)	5 (21.7%)	**0.005**
"Conspiracy of silence"	5 (33.3%)	3 (13.0%)	0.275
Lack of guidelines / IP protocol	5 (33.3%)	13 (56.5%)	0.286
Lack of an interdisciplinary team	7 (46.7%)	6 (26.1%)	0.338
Refractory patient attitude	9 (60.0%)	3 (13.0%)	**0.007**
Lack of teamwork	3 (20.0%)	5 (21.7%)	0.781
Ignorance of ethical issues	2 (13.3%)	2 (8.7%)	0.932
Administrative issues	7 (46.7%)	11 (47.8%)	0.793
Legislative gaps	6 (40.0%)	6 (26.1%)	0.586
Burnout syndrome	6 (40.0%)	-	**0.004**
Lack of programs providing care	2 (13.3%)	1 (4.3%)	0.698
Insufficient collaboration between specialists	5 (33.3%)	8 (34.8%)	0.797

As regards the usefulness of completing training in the field of palliative care, approximately 47% of the participants considered additional training to be useful for the development of communication skills with the patient or his/her family (p = 0.793), while the completion of professional training was considered useful for the development of teamwork according to 73.3% of the oncologists/radiologists and 87% of the physicians from the other specialties; however, the differences in percentage are statistically insignificant (p = 0.528). Approximately 1/2 of the subjects in both study groups considered such training to be useful in deepening their knowledge of medical ethics (p = 0.793). Moreover, approximately 1/3 of the subjects in both study groups believed that the therapy and control of other symptoms could be improved by completing professional training (p = 0.866). With one exception (an oncologist) the subjects wished to attend palliative care courses in the coming months (p = 0.827), while

13.3% of the physicians in the oncology/radiology group requested an advanced level of these courses.

It should be noted that all the medical staff in oncology/radiology and 95.7% in the other sections considered training in the field of palliative care to be necessary as regards the professional curriculum (p = 0.827), the duration of courses ranging between the study groups: 80% of the group of oncologists/radiologists preferred a duration of 3 months for the course, while the physicians in the other specialties mostly (60.9%) preferred a duration of 1 month (p = 0.007).

According to all the subjects surveyed, the extension of palliative care services was regarded as useful (tab. VI).

TABLE VI

The usefulness of completing training in the field of palliative care

Parameters	Oncology / radiology group (n=15)	Other specializations group (n=23)	P values of Chi-square
The usefulness of completing training in the field of PC			
development of communication skills	7 (46.7%)	11 (47.8%)	0.793
teamwork	11 (73.3%)	20 (87.0%)	0.528
medical ethics	8 (53.3%)	12 (52.2%)	0.793
therapy/ control of symptoms	5 (33.3%)	7 (30.4%)	0.866
The wish to attend PC courses	14 (93.3%)	23 (100%)	0.827
The utility to complete professional curriculum	15 (100%)	22 (95.7%)	0.827
The duration of courses 1 month 3 months 6 months	 2 (13.3%) 12 (80.0%) 1 (6.7%)	 14 (60.9%) 8 (34.4%) -	**0.007**
The utility of extension of PC services	15 (100%)	23 (100%)	**-**

CONCLUSIONS

In our study results showed that all the respondents have been confronted in their professional activity with cases of palliative care, which, in a hospital specialized in oncology, have an increased frequency. Throughout their professional activity, the respondents stated that they have provided palliative care to their patients, in their capacity of attending physicians, regardless of their level of training in the field. Moreover, the respondents admitted that their patients could often have benefited from a better palliative care, for which both deeper knowledge in the field, as well as additional material resources, would have been necessary.

The respondents stated that better training in the field of palliative care could contribute to enhancing the quality of life of their patients. For this purpose, the physicians surveyed shared the need to follow training courses in palliative care, claiming at the same time that a training module with duration of approximately 3 months within residency would be beneficial.

Finally, all the respondents considered the development and the expansion respectively of palliative care services to be useful.

PERICYTES IN HEALTH AND DISEASE

Pericytes also known as perivascular cells are contractile cells located on the external side of the endothelium in micro vessels. They communicate with endothelial cells via direct physical contact or through paracrine signaling pathways. These interactions are important for blood vessel maturation, remodelling, and maintenance. Pericytes are also known as Rouget cells after their discoverer, Charles Rouget, but the more suitable term pericyte (peri; around, cyte; cell) was coined by Zimmerman in the early 1920s, as the cells were found to wrap themselves around and along the vessel. They share many characteristics with smooth muscle cells that surround larger blood vessels as well as fibroblasts and myofibroblasts. Pericytes are of mesenchymal origin and have been shown to have mesenchymal stem cell properties capable of differentiating into other types of mesenchymal cells, including fibroblasts, osteoblasts, chondrocytes, and adipocytes. This article covers the areas of origin, structure, pericyte's interaction with endothelial cell, markers, functions; and role of pericytes in health and disease. It provides the current state of knowledge and thoughts for future investigations in these areas. Of interest is pericyte differentiation to other types of mesenchymal cells. Damage to a tissue initiates proliferation of fibroblasts, activation of fibroblasts to myofibroblasts, and the formation of new blood vessels. Endothelial cells and pericytes are interdependent, so failure of proper communication between the two cells can lead to numerous human pathologies. With time, a number of other functions have been attributed to pericytes, and it seems like we are now only starting to understand the complexity of this versatile, controversial and highly intriguing cell type (Munde PB, Khandekar SP, Dive AM et al. Pericytes in Health and Disease. International Journal of Oral & Maxillofacial Pathology. 2014; 5 (1): 02-07).

DENTAL STUDENTS' PSYCHOLOGICAL WELL-BEING DURING EXAMINATION PERIOD AND HOLIDAY (Abstract). **Introduction**: Psychological well-being is recognized as an important health component, which influences the behavior, ability to cope with stressful events, work performance, and generally the ability to achieve one's full potential. **Aim:** To comparatively assess the psychological well-being of dental students during the summer semester examination period and summer holiday. **Material and methods:** A single-arm, prospective study was conducted in second year dental students from the Faculty of Dental Medicine, Bucharest. The psychological well-being was assessed using the WHO-Five Well-being Index. **Results:** Students' psychological well-being was statistically significantly better during the summer holiday (median=19) than during the summer semester examination period (median=11.5), Z=3.69, p <.001. The perceived satisfaction regarding financial means, faculty colleagues, home, family and overall life satisfaction was the same during summer semester examination period and summer holiday, but it was significantly correlated with the WHO-Five Well-being Index score corresponding to the summer holiday, and no association was observed with the WHO-Five Well-being Index score corresponding to the summer semester examination period. **Conclusions:** Within the limits of this study, psychological well-being is likely to be negatively influenced, on a fairly large scale, by the semester examination period. Therefore, it is recommended to identify the most appropriate methods of examination with regards to the psychological load that might be a threat to the validity of students' evaluation. Additionally, training students about adequate coping strategies, designed as interventions at individual or group level, may be required. **Keywords:** DENTAL STUDENTS, MENTAL WELL-BEING, STRESS, PERSONAL SATISFACTION, EDUCATIONAL PROCESS, EDUCATION

Psychological well-being is as an important health component, rightly recognized by its inclusion in the definition of health by the World Health Organization. Well-being may influence the behavior, the ability to cope with stressful events, the work performance and generally the ability to achieve one's full potential (1-3).

In direct relation to the academic activities, the most stressful period for the students is the examination period, with high psychological demands related to taking multiple exams in a limited time-frame, these scores usually having the greatest

impact on their academic achievements for the respective semester. The marked stress during this period can adversely affect student's health and performance, with possible implications on the correctness of his/her evaluation (4, 5).

The aim of the study was to comparatively assess the psychological well-being of dental students during the summer semester examination period and summer holiday.

MATERIAL AND METHODS

Study design, settings and participants. A single-arm, prospective study was designed and implemented on a convenience sample formed by second year dental students from the Faculty of Dental Medicine, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania. The psychological well-being was assessed through a self-administered email questionnaire, filled in during summer semester examination period and during summer holiday. Enrolment was done in the 2014 summer semester examination period, on a voluntary basis. Repeater students were excluded. Informed consent was given by the participants when providing the email address to be sent the link to the questionnaire.

Variables. The main study outcome was the psychological well-being, that was assessed using the WHO-Five Well-being Index (WHO-5; WBI), developed by the Psychiatric Research Unit, Mental Health Centre North Zealand, Hillerod, Denmark, a World Health Organization Collaborating Centre. The Romanian language version was used, available on the website of Psychiatric Research Unit at the Mental Health Centre North Zealand. WHO-Five Well-being Index is a depression screening tool with good psychometric validity and sensitivity (6-8).It consists of a 5-item questionnaire, with a time frame of previous two weeks. Its interpretation is in accordance to the score obtained, that ranges from 0 to 25, with corresponding percentage score ranging from 0 to 100. A score below 13, corresponding to a percentage score below 50, or choosing answers with the minimum scores (0 or 1), indicates the need to perform a more detailed examination for the diagnosis of depression, the MDI questionnaire (Major Depression Inventory, World Health Organization) being recommended. For monitoring change, a difference of percentage score of 10 indicates a significant change in the psychological well-being (1, 6).

Other study variables were demographics (age, sex) and satisfaction with factors that may relate to psychological well-being (i.e. satisfaction with financial means, academic activities at faculty, faculty colleagues, home, general health, friends, family and overall life satisfaction).The latter were registered as self-rated satisfaction, using a 10 point numerical rating scale, with whole numbers (1 to 10 integers), that was defined by the extremes, from 1 (very unsatisfied) to 10 (very satisfied). The respondent was asked to select the number that best reflects their satisfaction level regarding the issues mentioned.

Data collection. Students were prospectively followed-up, the data being collected at baseline, during the summer semester examination period (T1) and during the summer holiday (T2). The summer semester examination period, according to the structure of the academic year of the Faculty of Dental Medicine of the University of Medicine and Pharmacy Carol Davila in Bucharest, had a 4 weeks length, from

07.06.2014 to 06.07.2014. Data was collected at T1 after two weeks from the beginning of the summer semester examination period, until it ended. Data was collected at T2 after three weeks from the completion of the summer semester examination period, after 28.07.2014, until the summer holiday ended.T2 moment was planned considering the need for a recovery period after the studied stress factor (semester examination period), considering the time-frame of previous two weeks of the WHO-Five Well-being Index, and also considering the possibility of student delay in responding the questionnaire.

Data collection was conducted online, by creating a questionnaire in Google Docs Form. This questionnaire was administered using the email address provided by the students. For the questionnaire completion on summer holiday (T2), two email reminders were sent to those who originally completed it in the summer semester examination period (T1). At T2, the respondents were no longer able to consult the previous responses, given at T1.

Data analysis. Statistical analysis was performed with SPSS software, version 13.The Wilcoxon signed-ranks test was used to evaluate differences in the scores of WHO-Five Well-being Index, at T1 and T2. Spearman's test was used for nonparametric correlation analysis between two factors. The significance level was set at $p<.05$.

RESULTS

Participants. Initially, a number of 39 second year dental students from the Faculty of Dental Medicine agreed to participate in this study and provided the email addresses. From these, 34 dental students responded to the email-delivered questionnaire during summer semester examination period (T1), corresponding to a response rate of 87%. They were aged between 19 and 24 years (mean and median - 20 years), of which more than half (n=22) were female. From the 34 dental students that responded to the questionnaire at T1, 20 students responded also to the same questionnaire in the summer holiday (T2),the response rate being 59%.They were aged between 20 and 24 years (mean=21 years; median=20 years), of which more than half (n=11) were female.

Psychological well-being. During the summer semester examination period (T1),the 34 dental students that responded to the questionnaire, obtained scores of WHO-Five Well-being Index varying from 4 (percentage score 16) to 20 (percentage score 80), with a mean of 12 (percentage score 49) and median of 12.5 (percentage score 50). According to the methodology of interpreting WHO-Five Well-being Index results, it was recommended to perform a more detailed examination for the diagnosis of depression in more than half of the analyzed students (n=20; 59%).

In the summer holiday (T2), the 20 students who completed the questionnaire again obtained scores of WHO-Five Well-being Index between 10 (percentage score 40) and 24 (percentage score 96), with a mean of 18 (percentage score 72) and median of 19 (percentage score 76). According to the interpretation methodology of WHO-Five Well-being Index results, it was recommended to perform a more detailed examination for the diagnosis of depression in only 3 (15%) of these students.

Using Wilcoxon signed-ranks test it was observed that psychological well-being is significantly better in the summer holiday (T2) than in the summer semester

examination period (T1)- in T2 median=19 (percentage score 76), in T1 median=11.5 (percentage score 46), Z = 3.69, p <. 001. A significant change of psychological well-being from T1 to T2, with differences of the value of the percentage score above 10, was observed in the majority of students (n=18; 90%).Seventeen students registered a psychological well-being improvement in T2, with positive changes of the percentage score of WHO-Five Well-being Index that ranged from 12 to 52 (mean, respectively median of percentage score change of 30, respectively 28) and one student registered psychological well-being decrease, with a negative change of the percentage score of WHO-Five Well-being Index of 12. The remained two students didn't register a significant change of their psychological well-being, one of them scoring the same at T1 and T2, and the other one scoring higher at T2, but the score difference from T1 was below the cut-off value of 10 for the percentage score of WHO-Five Well-being Index (Fig. 1).

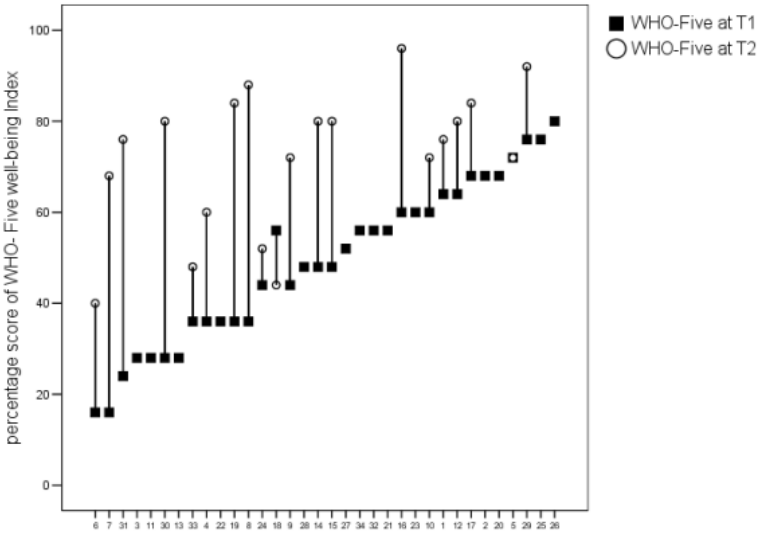

Fig. 1. Percentage scores of WHO-Five Well-being Index during summer semester examination period (T1) and summer holiday (T2)

Correlations between student psychological well-being and satisfaction with social and personal life-factors. Self-rated satisfaction with financial means, academic activities of faculty, faculty colleagues, home, general health, friends, family and his/her-own life overall was not different during the summer semester examination period (T1) and summer holiday and (T2), aspect analyzed using Wilcoxon signed-ranks test (table I). Even so, self-rated satisfaction with financial means, faculty colleagues, place of living, family and his/her-own life overall was strongly correlated with the score of WHO-Five Well-being Index during summer holiday (T2), and no correlations were found with the score of WHO-Five Well-being Index during summer semester examination period (T1) (tab. II).

DISCUSSION

These results suggest that dental students have a poor psychological well-being during summer semester examination period, much worse compared to the one during summer holiday period, during which the scores of WHO-Five Well-being Index are similar to the ones in general population (i.e. percentage score of approximately 70) (1, 6).

The significant difference of psychological well-being during semester examination period and holiday can be argued by the differences between them, as mental demand. The poor psychological well-being during summer semester examination period may be explained by the sustained mental demand, generally present during semester examination period in relation to the high number of exams taken in a relatively short time-frame. Also, during summer semester examination period it is possible that the students experience the highest stress levels, due to the cumulative effect of whole-year academic activities stress. In contrast, during summer holiday

the students have the longest period of vacation of the academic activities, which probably associates mental relaxation that promotes psychological change with improved well-being.

Academic examination stress has been related to various manifestations, such as higher level of anxiety, lower levels of self-esteem, somatic symptoms, eating disorders such as emotional eating, higher blood pressure (4, 9-11).Examinations are perceived as acting as unavoidable stressors, with possible negative consequences that depend on individual characteristics, such as personality traits, smoking habit, family medical history, like hypertension (2, 4, 9). Additionally, specific aspects related to the method of examinations have been related to the stress level. Among the aspects identified by medical students as contributing to exam anxiety, extensive course loads, long duration of exams, inadequate rest are included (12, 13).

Academic examination stress and its relation to psychological well-being should be especially considered in medical and dental students, considering that evidence show that they register higher prevalence of depression and anxiety, with levels of overall psychological distress consistently higher than in the general population, which could have an impact on their health, and also academic performance, dropout rates and professional development (3, 14, 15). Medical students register relatively frequently signs of burnout syndrome, as emotional exhaustion and depersonalization, which favors a higher degree of dysfunctional coping (5, 16, 17).In addition to this, there is limited evidence that indicates that the second year medical students experience the highest stress levels, exhibiting most frequently anxiety(18).

The results of this study also suggest that during the summer holiday, as a situation with a high degree of relaxation, there are many factors associated with student's psychological well-being, as self-rated satisfaction with their financial means, home (living conditions), family, faculty colleagues and overall life satisfaction. Even if the perception on these aspects is the same during the summer semester examination period, they are not correlated with the psychological well-being at that time. A possible interpretation of these results could be that during examination period students are extremely focused on the academic activities, other factors that typically influence their psychological well-being having a lower impact at that time.

It was noted that on the self-rated satisfaction matter, students were most dissatisfied with the academic activities of the faculty, even so, that was not related to their psychological well-being. These aspects may be in relation to their perceived opportunity to draw attention to issues that dissatisfy them about aspects related to the faculty, considering that this research was conducted in the academic settings. Additionally, these study results suggest that academic activities have an impact on students' psychological well-being, but their satisfaction with them is not a determining factor.

Study limitations are mainly related to the small convenient sample size, which may have affected the results. Also, a more accurate evaluation would include prospective follow-up during the entire academic year, in order to observe if indeed, poor well-being reaches its highest peak in the summer semester evaluation period, or it is the same with other evaluation periods. Additionally, comparison should be made

with other Faculties of Dental Medicine, in order to assess if results are not biased by specific particularities of this faculty. Even so, this research has the advantage of prospective follow-up, drawing attention to an issue that should be further investigated, considering the importance of psychological well-being and understanding its determinants.

CONCLUSIONS

Within the limitations of this study, psychological well-being is likely to be negatively influenced on a fairly large scale, by the semester examination period, with possible impact on students' health and performance on academic activities. Therefore, it is recommended to identify the most appropriate methods of examination regarding the psychological load that might be a threat to the validity of students' evaluation. Additionally, strategies for training students about adequate coping methods, designed as interventions at individual or group level, may be required.

IN VITRO COMPARISON OF THREE DIFFERENT IMAGE RECEPTORS FOR DETERMINING THE LENGTH OF ENDODONTIC FILES

The correct evaluation of working length is one of the most important conditions of successful endodontic treatment. Both digital and traditional radiographs have been used for these assessments. However, the accuracy of these methods is still controversial. The aim of this study was to evaluate the accuracy of endodontic file length measurements of E-speed radiographs, Digora storage phosphor plates, and Schick charge-coupled device sensors, with a secondary aim of assessing the influence of image enhancement on the measurement accuracy. Forty-seven extracted mandibular first premolar teeth were selected. ISO size 8, 10, and 15 files were inserted into each canal, and the files were fixed when the tip was seen at the apical foramen. The teeth were mounted in acrylic blocks and exposed using E-speed films, Digora storage phosphor plates, and Schick charge-coupled device sensors. Two radiologists and two endodontists measured the length of each file between the file stopper and tip on each image. Measurements were carried out on original and magnified images as well as on revealer images for Schick CDR. The actual lengths of the files were measured using a calipers to the nearest 0.01 mm and served as the "true length". Repeated measures analysis of difference and Tukey honestly significant difference tests were used to analyze the data ($P < 0.05$). E-speed films were superior to digital systems for the measurement accuracy of the size 08 file ($P < 0.05$). Revealer images gave equivalent results with E-speed films for the measurement of the size 10 file ($P > 0.05$). The most accurate results were obtained with the size 15 file regardless of the image receptor ($P > 0.05$). Size 15 or larger files should be used for endodontic working length determinations. Revealer images gave equivalent results with E-speed films and may be utilized for determining the file length of size 10 files (Betul Ilhan, Ilgın Akcay, Nesrın Dundar. In vitro comparison of three different image receptors for determining the length of endodontic files. *Journal of Dental Sciences* 2014; 9(4): 345-350).

LASER ASSISTED VERSUS CONVENTIONAL FRENECTOMY IN ORTHO-DONTIC PATIENTS (Abstract): **Aim**: The aim of this study was to evaluate the laser assisted frenectomies versus conventional ones from the technique and the post-op recovery point of view. **Material and methods**. We selected a sample population of 20 patients with thick, low inserted maxillary midline frenum and midline diastema. We randomly divided the sample population into two groups named A and B with an equal number of patients. Patients included in group A were treated with conventional technique while patients included in group B were benefited of laser assisted frenectomy. **Results and discussion**. Our findings showed that laser assisted procedure was much faster to perform than the conventional one due to the easier protocol, absence of sutures and better cooperation from the patient side. In the same time it provided a better comfort degree to the patient and an accelerated healing**. Conclusions**. Laser assisted technique for maxillary midline frenectomy in conjunction with orthodontic treatment proved to be superior to the conventional one because it saves time; it's minimally invasive and provides a better cooperation with the child. **Keywords:** MAXILLARY MIDLINE FRENUM, DIASTEMA, FRENECTOMIES, DIODE LASER.

After Carranza et al a frenum is a fold of mucous membrane, usually with enclosed muscle fibers that attach the lips and cheeks to the alveolar mucosa and/or gingiva and underlying periosteum.

The same authors say that it becomes a problem if the attachment is too close to the marginal gingiva. Carranza at al claim that this anatomic situation may be a genetic condition of the individual or the result of recession of the gingival margin reaching the area of the frenum. Tension on the frenum may pull the gingival margin away from the tooth creating a periodontal problem. (1)

After Edwards the pretreatment relationship between a thick and low inserted maxillary midline frenum and a midline diastema showed a strong, but not absolute, correlation. (2)

The aim of this study was to evaluate the laser assisted frenectomies versus conventional ones from the technique and the post-op recovery point of view.

MATERIAL AND METHODS

We selected a sample population of 20 patients with thick, low inserted maxillary

midline frenum and midline diastema.

The average age of the sample population was 10.4 years while 55% were females and 45% males.

All patients included in the current research needed frenectomy as an adjuvant therapy to the orthodontic treatment (Fig. 1).

We randomly divided the sample population into two groups named A and B with an equal number of patients.

Patients included in group A were surgically treated through the conventional frenectomy technique using a scalpel and 4.0 silk for suture.

Patients included in group B received laser assisted surgical removal of the frenum using a diode laser with the wavelength of 940 nm and a optical fiber with the diameter of 400 μm (Fig. 2).

In order to increase the cutting effect of the laser the fiber was previously activated. (fIg. 3a-3b).

The laser was set at 1.5 W energy in CP2 and throughout the procedure the tissue was irrigated with a saline solution in order to avoid the overheating (Fig. 7).

Fig. 1. Initial aspect of the maxillary

Fig. 2. Optical fiber

Fig. 3a. Fiber activation

Fig. 3b. Complete diode laser equipment

All surgical procedures were done under infiltration anesthesia with articaine and by the same team.

RESULTS AND DISCUSSION

Suter at al. claim that closure of the maxillary midline diastema with a prominent frenum is more predictable with frenectomy and concomitant orthodontic treatment than with frenectomy alone. (3) This is why an efficient and minimally invasive management of maxillary midline frenectomy is desirable especially in children.

Our results showed that during laser assisted surgery the bleeding was nearly absent and the young patient had a better degree of comfort (Fig. 4). In the same time patients included in group B didn't need suture in order to prevent the reattachment of frenum.

Healing process was faster in the group that benefited from laser assisted surgery compared to conventional technique. (fig. 5) This fact is in accordance with fundamental research results from literature that emphasized the morphological differences identified at the gingival epithelium level and subjacent lamina propria support the value of laser therapy, stimulating an improved healing of the damaged tissues. The patients included in group B presented as well significantly diminished post operative pain and absence of edema (Fig. 6).

Fig. 4. Immediate post-op aspect after laser surgery

Fig.5. Three days follow-up

Fig. 6. Facial aspect at 3 days follow-up

Fig. 7. Laser settings

Other studies proved that the overall perception of young patients towards laser assisted periodontal surgery was very high and this is a means of reducing operating time and anxiety caused by the surgery itself. (5)

Our findings showed that laser assisted procedure was much faster to perform than the conventional one due to the easier protocol, absence of sutures and better cooperation from the patient side.

Due to the vaporization effect of the laser at the cellular level the reattachment rate of the frenum is significantly reduced and will provide a faster orthodontic tooth movement for closing the diastema.

The ideal approach for successfully treating this kind of cases is the interdisciplinary one with a tight cooperation between orthodontist, periodontist, oral surgeon and general practitioner.

CONCLUSIONS

Laser assisted technique for maxillary midline frenectomy in conjunction with orthodontic treatment proved to be superior to the conventional one because it saves time; it's minimally invasive and provides a better cooperation with the child.

The laser assisted frenectomies proved that the reinsertion rate of the midline frenum was minimal (Fig. 8-9).

NEW HYDRAZONES OF FERULIC ACID: SYNTHESIS, CHARACTERIZATION AND BIOLOGICAL ACTIVITY (Abstract): The ferulic acid (4-hydroxy-3-methoxy-cinnamic acid) is a phenolic compound with important antioxidant effects and which nowadays is being extensively studied for his potential indications in inflammatory and neurodegenerative diseases, hypertension, atherosclerosis, etc. **Aim**: The synthesis of new ferulic acid compounds with potential antioxidant activity. **Material and methods**: The synthesis of the designed compounds was performed in several steps: (i) the obtaining of ferulic acid chloride by reacting of ferulic acid with thionyl chloride; (ii) the reaction between the ferulic acid chloride and hydrazine hydrate 98% to obtain the ferulic acid hydrazide; (iii) the condensation of ferrulic acid hydrazide with various benzaldehydes (2-hydroxy/3-hydroxy/4-hydroxy/2-nitro/3-nitro/4-nitro/2-methoxi/ 4-chloro/4-fluoro/4-bromo-benzaldehyde) resulting the corresponding hydrazones. **Results**: The structure of the synthesized compounds was confirmed by FT-IR spectroscopy and the evaluation of antioxidant potential was achieved by determining the total antioxidant capacity and reducing power. **Conclusions**: In this study new hydrazones of ferulic acid have been synthesized, physic-chemical and spectral characterized. The evaluation of antioxidant potential using *in vitro* methods showed the favorable influence of the structural modulation on the antioxidant effects of ferulic acid. **Keywords**: FERULIC ACID, HYDRAZONE, ANTIOXIDANT ACTIVITY

One of the most studied biological effects of ferulic acid derives from its antioxidant properties. Due to the phenolic structure, ferulic acid could easily form a phenoxy group, stabilized by resonance and which explains its antiradical effect. This allows the ferulic acid to protect the DNA and the lipids from the oxidation caused by the reactive oxygen species (ROS) (1, 2). Based on its antioxidant effect, ferulic acid can be effective in the prevention and treatment of several diseases where oxidative stress plays an important role like: Alzheimer's disease, diabetes mellitus, cancer, hypertension and atherosclerosis. At the same time the involvement of oxidative stress in inflammation suggest that ferulic acid may also be effective in the treatment of inflammatory diseases. Moreover, the specific structure gives ferulic

acid a strong UV absorption ability, making it a powerful skin protecting agent (3). Based on these considerations we have proposed the synthesis and biological evaluation of new ferulic acid hydrazones. Through their antioxidant potential, these compounds can be used in the protection of biological systems from oxidative stress.

MATERIAL AND METHODS

Ferulic acid, thionyl chloride, hydrazine hydrate, aromatic aldehydes (4-fluoro/4-bromo/ 4-chloro/ 2-nitro/ 3-nitro/ 4-nitro/2-hydroxy/3-hydroxy/4-hydroxy/2-methoxy-benzaldehy-de), organic solvents (*p.a.* quality) and standard reagents used for the antioxidant tests were purchased from Sigma Aldrich Company and Fluka Company. All the solvents and the reagents were used without prior purification. TLC plates silica gel 60 F_{254} from Merck Company were used for monitoring of the chemical reactions.

Chemistry

Synthesis of ferulic acid hydrazones. The ferulic acid was reacted with thionyl chloride to give the corresponding acid ferulic chloride. This intermediate was treated in the next step with hydrazine hydrate (98%) when the ferulic acid hydrazide it was formed, which by condensation with various aromatic aldehydes (2-hydroxy/3-hydroxy/4-hydroxy/2-nitro/3-nitro/4-nitro/2-methoxi/4-chloro/4-fluoro/4-bromo-benzaldehyde) led to the corresponding hydrazones (fig. 1). The synthesis of the designed compounds was performed by adapting some methods from literature for similar compounds (4, 5).

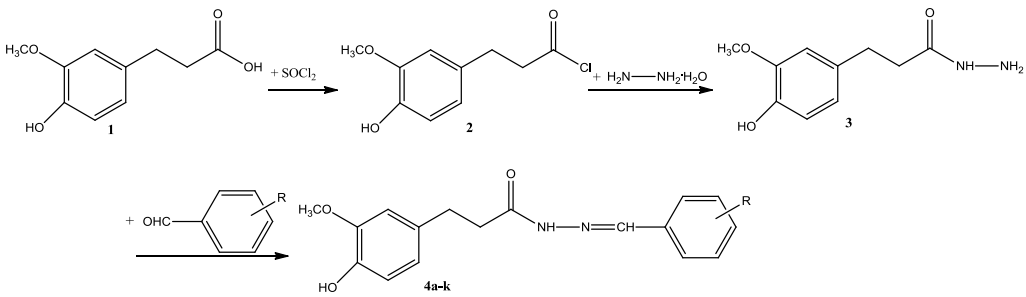

Fig. 1. The synthesis of new ferulic acid hydrazones

General procedure for the synthesis of ferulic acid hydrazones. In the first step thionyl chloride (0.15 mol, 11 mL) it was added dropwise and under stirring over ferulic acid (0.025 mol, 5 g). The reaction mixture is maintained in oil bath at a temperature of 50 ^{0}C for 4 hours. At the end of the reaction, the solution was concentrated in order to remove the excess of thionyl chloride. In the second step, over dry ferulic acid chloride (0.05 mol, 10.62 g), it was added drop wise hydrazine hydrate solution 98% (0.25 mol, 12.37 mL). The reaction mixture was maintained in ice bath for 2 hours, after which on water bath at room temperature for another 2 hours under continuous stirring. At the end of the reaction 15 mL of cold water was added and the resulting precipitate was filtered off and dried at room temperature. In the last step,

the ferulic acid hydrazide (0.015 mol, 3 g) was suspended in 100 mL of absolute ethanol and then it was added a few drops of glacial acetic acid and 0.015 mol of aromatic aldehyde (2-hydroxy/3- hydroxy/4-hydroxy/2-nitro/3-nitro/4-nitro/2-methoxi /4-chloro/4-fluoro/4-bromo-benzaldehyde). The reaction mixture was heated under reflux on water bath from 13 to 20 hours. The reaction was monitored by TLC, using a mixture of ethyl acetate: methanol: acetone: water = 5: 2: 2: 1 as solvent system.

Characterization by FT-IR spectroscopy. The FT-IR spectra of the synthesized compounds, intermediate and final compounds, were recorded using a Fourier transform spectrometer, ABB-MB 3000 FT-IR MIRacle^{TM} Single Bounce ATR-crystal ZnSe and the spectral range studied was in the range of 4000-500 cm^{-1}, at a resolution of 4 cm^{-1}, being carried out 16 scans for each sample. The spectra were interpreted using Horizont program MB^{TM} FT - IR.

Antioxidant assays

Determination of total antioxidant capacity. The total antioxidant capacity of the synthesized compounds was evaluated using phosphomolybdenum method following the protocol described by Cacic et al. (2010) with some minor modifications. The samples were dissolved in DMSO (dimethyl sulfoxide) in order to form a stock solution with the concentration of 2 mg/mL. From the stock solution it was taken different volumes (10 µL, 20 µL, 40 µL, 60 µL) and then added DMSO to have a final volume of 200 µL sample. Over the resulting mixture it was added 2000 µL reagent (28 mM phosphate, 4 mM ammonium heptamolybdate, 0.6 M sulfuric acid). After a preliminary stirring, the solutions were incubated at 95^0C for 90 minutes, cooled in cold water and centrifuged at 4,600 rpm for 15 minutes. The supernatant was separated and the absorbance was read at a wavelength of 695 nm against a blank consisting of 2000 µL reagent and 200 µL DMSO. For each compound it was calculated effective concentration 50 (EC_{50}) by linear regression and ascorbic acid (2 mg/mL) was used as a positive control. All determinations were performed in triplicate and the results were expressed as arithmetic average ± standard deviation (SD).

Reducing power. Reducing power of the synthesized compounds was measured by the method described in the literature (7) with some modifications. Samples for analysis were dissolved in DMSO to give stock solutions with concentrations of 2 mg/mL. Over 1 mL sample of various concentrations obtained by serial dilutions of the stock solution (2 mg/mL) 1 mL of phosphate buffer (pH 6.6) was added. After vigorous stirring 1 mL of 1% potassium ferricyanide was added. The homogenous mixture was incubated for 20 minutes at 50 ^{0}C, then cooled in cold water and added 1 ml 10% trichloroacetic acid. After vigorous shaking the samples were centrifuged at 4500 rpm for 15 minutes. To 1 mL of the supernatant it was added 1 mL of doubly distilled water, and 0.2 mL of 0.1% ferric chloride. After 5 minutes the absorbance was read at the wavelength of 700 nm against a blank (the reaction mixture without the sample). For each compound it was calculated effective concentration 50 (EC_{50}) by linear regression and ascorbic acid (2mg/mL) was used as a positive control. All determinations were performed in triplicate and the results were expressed as arithmetic average ± standard deviation (SD) (8).

RESULTS AND DISCUSSION

Physical-chemical and spectral characterization

The ferulic acid hydrazones are crystalline powders colored in different shades which vary from light yellow to bright brown, very slightly soluble in dimethylformamide (DMFA), dimethyl sulfoxide (DMSO), partially soluble in absolute ethanol, methanol, chloroform, acetone, dioxane, and insoluble in distilled water and diethyl ether. The physico-chemical characteristics and the FT-IR bands are listed in table I. The presence of the absorption band characteristic to hydrazone bond (CH=N), confirms structure of the synthesized compounds.

TABLE I

Physico-chemical and spectral characteristics of ferulic acid hydrazones (4a-k)

Comp.	R	Mol. weight	Yield (%)	m.p. (^{0}C)	FT-IR characteristic band (cm^{-1})

Antioxidant assays.

Determination of total antioxidant capacity. This method is based on the reduction of Mo^{+6} to Mo^{+5} by the tested compounds followed by the formation of the phosphate/Mo^{+5} green complexes at acidic pH. From the obtained results (tab. II, fig. 2) it can be observed that the tested compounds are more active than ferulic acid with the exception of **4c** and **4j**. The hydrazone resulted from the condensation of benzaldehyde with ferulic acid hydrazide (compound **4k**) is 1.32 times more active than ferulic acid. Regarding the influence of radicals which substitute the aromatic ring, it was observed that the most favorable influence was exerted by -OH(2),-NO_2(2) and -F(4) radicals, the corresponding compounds (**4g, 4d, 4a**) being 1.80, 1.23 and 1.11 times more active than the unsubstituted derivative (**4k**). The studied compounds have been, however, less active than the ascorbic acid used as positive control.

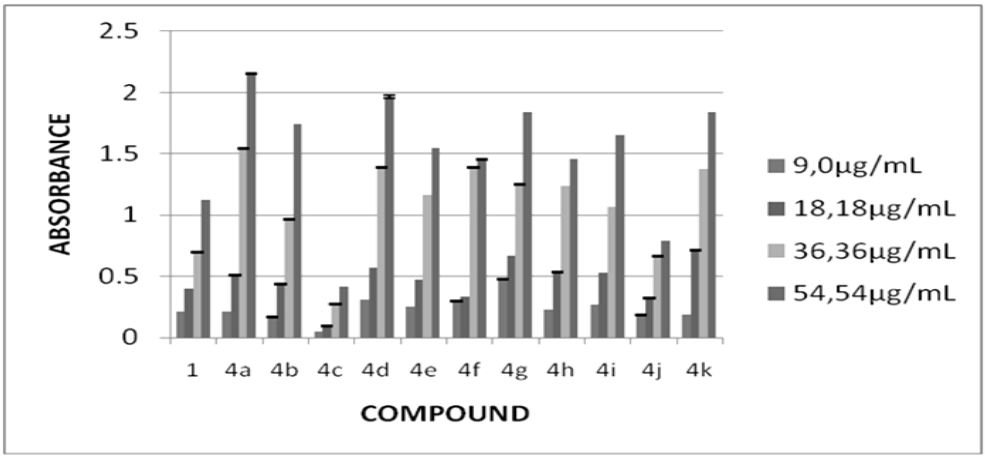

Fig. 2. The absorbance value of ferulic acid hydrazones (**4a-k**) at different concentrations

TABLE II

The total antioxidant capacity (EC_{50}, mg/mL) of ferulic acid hydrazones (4a-k)

Compound	EC_{50} µg/mL	Compound	EC_{50} µg/mL	Compound	EC_{50} µg/mL
1	23.40 ± 0.03	**4d**	14.30 ± 0.03	**4h**	19.01 ± 0.01
4a	15.78 ± 0.04	**4e**	17.72 ± 0.05	**4i**	16.62 ± 0.01
4b	18.65 ± 0.05	**4f**	16.94 ± 0.05	**4j**	32.87 ±0.12
4c	65.17 ± 0.11	**4g**	9.77 ± 0.03	**4k**	17.64 ± 0.01
ascorbic acid 5.17 ± 0.19					

1 = ferulic acid,

* the EC_{50} values are the average of three determinations ± standard deviation

Reducing power. The studied compounds have the capability to reduce Fe^{3+} from the ferricyanide complex to Fe^{2+}, changing the color of the test solution from

yellow to green depending on the reducing power of each compound. Derivatization of ferulic acid increases the reducing power, the tested compounds being more active than ferulic acid, except the compound resulting from the condensation of 4-bromobenzaldehyde (**4c**) (fig. 3, tab. III). The hydrazones resulting from the condensation of benzaldehyde with ferulic acid hydrazide **(4k)** was found to be 1.2 times more active than ferulic acid. Regarding the influence of radicals which substitute the aromatic ring it was observed that the most favorable influence was exerted by the -OH(3), the corresponding compound (**4h**) being 1.22 times more active than the unsubstituted derivative (**4k**). The compounds studied have been, however, less active than the ascorbic acid used as a positive control.

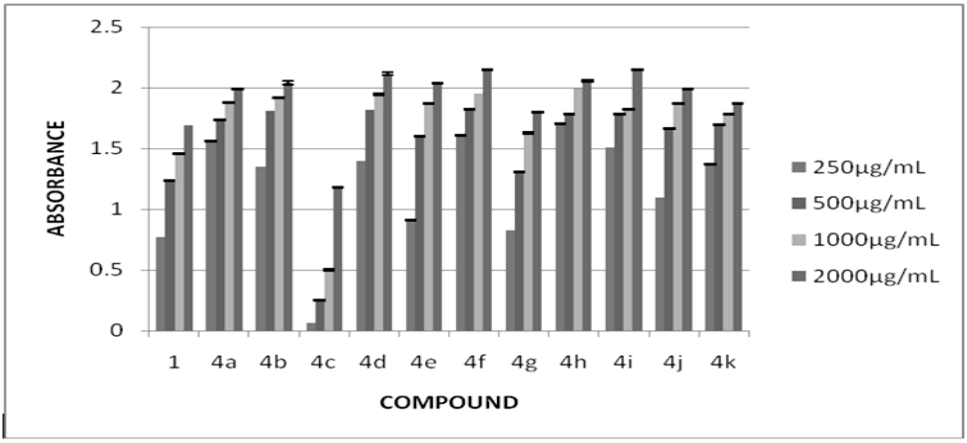

Fig. 3. Absorbance value of hydrazones of ferulic acid (**4a-k**), at different concentrations

TABLE III

The reducing power (EC_{50}, mg/mL) of ferulic acid hydrazones (4a-k)

Compound	EC_{50} µg/mL	Compound	EC_{50} µg/mL	Compound	EC_{50} µg/mL
1	189.88 ± 1.52	**4d**	153.92 ± 0.03	**4h**	128.41 ± 0.36

ascorbic acid 5.87 ± 0.24					

1 = ferulic acid,* the EC_{50} values are the average of three determinations ± standard deviation

CONCLUSIONS

Some new hydrazones of ferulic acid have been synthesized and optimal conditions of reaction were established for obtaining compounds with high yields and advanced purity. The synthesized compounds have been characterized by their physical constants (melting point, yield,

molecular formula, molecular weight, solubility in different organic solvents) and their chemical structure was confirmed using FT-IR spectroscopy.

It was also assessed the antioxidant potential using *in vitro* methods. All the tested compounds showed total antioxidant capacity and reducing power appreciable in reference with ferulic acid, which confirms the favorable influence of structural modulation performed on the antioxidant effects of ferulic acid.

MALPRAXIS RISK MANAGEMENT IN IMPLANTOLOGY

I.C. Lupu[1], Norina Consuela Forna[2]
University of Medicine and Pharmacy, "Grigore T. Popa"- Iasi
Faculty of Dental Medicine
1. Discipline Public Health and Oral-Dental Management
2. Department of Implanto-Prosthetic

MALPRAXIS RISK MANAGEMENT IN IMPLANTOLOGY (Abstract): In present practice there is an increased demand from patients for prosthetic implant restoration solutions. At the same time one can notice a possible vulnerability regarding allegations of malpractice, as evidenced by the growing number of complaints of malpractice also maintained by negative reports, frequently incomplete or incorrectly documented from the press. This should require practitioners to have a professional attitude. **Keywords**: MALPRAXIS, IMPLANTO-PROSTHETIC, DENTAL PRAXIS, INFORMED CONSENT

The growing number of Romanian dentists on the medical market led to a reorientation of health services optics from providing optimal therapeutic solutions to focusing on patient satisfaction, for more profit. This led to a compromise in the application of therapeutic solutions along with a poor doctor-patient communication that has led to increased incidence of malpractice, which currently has strong media coverage. All this led to a loss of the patient`s confidence in the dentist and the quality of treatment. The patient`s reluctance towards the medical act is enhanced by continuously increasing rates of medical services so there will be much higher claims about the final result. His dissatisfaction may lead not only to the negative publicity attached but also to punitive professional claims, moral and material damages on grounds of malpractice.

The definition of malpraxis (lat. malus „bad" + gr. praxis „practice") = malpractice is the professional error committed in the exercise of medical or medical-pharmaceutical act, generating damages on the patient, involving civil liability of medical personnel and medical products and services provider, healthcare and pharmaceuticals (according Law No. 95/2006 on healthcare reform).

Dentists must responsibly provide patient care according to the standards of competence and behavior that they have assumed when choosing this profession. The dentist needs to improve and promote the patient`s oral health so as to respect his dignity, autonomy rights. Also, the practice of the profession must take place effectively and with minimum risks for the physician. Knowledge and compliance with the legislation is, from this point of view, of the utmost importance and protects the doctor, giving him the opportunity to adopt an approved therapeutic behavior which reinforces his professional dignity.

Legal regulations directly concerning the practice and conduct of the physician in our country are:

- Law No. 95/2006 on healthcare reform, as modified - art. 649 et seq.
- Order No. 482/2007 of the Minister of Public Health - "Rules for the application of Title XV: civil liability of medical personnel and medical products and services provider, healthcare and pharmaceuticals" in Law no. 95/2006 on healthcare reform. Law no. 46/2003 of patient rights
- Ministry of Health Order no. 386/2004 on approving the Implementation rules of patients' rights law no. 46/2003.
- Deontological Code of the dentist.

These rules should consider the European standards and norms to which Romanian legislation must comply with.

A number of vulnerable aspects related to malpractice that stand out and that should be taken into account are strictly medical related : a standard guide of diagnosis and treatment, the patient's informed consent, confidentiality, patient access to their medical information, patient access to non- discriminatory treatment, access to media, the right to a second opinion, limiting to their own specialty. The minimal documentation necessary in a medical office at present is the sheet of treatment, the informed consent, the general status questionnaire, the registry of consultations and treatment, the laboratory sheet, various patient agreements, internal rules displayed, the job description for employees.

Prosthetics on implants involves particular issues compared to other types of treatment in practice. This is a new, modern therapeutic solution, expensive for the patient, requiring special training and equipment from the doctor.

A first step in therapeutic success is the suggestive phrase "know the patient and his limits." The clinician should professionally evaluate the patient`s general condition, his clinical situation and decide whether the chosen therapeutic solution is up to the patient`s expectations. This requires gathering information. Retrieving general patient data is an operation that takes time and can be performed even by the latter, using a standard form that the patient fills in the waiting room along with a questionnaire where the general condition will be checked, if he suffers from other diseases, if he is under a treatment that may interfere with dental therapy. General status questionnaire must be completed thoroughly, as some medical history are absolutely not suitable for surgery such as face bone radiotherapy, bisphosphonate treatment with immunosuppressives, recent myocardial infarction (MI), certain psychiatric disorders and drug abuse. Other conditions are considered negative factors for osseointegration of implants: some forms of diabetes, multiple allergies, cardiovascular risk, a general malaise, etc. Drinking and smoking are also included here. At this point the doctor will decide if the patient needs to obtain blood marker values that help to form a complete overview of his medical condition.

The patient`s record is then completed along with the doctor with specialized data that should include the initial oral situation, diagnosis, prognosis, the description of each performed maneuvers, when it was performed, medical history, prognosis and initial costing, name and signature of the physician. After diagnosis and treatment plan development by the doctor, the patient must be explained to, as to a reasonable person, the treatment and outcomes proposed as well as the accidents and complications that may arise and provisionally

estimated costs. Subsequently, the patient must give his consent for the treatment by signing his informed consent, compulsory in writing.

*The patient`s informed consent is necessary for the application of the therapeutic solution.* It can take multiple forms: as a questionnaire with categories to be filled or checked or in the form of a declaration summarizing the risks and complications that may occur. It includes several parts: the patient`s personal data, that will be listed both in the treatment sheet, register of consultations and treatment and general status questionnaire; a part briefly describing the medical act, then the name and specialty of the medical team, another part stating that the patient has been explained the overall condition, diagnosis, prognosis, risks and complications that may occur after treatment and the cost estimates, risks that may occur if the patient does not follow the medical instructions. It will include information about: the legal representative for minors, or persons without discernment, consent for the collection, preservation and use of biological samples, the agreement for further investigation (dental records), information on the rules of the cabinet, the right to a second opinion. A section or important part is the answer to mental illnesses which the patient may present (for some conditions agreement becomes null), and then the name and signature for the agreement or disagreement of the patient or legal representative. Also the legal acts underlying the necessity of its conception and completion must be mentioned. The only situation where there is no need for the patient`s consent is life threatening situations, in which case an emergency report will be completed. In this report the circumstances, the initial state of the patient, the therapeutic emergency approach and general state after overcoming the emergency will be mentioned.

The patient`s correct information by the physician in order to obtain their consent for treatment requires communication skills from both sides. The explanation must be given by the use of a language specific for a 14 year old child, at a reasonable scientific level of patient comprehension. The patient is the only one able to decide what risks he is willing to take. In most dental offices informed consent forms are of a general nature. It is useful to develop this especially designed form for implant-prosthetic solution so as to eliminate the suspicion or the possibility that consent is considered to be formal(1, 2).

Various types of agreement are useful in practice such as: patient consent for the communication of medical data, patient agreement on the participation in higher education, agreement on communicating medical documents.

Rules of internal order are recommended for the patients to be displayed where several items are specified, such as: rules about conduct, scheduling patients, providing medical information, media access.

Medical offices, clinics, need to respect the confidentiality of patient data, here including the whole medical team: doctors, nurses, technicians. According to current laws, the physician may not disclose to any other person than the patient, data about its health. Information on the patient`s health, results of investigations, diagnosis, prognosis, treatment followed, and any information that could link the identity of a person of a certain medical information is strictly confidential, obligation of confidentiality continuing even after the patient's death. The physician / medical staff

are not allowed to provide information on the nature of the above even to the family or friends of the patient, without its consent. In these circumstances, doctors are not allowed to communicate medical data about patients to third parties.

The principle of autonomy is reflected in the practices in the obligation to ensure patient access to personal health data. At the patient`s request copies of sheet treatment and original dental scans will be made available to them (digital copies will be kept in the archive).

According to the law it is forbidden to discriminate between persons in similar circumstances on the basis of race, sex, age, ethnicity, social or national origin, and religion, political or personal dislike.

Medical malpractice. Relationship with the media is a controversial topic in the medical world, largely due to negative media campaign against Romanian medical activity and the perception of journalists by the medical world in an utterly unfavorable way. A Kompass Media report monitoring printed media revealed that during the 1 July 2007 - 17 September 2007 period, 97 articles were classified by the press as cases of "medical malpractice." All items monitored recounted discontents and complaints from patients, the tone used by publications being accusatory to the doctors, even without confirming the existence of a medical fault. According to legal regulations, no patient can be photographed or filmed in a medical facility without his express consent (without infringing the rules and regulations of the medical unit). The doctor may refuse or reschedule the meeting with the media, it is recommended to be retained in comments and treat everything with a detached tone and even positive if possible.

Of particular importance is the malpractice insurance that each of the medical staff has. It is advisable to negotiate the terms of the insurance coverage so as to obtain both material and moral damage, and cover more disputes over a longer period of time (3, 4).

The development of contracts between offices and suppliers of materials and equipment should also be considered, the certificate attesting that they have European compliance, the contracts between clinics and dental labs, in stating that prosthetic pieces have certificates of conformity and will also respect the confidentiality of patient data.

Of particular importance in supporting a correct diagnosis and optimal therapeutic option are intra and extra oral clinical examinations, followed by a series of paraclinical investigations. This can be achieved by making the initial extra oral photos that capture the smile line, the shape of the lips, and of the face, and intraoral that captures the initial dental status and the possible initial degree of dental hygiene. At the same time the dentist has to make a map of the periodontium, the periodontal probing, which is attached to the treatment sheet. Next the study designs should be made that record oral initial status and on which the mock-up of future dentures can be achieved. This mock up done in the lab is to help patients understand what the future prosthetic will be like. The physician should record the type of occlusion and the potential occlusal para functions.

Analogical or digital intra and extraoral dental X-rays, CBCT (cone bean computer tomography) are required for implant solutions. With digital radiological images processed using dedicated 3D software the volume and quality of jaw bone can be evaluated, also the distances to certain

anatomical landmarks, it can simulate various types and sizes of implant insertion axis and also determine the form of the surgery guide. Your doctor will decide if additional surgical maneuvers will be required for bone adjustment. Various makeovers will be recommended in order to establish an optimal pre implantation oral status. Digital prints together with intraoral scanners helps the doctor get a final prosthetic, close to that simulated on the computer and the mock-up. "Electronic" sheets and dedicated programs facilitate virtual presentation of the operating time and the final form of prosthetic reconstruction. It also helps in maintaining an accurate record of the patients and a close hospitalization. Hospitalization of patients should be made according to the needs of each patient so as to prevent any post therapeutic complications. Patients should understand the importance of these periodic checks, when the physician makes an assessment of oral and implant tissue, of the occlusal changes and a radiological examination of implant osseo integration (5).

Implantology is found at the intersection of two specializations: the dental alveolar surgery and prosthetic surgery. Hence, the need for the physician to achieve particular theoretical and surgical skills. Therefore, in the present practice in our country doctors are required to obtain a certificate of competence and a diploma in implantology, at which it is recommended the addition of certificates on various surgical skills. But of equal importance is the prosthetic stage, which, by unusual stress, can lead to loss of implants. Therefore, training in prosthetic rehabilitation is a very important issue, prosthetic on implants being different than on natural teeth.

To prevent potential disagreements with the patient, the doctor should mention that there are no guarantees of success and strength over time for certain maneuvers and dentures. Also it is necessary to consider the patient's expectations related to aesthetics, functionality, adaptation or resistance to various therapeutic solutions, those often going beyond the possibilities of achievement. Full preparation of the practitioner, choosing the therapeutic solution according to the particular clinical case, provides the premises for a successful treatment. Increased attention on a correct, sincere,disinterested communication, along with providing all the information from both sides, creating a partnership, may decrease the risk of conflict situations that have no relation to malpractice but that the patient perceives them as such.

DENTAL PATIENTS' ATTITUDES TOWARDS INFECTION CONTROL (Abstract): The level of the patients' education for health is increasing as their concern for protection during the medical treatment. The aim of this study was to assess the attitudes of the dental patients towards infection control protocols in the dental office. Material and methods: A questionnaire-based study was initiated including 210 patients aged between 16 and 68 years. Data was processed using *SPSS 14.0* and analyzed by age, gender and level of education. Results: 82.6% of the patients trust the medical staff to protect them against the spread of infection. Female subjects are twice as interested in the follow up of infection control procedures as males (53.4% respectively 25.2%). The diseases considered by the patients as presenting a high risk of transmission during dental treatment are: hepatitis B, HIV infection, hepatitis C, tuberculosis and hepatitis A. The subjects require the dentist to wear rubber gloves (89,2%), masks (61.5%) and glasses (45.5%). Conclusion: The involvement of the dental patients in their own treatment is essential in order to increase the safety and quality of the dental procedures. Keywords: DENTAL PATIENTS, SAFETY, INFECTION CONTROL

The control of infection transmission represents an important goal of the modern a safe environment for the protection of the dentistry. Using the best and updated guidelines and recommendations the dentist has the duty to ensure dental team and patients which must be involved in their own health care regarding the diagnosis, investigations and treatment (1, 2). In order to raise the public awareness on the benefits of the safety protocols it is very important to implement effective infection control programs involving the dental patients (3).

MATERIAL AND METHODS

In order to assess patients' compliance and attitudes towards infection control procedures a questionnaire-based survey was initiated involving 210 patients aged between 18 and 65 years. The confidential questionnaire included 20 questions on the patients' perception about the infection risk and infection control strategies during the dental procedures. Data was analyzed by age, gender and level of education using *SPSS 14.0* (levels of statistical significance were set at $p<0.05$).

RESULTS

Of the study group 130 (62%) were women and 80 (38%) men. In terms of education level and occupation 62 (29.6%) of patients had a high education, 66

(31.4%) a medium education, 58 (27.9%) were students and 24 (11.1%) were retired.

The results of the study reveal that the diseases considered by the patients as presenting a high risk of transmission during dental treatment are: hepatitis B (62.3%), HIV infection (47.0%), hepatitis C (44.3%), tuberculosis (12.4%) and hepatitis A (10.2%) (fig. 1).

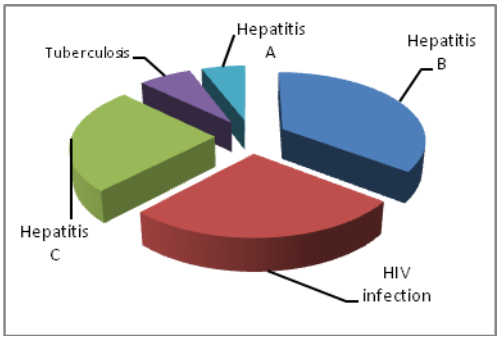

Fig. 1. Diseases considered by the patients as having a high risk of transmission

The subjects with a medium level of education showed a higher concern regarding the HIV infection (87.3%) while the subjects with high education were more worried about the viral hepatitis transmission (77.7%).

The majority of the patients (82.6%) felt to be adequately protected against the spread of infectious diseases. Men (94.6%) showed more confidence in the dental staff than women (72.3%) who manifested an increased anxiety regarding the risk of infection. 13.6% of the subjects are suspicious about their safety and therefore avoid or delay the dental treatment. Older people (79.2%) and those with medium education (70.1%) trust that appropriate measures are applied in order to protect them.

Regarding the protective equipment the patients want the dentist to wear rubber gloves (89.2%), masks (61.5%) and glasses (45.5%) during the dental treatment (fig. 2). 98.2% of the subjects , without significant differences by gender or education level, appreciate that those equipments decrease the risk of infectious diseases transmission.

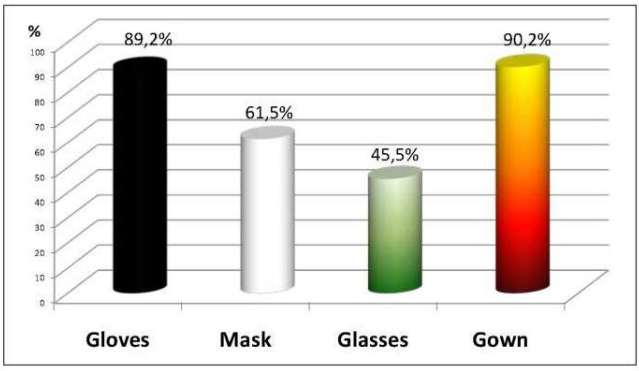

Fig. 2. Patients options regarding the dentist's protective equipment

The patients consider that the main strategies to prevent the spread of the infectious diseases are: hands hygiene (74.2%), disinfection of the surfaces after each patient (52.5%) and the sterilization of the instruments (43.6%).

The desire of the patients to be involved in the infection control procedures differs

by age and gender. Half of them (47.3%) are interested in the application of the procedures like surfaces disinfection, changing the glass for oral rinses, hand cleaning, using of an individual set of instruments, replacement of the dentist protective equipment for each patient. Of those 43.2% patients belonged to the age group of 19-35 years and 37.2% to the age group of 36-64 years.

Female subjects are twice as interested in the follow up of infection control procedures as males (53.4% respectively 25.2%). 10.7% of women and 23.4% of men consider that they do not have the necessary knowledge in this domain and 6.1% of women and 9.1% of men do not want to "offend" the medical staff. 6.2% of female subjects and 12.4 of male subjects are not interested in these issues and protocols (fig. 3).

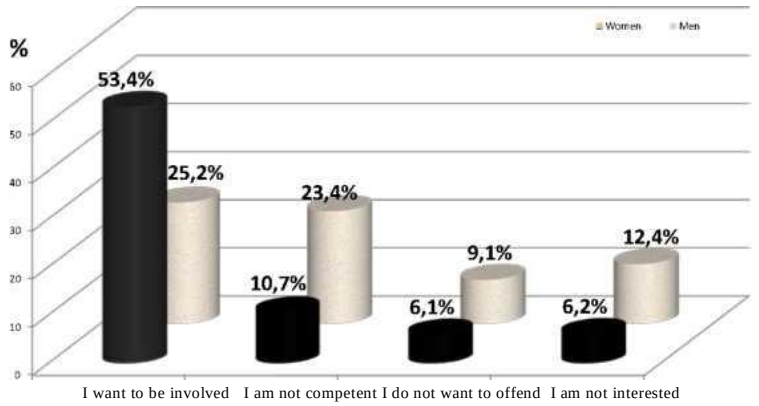

Fig. 3. Patients' involvement in the infection control procedures

DISCUSSION

The evaluation of the patient's perception on infection control procedures is particularly important in motivating the dentists to adopt the specific procedures for safety.

The assessment of the patients' attitude and perspective towards infection control revealed that majority of them trust the medical team and feel protected in the dental office (4). In this study concerns about safety procedures used by dentists are expressed especially by young people while older patients claim that they do not have the required competence to evaluate those aspects. The differences by gender were significant, over one third of men claiming that the infection control procedures are not of their concern. A high level of infection control awareness was seen in the female group of patients.

The study results reveal that the majority of the patients want the dentist to wear protective equipment in order to reduce the risk of infection transmission. Almost 90% of the subjects consider that protective gloves are indispensable, results comparable to those reported by other authors (5). The masks and goggles are also recommended to be worn by the dental team but less important for the patients, findings close to those presented in other studies (6, 7). Patients also expressed firm attitudes regarding the importance of routinely followed infection control procedures like hands hygiene, disinfection of the surfaces

after each patient and the sterilization of the instruments.

The educational level influenced the patients' wiliness to be involved in their own health care. The high level of education resulted in a high patients' implication in their own protection with major benefits on the safety of the dental treatment.

The relative high proportion of patients not willing to be involved in assessing the safety protocols during the dental treatment may be due to the confidence in the medical team but also to the lack of knowledge about the risks of infection and the measures required to reduce it.

CONCLUSIONS

The majority of the patients, especially men, feel protected against infection transmission but they require the medical team to wear protective equipment and adopt the safety protocols. The patients with high level of education desire to be involved in evaluation of the recommended infection control measures considering that an effective communication with the dentist guaranties an increased quality level of the dental treatment.

EVALUATION OF FREE RADICAL SCAVENGING ACTIVITY OF SOME ANTIOXIDANTS (Abstract). Measurement of free radical scavenging capacity of antioxidants is influenced by a number of parameters that depend on reaction rate. **Aim**: A new method for assessing the free radical scavenging activity in which the influence of antioxidant concentration and reaction rate on chlorpromazine radical cation absorbance are simultaneously monitored. **Materials and methods**: The change in radical solution absorbance at 525 nm within a fixed time at different concentrations of the standard antioxidant – ascorbic acid (AA) are determined and percent inhibition is calculated. **Results**: The percent inhibition of color was plotted versus time, and the area under the curve was calculated for each concentration of the standard antioxidant. The calibration curve was obtained by plotting the area under the curve versus ascorbic acid concentration. The antioxidant activity of the samples was calculated using the regression line equation ($r^2 = 0.9991$) and expressed as ascorbic acid molar equivalents (AAE) depending on the unit of measurement chosen for the tested product. **Conclusions:** The proposed method takes into account the two parameters influencing the kinetics of the reaction between antioxidant and radicals, namely the antioxidant concentration and fixed time for measuring absorbance. **Keywords:** FREE RADICAL SCAVENGING, AREA UNDER THE CURVE.

To assess the antioxidant activity, some researchers have proposed a standardized protocol consisting of a series of steps aimed at identifying and quantifying the antioxidant action (1).

An important step in this protocol is the evaluation of free radical scavenging activity of the tested product. Free radical scavenging activity of the antioxidants is based on their ability to donate one hydrogen atom (HAT) or transfer an electron to free radical (ET).

The analytical methods for assessing the free radical scavenging capacity are based either on the detection of stable or unstable free radicals scavenging. Stable free radical chromophores are obtained in advance by a controlled oxidation reaction; their color diminishes following the interaction with the free radical scavenging antioxidant.

The most commonly used free radicals are: the $ABTS^{\bullet+}$ radical cation, obtained by chemical oxidation of 2,2'–azino–bis (3–ethylbenzothiazoline–6–sulfonic acid), which has maximum absorptions on VIS

and IR spectra at 415 nm, 645 nm, 734 nm, and 815 nm, respectively, and DPPH radical (1,1–diphenyl–2 picryl hydrazyl) having an absorption maximum at 516 nm due to the unbound electron on the nitrogen atom. These methods use Trolox, a synthetic, water-soluble vitamin E analogue, as a reference standard antioxidant. The main drawback of these methods is the use of artificial radicals that have not been identified in any biological system (2-5).

In living organisms, oxidation reactions produce short-lived, unstable free radicals as intermediates during oxidation process such as $OH^{\bullet}$ (hydroxyl radical), $R–O–O^{\bullet}$ (peroxyl radical), $O_2^{\bullet-}$ (superoxide radical anion) and NO (nitric oxide) or $ONOO^-$ (peroxynitrite).

The development of in vitro methods for assessing the ability of detecting such radicals includes, first of all, the generation of model-radicals on which the antioxidant to intervene. The literature cites various options for obtaining these short-lived radicals and evaluating the ability of some compounds to quench these radicals (6,7).

This paper proposes an improved method for the evaluation of free radical quenching activity using as chromophore indicator the radical cation obtained by controlled oxidation of chlorpromazine with potassium persulfate ($CP^{\bullet+}$).

Chlorpromazine radical cation is involved in a number of oxidation processes in biological systems and has enough stability to monitor color change under the action of antioxidants. The proposed method combines the influence of two factors involved in the kinetics of free radical quenching reaction: antioxidant concentration and reaction rate. The standard antioxidant is ascorbic acid.

MATERIAL AND METHODS

***Reagents*:**

- Chlorpromazine (Sigma) maleate solution 10^{-2} M;
- Potassium persulphate (Merck) solution 10^{-3} M;
- Hydrochloric acid (Farmitalia) solution 1 M;
- L (+)–scorbic acid (Merck) solution 2.10^{-4} M prepared at the time of use.

***Equipment*:**

- Hewlett Packard 8453 diode-array UV–VIS spectrophotometer;
- Scaltec analytical balance.

Chlorpromazine radical cation is prepared by oxidation of chlorpromazine maleate with potassium persulfate in aqueous solution acidified with hydrochloric acid (8).

Twenty minutes after the initiation of reaction, at a volume of 2 ml pre-formed radical solution 1 ml of standard ascorbic acid solution in different concentrations (10–100 μM/L) is added and then analyzed by VIS spectrophotometry at $\lambda = 525$ nm in a 1 cm cuvette against water. Absorbance of the solutions is determined at 10 minutes and 20 minutes after the addition of ascorbic acid.

Percent inhibition is calculated using the relationship:

$$\% \text{ Inhibition } = \frac{A_r - A_s}{A_r} \cdot 100$$

where A_s – sample absorbance
A_r – radical absorbance

Plot the variation of percent inhibition change during the time interval considered for each concentration value. The area under the curve is calculated. The calibration curve is obtained by plotting the values of the area under the curve against ascorbic acid concentration.

RESULTS AND DISCUSSION

Percent inhibition of radical solution absorbance was calculated at 10 minutes and 20 minutes after the addition of standard ascorbic acid solution and the area under the curve was calculated for each concentration in the studied range (10–100μM / L) (tab. I).

TABLE I

Area under the curve calculated in $CP^{\bullet+}$ – ascorbic acid (AA) system

AA (μM/L)	Absorbance		Inhibition (%)		AUC
	10 min.	20 min.	10 min.	20 min.	
0	0.53103	0.49920	–	–	–

20	0.48185	0.45002	9.261247	9.851763	95.56505
30	0.46253	0.43070	12.89946	13.72196	133.1071
40	0.44335	0.41152	16.51131	17.56401	170.3771
50	0.42005	0.38822	20.89901	22.23157	215.6529
60	0.39976	0.36793	24.71988	26.29607	255.0798
70	0.38394	0.35211	27.69900	29.46514	285.8207
80	0.36262	0.33079	31.71384	33.73598	327.2491
90	0.34415	0.31232	35.19199	37.43590	363.1394
100	0.32653	0.29470	38.51007	40.96554	397.3781

Profile variation of the area under the curve against the concentration of standard antioxidant (ascorbic acid) is shown in figure 1.

By plotting the values of the area under the curve depending on ascorbic acid concentration the calibration curve was obtained (fig. 2).

Regression line was calculated statistically (tab. II).

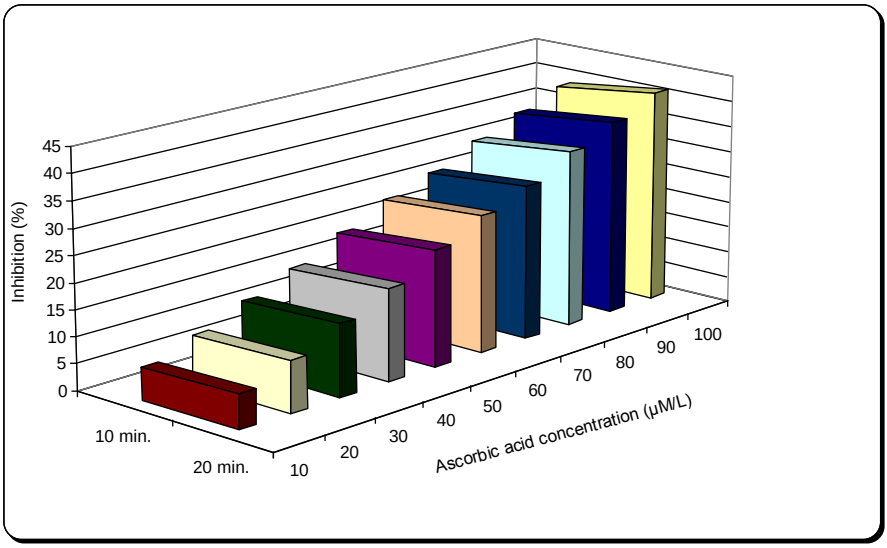

Fig. 1. Profile of area under the curve at different ascorbic acid concentrations

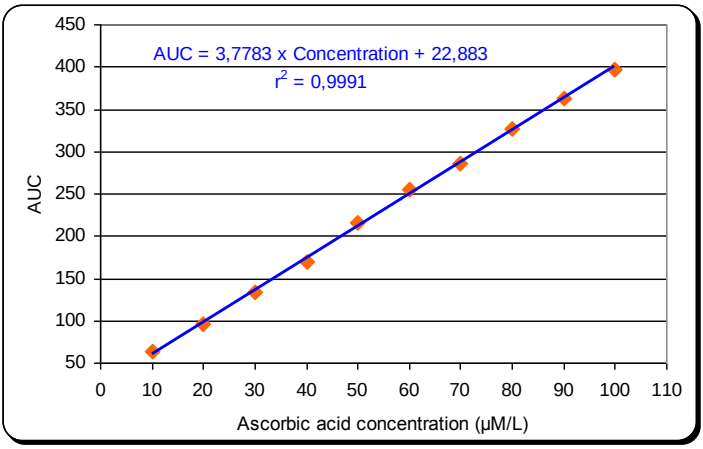

Fig. 2. Area under the curve (AUC) against ascorbic acid concentration

TABLE II

Statistical calculation of regression line

Parameters	AUC)
Equation for the regression line	AUC = 3.7783 x C + 22.883
Regression coefficient (r^2)	0.9991
Intercept	22.883
Slope	3.7783

In order to determine free radical scavenging activity of specific products the absorbance of the sample (obtained by the appropriate processing of the product) and radical cation has to be measured twice (previously fixed time), the same as in the case of the standard. The percent inhibition is calculated and then the area under the curve is determined by plotting the variation of percent inhibition against the fixed time interval. The equation of the calibration curve is used to calculate the antioxidant activity of the samples, expressed as ascorbic acid molar equivalents of (AAE) according to the unit of measurement chosen for the sample.

$$\text{Concentration } (\mu M/L) = \frac{AUC - 22.883}{3.7783}$$

The use of chlorpromazine radical cation in the development of a spectrometric method for determining the free radical scavenging capacity of antioxidants has two advantages. On the one hand, this radical is involved in oxidative processes in living organisms, and, on the other hand it is sufficiently stable that its change in absorbance in the presence of the antioxidant to be monitored with good accuracy.

By the proposed improved method the free radical scavenging activity is determined using a specific parameter for the evaluation of antioxidant activity, namely the area under the curve, as a measure of the contribution to total antioxidant activity of the analyzed products. This parameter combines the influence of variable factors that can alter the accuracy of measurements: fixed time measurement and antiox-

idant concentration.

CONCLUSIONS

We propose a spectrometric method for the evaluation of free radical scavenging activity based on the discoloration reaction of chlorpromazine radical cation chromophore (radical indicator) by ascorbic acid (standard antioxidant). This improved method uses as specific parameter the area under the curve that combines the variable factors influencing the kinetics of the reaction between radicals and antioxidants, namely antioxidant concentration and the time interval during which the determination is made. This parameter is a complete measure of the ability of antioxidants to capture free radicals. The proposed method is simple, requires standard equipment and can be adapted to assess the free radical scavenging activity of various products: herbs, cosmetics, food.

BIOACTIVITY SCREENING OF *PINUS BRUTIA* BARK EXTRACTS: SUPEROXIDE DISMUTASE-LIKE AND NITRIC OXIDE SCAVENGING EFFECTS (Abstract): In the Eastern Mediterranean region the wood of *Pinus brutia* Ten. is used as building material, the bark being the main waste of the wood production processes. A study was designed to explore possible medicinal applications for the bark waste. This paper reports on the superoxide dismutase-like and NO scavenging effects of bark extracts. **Material and methods:** Bark extracts (a raw hydromethanolic extract and its fractions) were initially screened regarding their ability to scavenge DPPH radical. The superoxide dismutase-like and NO scavenging effects were further evaluated. Catechin and quercetin were the positive controls in all antioxidant assays. **Results and discussion:** According to the EC_{50} values, all extracts (11.8 ± 0.1 – 21.10 ± 0.05 μg/ml) efficiently scavenged DPPH radical in comparison to quercetin (3.13 ± 0.05 μg/ml) and catechin (6.36 ± 0.05 μg/ml). The raw extract, diethyl ether and ethyl acetate fractions (449.46 ± 1.75, 115.43 ± 0.25 and 278.3 ± 2.3 μg/ml, respectively) exhibited higher superoxide dismutase-like effects in comparison to catechin (> 645.1 μg/ml). In NO scavenging assay, the raw extract, ethyl acetate and aqueous fractions (160.63 ± 0.85, 162.96 ± 0.52 and 160.23 ± 2.35 μg/ml, respectively) showed a scavenging ability similar to that of quercetin (156.76 ± 5.05 μg/ml) and higher than the one developed by catechin (242.66 ± 7.65 μg/ml). **Conclusions:** As superoxide anion and NO are important mediators in inflammation, our results support a possible use of *Pinus brutia* bark waste to develop nutraceuticals with efficiency in disorders involving oxidative and inflammatory stress.
Keywords: *PINUS BRUTIA* TEN., SUPEROXIDE DISMUTASE, SUPEROXIDE ANION, NITRIC OXIDE.

Both acute and chronic inflammations are characterized by a high reactive oxygen species (ROS) production. Besides pro-inflammatory mediators, leukocytes (neutrophils, macrophages) release ROS to destroy the source of inflammation (1). There are numerous studies supporting the involvement of superoxide anion, nitric oxide and their reaction product, peroxynitrite, in inflammation. Superoxide anion triggers inflammation by several mechanisms: damage of endothelial cells, increase in micro-

vascular permeability, generation of chemotactic factors such as leukotriene B4, infiltration of neutrophils at the site of inflammation *via* up-regulation of adhesion molecules such as ICAM-1 and P-selectin, generation of pro-inflammatory cytokines (TNF-α, IL-1β, IL-6), induction of lipid peroxidation, poly-ADP-ribose polymerase activation. Regarding the latter mechanism, poly-ADP-ribose polymerase mediates inflammation by inducing cellular necrosis and NF-kB-dependent transcription. Many synthetic superoxide dismutase mimetics are tested on their potential to serve as candidates for the development of new anti-inflammatory agents (1, 2). Despite its well-known benefic effects (relaxation of blood vessels, inhibition of vascular smooth muscle cells proliferation and platelet aggregation and adhesion, decrease of expression of pro-inflammatory genes), NO is an important mediator in inflammatory processes. Pro-inflammatory cytokines induce the production of NO *via* inducible nitric oxide synthase (iNOS). NO generates higher nitrogen oxides which are mainly responsible for DNA damage. In addition, NO inhibits catalase, cytochrom P-450, ribonucleotide reductase (enzyme responsible for DNA synthesis) and couples to superoxide generating peroxynitrite. Peroxynitrite is a highly pro-inflammatory and cytotoxic reactive species; it nitrates tyrosine residues in proteins, depletes mitochondrial energy and induces DNA strand breaks (3, 4). In this respect, removal of superoxide or NO are important therapeutic means to reduce the inflammatory processes.

Pinus brutia Ten. (Pinaceae) is widely spread in the Mediterranean region, its wood being used as raw material in furniture industry or as building material. The aim of the present study was to explore possible therapeutic uses for the bark waste. Therefore a raw extract and four fractions were isolated from pine bark. This study investigated the DPPH, superoxide and NO scavenging effects of the raw extract and its fractions.

MATERIAL AND METHODS

Plant material. *P. brutia* bark was supplied by the Cyprus Department of Forests of the Ministry of Agriculture, Natural Resources and Environment in March 2008. Dried bark powder was extracted with 80% methanol (v/v). A crude extract (PbE) and four extractive fractions, namely diethyl ether (PbE1), ethyl acetate (PbE2), n-butanol (PbE3) and aqueous (PbE4) fractions, were obtained according to a procedure described previously (Elena Cretu, submitted).

DPPH radical scavenging assay. The ability to scavenge free radicals was assessed by the DPPH assay (5). Briefly, a DPPH solution was prepared by dissolving 4 mg of DPPH in 100 ml of methanol; the solution was further diluted with methanol to an absorbance of 1.00 ± 0.05 at 517 nm. Different concentrations of *P. brutia* extracts (50 µL) were mixed with DPPH solution (2.95 ml). The mixture was vortexed vigorously and the decay in absorbance at 517 nm was measured after 5 min reaction time. Catechin and quercetin were used as positive controls. The ability to scavenge the DPPH radical was calculated using the following formula: DPPH scavenging activity (%) = $100 \times (A_{start} - A_{end}) / (A_{start})$; A_{start} is the absorbance before adding the test sample and A_{end} is the absorbance after 5 min reaction time.

Superoxide dismutase-like activity assay. The superoxide dismutase-like (SOD-like) activity was evaluated using pyrogal-

lol system for the generation of superoxide anion radical (6). The reaction mixture consisted of 0.05 M Tris-HCl buffer (pH 8.0) containing 1 mM EDTA (2.8 ml), 6 mM pyrogallol (0.2 ml) and samples to be tested (0.1 ml). The absorbance of the mixture at 325 nm was measured every 30 s for 4 min. The dependence of absorbance on time was plotted for every sample (extract, positive control). Catechin and quercetin were the positive controls. The superoxide dismutase-like activity, expressed as superoxide anion radical scavenging activity, was calculated using the equation: SOD-like activity (%) = 100 × (1 – $slope_{sample}/slope_{control}$); $slope_{sample}$ and $slope_{control}$ are the slopes of the curves expressing the dependence absorbance *vs.* time for samples (*P. brutia* extracts, quercetin, catechin) and control, respectively.

Nitric oxide scavenging assay. In this assay, NO is generated by the spontaneous decomposition of sodium nitroprusside in an aqueous solution. The assay was performed according to a previously reported method with minor changes (7). Different concentrations of samples (*P. brutia* extracts, positive controls) (0.5 ml) were mixed with 10 mM sodium nitroprusside (0.5 ml) and phosphate saline buffer (0.5 ml). The mixture was incubated at 30ºC in dark. After 180 min 1% sulfanilamide in 5% phosphoric acid (0.5 ml) was added. The solution was left at 30ºC for 10 min followed by the addition of 0.1% naphtylethylenediamine dihydrochloride. The absorbance of the resulting chromophore was measured at 546 nm. Catechin and quercetin were used as positive controls. The ability to scavenge nitric-oxide was calculated using the formula: NO scavenging activity (%) = 100 × ($A_{control} – A_{sample}$)/$A_{control}$; $A_{control}$ is the absorbance of control and A_{sample} is the absorbance in presence of samples (*P. brutia* extracts, positive controls).

Statistical analysis. All assays were carried out in triplicate. The results were expressed as means ± SD. The EC_{50} values were calculated by linear interpolation between values above and below 50% activity.

RESULTS AND DISCUSSION

DPPH radical scavenging assay. This assay is widely used to screen the free radical scavenging ability of antioxidants. DPPH radical is a stable free radical showing a strong absorbance at 517 nm. Antioxidants scavenge DPPH radical by either hydrogen donation or electron transfer with a consequent decrease in absorbance at 517 nm (8). All *P. brutia* extracts scavenged DPPH radical in a concentration dependent manner. At 5.20 μg/ml the scavenging activity ranged from 17.44 ± 0.22% to 25.95 ± 0.04% while at 83.33 μg/ml all extracts showed scavenging effects higher than 80%. Within this assay, quercetin was more active than catechin (75.12 ± 0.51 *vs.* 41.39 ± 0.42% at 5.20 μg/ml; 96.98 ± 0.57 *vs.* 95.14 ± 0.55% at 83.33 μg/ml). According to the EC_{50} values, the DPPH radical scavenging activity decreased in the following order: quercetin > catechin > PbE2 > PbE3 > PbE > PbE4 > PbE1 (tab. I).

Superoxide dismutase-like activity assay. Within this assay, only PbE, PbE1 and PbE2 scavenged superoxide anion radical dose-dependently thus exhibiting SOD-like activity. As compared by the EC_{50} values, the most active was PbE1 (115.43 ± 0.25 μg/ml) followed by PbE2 (278.3 ± 2.3 μg/ml) and PbE (449.46 ± 1.75 μg/ml). PbE3 and PbE4 showed no activity in this assay. In the same experimental conditions,

catechin had weaker scavenging effects than *P. brutia* extracts. At 645.1 µg/ml, catechin showed only 20.41 ± 0.24% scavenging activity while PbE, PbE1 and PbE2 scavenged superoxide anion radical by 84.16 ± 0.62, 94.80 ± 0.66 and 91.38 ± 0.87%, respectively (tab. II). The scavenging activity of quercetin could not be evaluated due to its low solubility in the reaction medium.

Nitric oxide scavenging assay. NO, generated by the decomposition of sodium nitroprusside, interacts with oxygen generating nitrite and nitrate ions which can be spectrophotometrically quantified by Griess reaction. In the presence of NO scavengers, the production of nitrite ions is significantly reduced (7). The NO scavenging effects of *P. brutia* extracts were concentration dependent. PbE, PbE2 and PbE4 exhibited similar scavenging effects (EC_{50} = 160.63 ± 0.85, 162.96 ± 2.65 and 160.23 ± 2.35 µg/ml, respectively). The scavenging activity of PbE3 was significantly lower (EC_{50} = 219.26 ± 5.00 µg/ml). In case of PbE2, the scavenging activity could not be determined due to the low solubility of its constituents in the reaction medium. It is worthy to note that, according to the EC_{50} values, the scavenging effects of PbE, PbE2 and PbE4 were similar to that of quercetin (156.76 ± 5.05 µg/ml) but higher than the effect showed by catechin (242.66 ± 7.65 µg/ml). The NO scavenging effects decreased as follows: quercetin > PbE4 > PbE > PbE2 > PbE3 > catechin (tab. III).

CONCLUSIONS

This study shows that several extracts isolated from *Pinus brutia* bark have high SOD-like and NO scavenging effects when compared to well known antioxidants such as catechin and quercetin. Both the raw extract (PbE) and two extractive fractions (PbE1, PbE2) exhibited significantly higher SOD mimic effects in comparison to catechin. Fractions PbE2 and PbE4, but also PbE showed NO scavenging potential similar to that of quercetin and higher than the one developed by catechin. These results support a possible use of *Pinus brutia* bark waste to develop nutraceuticals with efficiency in disorders involving oxidative and inflammatory stress. As our previous studies revealed high polyphenolic contents in all extracts, it is possible that, besides other phytochemicals, certain polyphenols mediate SOD-like and NO scavenging effects. Further *in vivo* studies are needed to a better assessment of the potential therapeutic uses of *Pinus brutia* bark extracts.

15-LIPOXYGENASE INHIBITION, SUPEROXIDE AND HYDROXYL RADICALS SCAVENGING ACTIVITIES OF *CEDRUS BREVIFOLIA* BARK EXTRACTS (Abstract): *Cedrus brevifolia* (Hook. f.) Henry, a species endemic to Cyprus, has not been studied regarding its constituents and potential biological activities. **Material and methods:** A crude extract from *Cedrus brevifolia* bark and its four fractions (diethyl ether, ethyl acetate, n-butanol and aqueous fractions) were investigated regarding their capacity to inhibit 15-lipoxygenase and scavenge reactive oxygen species (superoxide anion and hydroxyl radicals). Catechin was used as positive control in all antioxidant assays. **Results and discussion:** In the superoxide anion radical scavenging assay, the crude extract showed the highest activity (EC_{50} = 57.73±1.25 µg/mL) comparable to that of the positive control, catechin (EC_{50} = 52.60±1.65 µg/mL). All other fractions exhibited noticeable scavenging effects against superoxide radical, their EC_{50} values ranging from 76.33±3.50 to 91.06±4.45 µg/mL. The ethyl acetate and n-butanol fractions were the most active in the hydroxyl radical scavenging (EC_{50} = 580.20±18.72 and 792.10±15.36 µg/mL, respectively) and 15-lipoxygenase inhibition assays (EC_{50} = 34.0±0.9 and 40.96±0.45 µg/mL, respectively). **Conclusions:** *Cedrus brevifolia* bark is a valuable source of compounds with reactive oxygen species and 15-lipoxygenase inhibitory activities. These results support further studies for the identification and isolation of the bioactive constituents. **Keywords:** *CEDRUS BREVIFOLIA*, 15-LIPOXYGENASE, SUPEROXIDE ANION RADICAL, HYDROXYL RADICAL

In living cells, reactive oxygen species (ROS) (superoxide anion, hydroxyl, peroxyl and alkoxyl radicals, hydrogen peroxide, singlet oxygen, hypochlorous acid) are produced during normal activities such as mitochondrial respiration, peroxisomal beta-oxidation, cytochrome P450 metabolism. Pathological processes such as inflammation, exposure to ultraviolet and gamma-irradiation are additional sources of ROS (1). In low levels, ROS have important physiological roles (defence against pathogens, cellular signaling) while in high concentrations they become harmful as they damage cells constituents such as lipids, proteins, carbohydrates, DNA (oxidative stress). Oxidative stress plays a key role in the development of cancer, cardiovascular, neurodegenerative and rheumatic diseases, diabetes mellitus (2, 3). One of

the most important factors associated with carcinogenesis is DNA damage produced by ROS. During cell division, these oxidative lesions lead to mutations of the genes that regulate cell growth and differentiation. Lipid peroxidation indirectly induces DNA mutagenic lesions. Final products of lipid peroxidation (epoxides, aldehydes) diffuse from the site of production and bind covalently to DNA, leading to exocyclic adducts with mutagenic potential. The overexpression of NOX enzymes (NADPH oxidases that transfer electrons across membranes generating superoxide anion radical and other ROS) is implicated in ischaemia/reperfusion injury, hypertension and neurodegeneration but also in age-associated hearing loss, cataract and retinal degeneration (1-3). In rheumatoid arthritis, ROS damage the cartilage, extracellular colagen and DNA (4). In diabetes mellitus, the increased production of superoxide anion radical activates polyol and hexosamine pathways, increases the production of advanced glycation end products (AGEs) and the expression of their receptors thus leading to diabetes complications (atherosclerosis, cardiomyopathy) (5). Antioxidants are able to delay or prevent diseases associated with oxidative stress (2, 3). Therefore, there is an increasing interest in finding new antioxidants, especially from natural sources.

Cedrus brevifolia (Hook. f.) Henry (Cyprus cedar) is a conifer belonging to: division-*Pinophyta*, class-*Pinopsida*, order-*Pinales*, family-*Pinaceae*, genus-*Cedrus*. The present natural geographic distribution of *Cedrus* species is limited to the Himalayan Mountains (1500-3200 m) and the Mediterranean coast (1000-2200 m) (6). Few studies on *C. brevifolia* reported an increased sensitivity and a limited growth rate in drought conditions in comparison with other species of cedar (*C. libani*, *C. atlantica*) (7, 8). A genetic diversity study using AFLP (*Amplified Fragment Length Polymorfism*) fingerprinting technique was performed on 17 populations of cedar. For *C. brevifolia*, found in small and fragmented populations, one of the highest levels of intrapopulational diversity was noticed. This unexpected pattern of diversity and differentiation suggests a population in evolution rather than one in decline (9).

The present study was designed to evaluate the antioxidant potential (15-lipoxygenase inhibition, superoxide and hydroxyl radicals scavenging activities) of *C. brevifolia* bark extracts.

MATERIAL AND METHODS

Chemicals. (+) Catechin hydrate, nitrobluetetrazolium (NBT), phenazine methosulphate (PMS), iron (II) sulfate heptahydrate, linoleic acid, lipoxidase from soybean (15-LO), hydrogen peroxide solution were obtained from Fluka (Steinheim, Germany). Sodium salicylate and dimethyl sulfoxide (DMSO) were purchased from Sigma-Aldrich (Steinheim, Germany). Tris (hydroxymethyl)aminomethane (Tris) and beta-nicotinamide adenine dinucleotide reduced (NADH) were supplied by Merck (Darmstadt, Germany). All other solvents and reagents were of analytical grade.

Equipments. For UV/VIS measurements, a Jasco V-550 spectrophotometer was employed.

Plant material.C. brevifolia bark was supplied by the Cyprus Department of Forests of the Ministry of Agriculture, Natural Resources and Environment in March 2008.

Preparation of bark extracts. Dried and powdered bark was extracted with 80%

methanol (v/v); the crude extract (CbE) was further fractionated by successive liquid-liquid partition. The diethyl ether (CbE1), ethyl acetate (CbE2), n-butanol (CbE3) and aqueous (CbE4) fractions were obtained according to a methodology described previously (Elena Crețu, submitted). The polyphenolic content and profile of *C. brevifolia* bark extracts were studied and reported (Elena Crețu, submitted).

15-Lipoxygenase inhibition assay. Extracts and catechin (positive control) were dissolved in DMSO in concentrations ranging from 0.31 to 5 mg/mL. The reaction mixture consisted of extracts/catechin and 0.2 M borate buffer (pH 9.0) containing 15-LO (10000 U/mL). After 10 min incubation at 25°C, the substrate (linoleic acid in borate buffer) was added. Absorbance of the reaction mixture was measured at $\lambda = 234$ nm after 30 and 90 s reaction time. Percent 15-LO inhibition was calculated using the formula:

Inhibition of 15-LO (%) = $100 \times [(A_{control,\ 90} - A_{control,\ 30}) - (A_{sample,\ 90} - A_{sample,\ 30})/(A_{control,\ 90} - A_{control,\ 30})]$, where $A_{control,\ 30}$ and $A_{control,\ 90}$ are the absorbances of the control after 30 and 90 s reaction time, respectively. $A_{sample,\ 30}$ and $A_{sample,\ 90}$ are the absorbances of the mixtures containing extracts/catechin after 30 and 90 s reaction time, respectively (10). The assay was carried out in triplicate and the results were expressed as mean values ± SD.

Superoxide anion radical scavenging assay. Extracts and catechin (positive control) were dissolved in DMSO in a concentration range of 0.039 − 1.25 mg/mL. The reaction mixture consisted of extracts/catechin and 16 mM Tris-HCl buffer (pH 8.0) containing 557 μM NADH, 45 μM PMS and 108 μM NBT. Absorbance of the reaction mixture was measured at $\lambda = 560$ nm after 5 min incubaton at 25°C. Percent superoxide anion radical scavenging activity was calculated as follows:

Superoxide anion radical scavenging activity (%) = $100 \times (A_{control} - A_{sample})/A_{control}$, where $A_{control}$ is the absorbance of control and A_{sample} is the absorbance in presence of extracts/catechin (11). The assay was carried out in triplicate and the results were expressed as mean values ± SD.

Hydroxyl radical scavenging assay. Extracts and catechin (positive control) were dissolved in DMSO in different concentrations ranging from 4 to 12 mg/mL. The final reaction mixture contained extracts/catechin, 1.5 mM iron (II) sulfate heptahydrate, 20 mM sodium salicylate and 6 mM hydrogen peroxide. The mixture was incubated at 37°C for 30 min. After cooling, the absorbance was measured at $\lambda = 562$ nm. Percent hydroxyl radical scavenging activity was calculated using the formula:

Hydroxyl radical scavenging activity (%) = $100 \times (A_{control} - A_{sample})/A_{control}$, where $A_{control}$ is the absorbance of control and A_{sample} is the absorbance in presence of extracts/catechin (12). The assay was performed in triplicate and the results were expressed as mean values ± SD.

RESULTS AND DISCUSSION

15-Lipoxygenase inhibition assay. 15-LO plays a major role in the development of atherosclerosis. The enzyme oxidizes circulating low-density lipoproteins (LDL) initiating the formation of the atherosclerotic plaques in the arterial wall. 15-LO is also responsible for other processes involved in atherogenesis such as endothelial injury, proinflammatory cytokine release and cytolysis by modulating numerous cellular signaling pathways (13). In this

assay, all extracts inhibited 15-LO in a concentration-dependent manner. At the highest concentration tested (5 mg/mL), CbE3 (97.16±0.34%) and CbE2 (97.08±0.76%) were more active than the positive control, catechin (88.30±1.48%) (fig. 1). The EC_{50} values confirmed that CbE2 (34.0±0.9 µg/mL) and CbE3 (40.96±0.45 µg/mL) were the most active among *C. brevifolia* extracts but slightly less active than catechin (29.43±0.55 µg/mL) (tab. I).

Antioxidant activities of *Cedrus brevifolia* bark extracts

Extract/ Positive control	EC_{50}(µg/mL)		
	15-LO inhibition assay	Superoxid anion radical scavenging assay	Hydroxyl radical scavenging assay
CbE	63.6 ± 0.6	57.73 ± 1.25	822.9 ± 13.9
CbE1	> 83.33	84.93 ± 1.35	> 1125
CbE2	34.0 ± 0.9	76.33 ± 3.50	580.20 ± 18.72
CbE3	40.96 ± 0.45	87.20 ± 1.95	792.10 ± 15.36
CbE4	> 83.33	91.06 ± 4.45	> 1125
Catechin	29.43 ± 0.55	52.60 ± 1.65	318.40 ± 4.45

Superoxide anion radical scavenging assay. Superoxide anion radical is generated *in vivo* during mithocondrial respiration; it is also produced by phagocytic cells to kill pathogens. Superoxide radical plays important roles in many physiological processes such as gene transcription, cell growth and proliferation, apoptosis. Despite its beneficial effects, superoxide radical gives rise to more harmful ROS. It can react with nitric oxide to form peroxynitrite anion, a highly cytotoxic species. In addition, it reacts with hydrogen peroxideyielding hydroxyl radical (Haber-Weiss reaction); the latter is very deleterious for all biomolecules in or near its generation site. Superoxide radical-induced oxidative stress is involved in the development of many pathological conditions and diseases (inflammation, cardiovascular and neurodegenerative disorders, cancer, ageing) (14-18). As shown in fig. 2, the superoxide radical scavenging activities of *C. brevifolia* bark extracts were concentration-

dependent. At 1.25 mg/mL, CbE was the most active showing 81.21±0.38% scavenging activity, followed by CbE2 (77.25±0.83%), CbE1 (74.63±0.77%), CbE3 (64.74±1.58%) and CbE4 (59.68±1.02%); at the same concentration, catechin showed 72.81±0.76% scavenging activity. According to the EC_{50} values, CbE(57.73±1.25 µg/mL) was the most active, its scavenging effect being comparable to that of catechin (52.60±1.65 µg/mL) (tab. I).

Hydroxyl radical scavenging assay. Hydroxyl radical is generated *in vivo* by the transition metal-induced reduction of hydrogen peroxide (Fenton reaction). It is considered to be the most aggressive ROS leading to oxidative damage of polyunsaturated fatty acids, polypeptide chains and DNA bases. It is worthy to note that hydroxyl radical is responsible for lipid peroxidation, a process that alters both the structure and functions of the cell membranes causing cell damage. Besides, hydroxyl radical is known to be involved in quinone toxicity, radiation injury, ischemia-reperfusion injury, diabetes, cancer and ageing. (17-20). At 12 mg/mL the hydroxyl radical scavenging activity of CbE reached 66.39±0.52%. Similar activities were recorded for CbE2 (64.81±0.36%) and CbE3 (65.34±0.24%) while CbE1showedonly 22.57±1.03% activity (fig. 3). With regard to the EC_{50} values, CbE2 (580.20±18.72 µg/mL) was the most active hydroxyl radical scavenger; its activity was 1.8 times lower than that of catechin (318.40±4.45 µg/mL) (tab. I).

CONCLUSIONS

The results of this study show that *C. brevifolia* bark is an important source of compounds with 15-LO inhibitory and reactive oxygen species scavenging effects. The fractionation of the crude extract (CbE) led to fractions with higher activity in 15-LO inhibition and hydroxyl radical scavenging assays. The ethyl acetate (CbE2) and n-butanol (CbE3) fractions showed remarkable 15-LO inhibitory activity in comparison with catechin. In addition, CbE2 and CbE3 were highly active as hydroxyl radical scavengers. The fractionation did not increase the scavenging ability towards the superoxide anion radical as CbE was the most active among the bark extracts. However, it is worthy to note that all fractions showed high scavenging effects towards the superoxide anion radical. All these findings confirm the potential therapeutic value of *C. brevifolia* bark and support further studies for the identification and isolation of the bioactive constituents.

TRIPLEX REAL-TIME PCR FOR DETECTION OF METHICILLIN-RESISTANT *STAPHYLOCOCCUS AUREUS* AND PANTON-VALENTINE LEUKOCIDIN IN NORTH-EAST ROMANIA (Abstract): The aim of the present study was to investigate *S. aureus* isolates for the presence of methicillin-resistance and Panton-Valentine leukocidin (PVL) genes and to further characterize positive strains by means of antibiotic resistance patterns. **Material and Methods**: We used a triplex Real-Time PCR method for simultaneous detection of *nuc*, *mec*A and *pvl* genes in clinical isolates from 188 patients admitted to "Sf. Parascheva" Infectious Diseases Hospital Iaşi, during a 3 year period (2008-2010). **Results** The study revealed a relatively high rate of PVL-producing strains (23.93%), mainly community-associated (CA-MRSA) (51.11%). Most *pvl*-positive CA-MRSA isolates were resistant to erythromycin (91.3%), but none was resistant to clindamycin, fluoroquinolones, rifampicin, chloramphenicol or fusidic acid. **Conclusions:** Antibiotic susceptibility testing showed a high rate of multidug-resistance among strains classified as CA-MRSA (54.83%), but not among PVL-producers (4.44%). Although resistance to fusidic acid was previously proposed as a marker for PVL-producing CA-MRSA, our data suggest that we cannot rely on resistance to fusidic acid to screen for PVL-producing CA-MRSA in our setting. **Keywords**: MRSA, MECA, PVL.

Staphylocccus aureus is an important hospital and community-acquired pathogen that causes a broad spectrum of diseases, for which the currently available treatments are at risk of becoming less effective, as this bacterium is able to rapidly acquire resistance to antibiotics. The mobile element SCC*mec* carries *mec*A gene encoding a low-affinity PBP2a that confers resistance to beta-lactam antibiotics (1). Methicillin-resistant *S. aureus* (MRSA) is a common agent of nosocomial infections (HA-MRSA) and is now increasingly implicated in infections among persons in the community without established risk factors for MRSA acquisition (CA-MRSA) (2). *S. aureus* pathogenicity is related to a wide variety of virulence factors that allow it to colonize, invade and evade the immune system. These factors include Panton-Valentine leukocidin (PVL), a pore-forming cytotoxin, encoded by *lukF-PV* and *lukS-PV* genes. The toxin targets polymorphonuclears and contributes to tissue necrosis. Infec-

tions caused by PVL-producing strains are characterized by an increased systemic inflammatory response, decreased survival in patients with community pneumonia and increased severity of localized lesions (3). PVL has been linked to skin and soft tissue infections (SSTIs), necrotizing pneumonia, bone and joint infections and was associated with CA-MRSA infections that affect young healthy individuals with no exposure to healthcare centers (4).

Our aim was to evaluate the prevalence of PVL-producing MRSA strains in "Sf. Parascheva" Infectious Diseases Hospital Iaşi, using a triplex RT-PCR technique that allows rapid and simultaneous detection of *nuc*, *pvl* and *mec*A genes. This study constitutes a preamble to the use of multiplex RT-PCR directly on clinical specimens. We also analyzed the phenotypic antimicrobial resistance profiles among CA-MRSA, HA-MRSA and methicillin-susceptible *S. aureus* (MSSA). Multi-drug resistance (MDR) among MRSA was defined as concurrent resistance to three or more non-beta-lactam antimicrobial agents.

MATERIAL AND METHODS

Clinical isolates. In total, 188 non-duplicate *S. aureus* isolates from "Sf. Parascheva" Infectious Diseases Hospital Iaşi were evaluated in the present study. The strains were isolated from pus (102 strains), blood-cultures (BC) (46 strains), cerebrospinal fluid (CSF) (6 strains), sputum (18 strains) or from multiple specimens (16 strains), from 2008 to 2010.

Triplex Real Time PCR. The isolates were analyzed for the presence of *mec*A, *pvl* and *nuc* genes using a triplex RT-PCR method previously described (5). Nucleic acid was extracted using *GenElute Bacterial Genomic DNA kit* (Sigma Aldrich, Germany). Primers and probes were synthesized based on oligonucleotide sequences previously described by McDonald *et al.*(6), and were used in concentrations of: 0.30 μM *mec*A primers, 0.1 μM *mec*A probes, 0.40 μM *pvl* primers, 0.1 μM *pvl* probes, 0.05 μM *nuc* primers, 0.05 μM *nuc* probes. Reactions were performed with *Brilliant Multiplex QPCR Master Mix* (Agilent Technologies, USA) under the following thermal cycling conditions: 10 min at 95°C, followed by 40 cycles of 95°C for 15 s and 55°C for 1 min. Simultaneous amplification of target genes was detected with Stratagene MX3005P system (Agilent Technologies, USA). *S. aureus* ATCC 25923, 33592 and 49775 were used as controls of amplification.

Antibiotic susceptibility testing. Antimicrobial susceptibility patterns were evaluated using ATB STAPH 5 strips (bioMérieux, France) and disk diffusion method, as recommended by CLSI guidelines 2008-2010. We tested the sensitivity to the following antibiotics: penicillin (P), oxacillin (OX), cephoxitin (FOX), clindamycin (CM), erythromycin (E), tetracycline (TE), gentamicin (G), rifampicin (RIF), trimethoprim/sulfamethoxazole (SXT), fluoroquinolones (FQ), chloramphenicol (C), linezolid (LZD), teicoplanin (TEC) and fusidic acid (FUS). Inducible resistance to CM was assessed by double-disk (E and CM) diffusion method (D-zone test). Minimum inhibitory concentrations (MICs) for vancomycin (VA) and OX were determined using E-test method (bioMérieux, France).

RESULTS

We detected *mec*A gene in 86 isolates (45.74%), while phenotypic testing failed to detect methicillin-resistance in 5 cases.

Thus, the sensitivity of 1 µg oxacillin disk testing was 95.34% and the sensitivities of 30 µg cephoxitin disk testing and ATB STAPH 5 strips were 97.67%, compared to *mec*A detection as gold standard. MICs for OX varied between 0.094-256 µg/ml, with a heteroresistance rate of 21.27% of the total number of strains. Of the total number of tested strains, 45 were *pvl*-positive (23.93%), representing 33.72% of MRSA isolates. Most *pvl*-positive strains were isolated from pus (82.22%), the rest being isolated from BC (6), CSF + BC (1) and CSF + BC + sputum (1). Clinical evolution for those patients was as follows: death (2 cases), aggravated (1), unchanged (6), improved (26) and healed (10). Out of all *pvl*-positive strains, 16 were MSSA, with 6 different resistance patterns, the most common being resistance to P (8 strains); one strain was susceptible to all antibiotics (tab. I).

TABLE I
Antibiotic resistance patterns for MSSA *pvl*-positive strains

Resistant strains	P	G	CM	E	TE
8	+				
3	+	+			
1	+			+	
1	+		+		
1	+				+
1	+	+		+	+

Among PVL-producing MRSA (29 strains), 7 resistance profiles were described, the most common being single-drug resistance to E (22 strains); of those strains, two were MDR (tab. II). None of the *pvl*-positive strains showed inducible CM resistance and all of them were susceptible to C, LZD, TEC, VA and FUS. Among PVL-non producing strains,44 different resistance profiles were detected, most of them being MSSA resistant to P (27.97%) and MRSA multidrug-resistant to E, CM and TE (11.18%).

TABLE II
Antibiotic resistance patterns for MRSA *pvl*-positive strains

Resistant strains	G	CM	E	TE	FQ	SXT	RIF
22			+

1	+						
1	+						+
1				+	+		
1		+	+	+			
1	+		+	+		+	

Community-onset infections were defined as those episodes with a positive culture within 48h of admission, without health care-associated risk factors (history of hospitalization in the past year, surgery, renal dialysis, residence in a long-term care facility, presence of percutaneous medical devices or positive MRSA culture within the preceding 1 year). Based on this definition, 32.97% of the total number of isolates and 72.09% of MRSA strains were considered CA-MRSA; out of those, 37.09% were PVL-producing strains. A comparison of antibiotic resistance between CA-MRSA and HA-MRSA strains reveals a higher resistance rate for TE, G, RIF and FQ in the case of HA-MRSA isolates, while resistance rates to SXT, C and FUS were similar (fig. 1).

Out of 86 MRSA strains, 54 were MDR, the majority being classified as CA-MRSA (34/54), with the most frequent resistance profile: E, CM and TE (10 strains). Most

MDR strains classified as HA-MRSA were additionally resistant to G, RIF and FQ (9 strains). Only 2 *pvl*-positive strains were MDR, representing 3.7% of MDR strains.

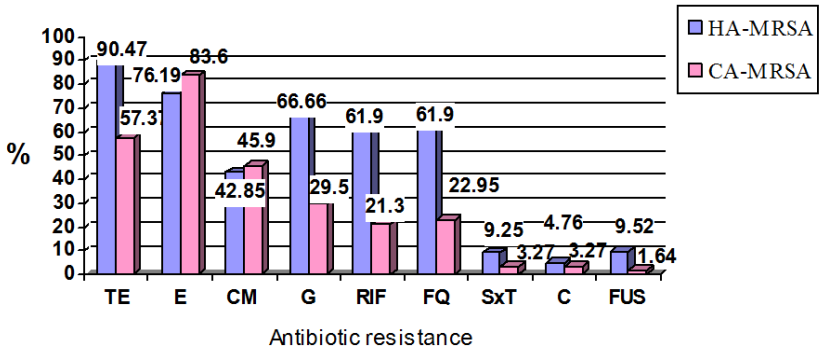

Fig. 1. Antibiotic resistance of CA-MRSA *versus* HA-MRSA strains

DISCUSSION

MRSA rate determined by this study (45.74%) is concordant with previously published data by Dorneanu *et al* (47%)(7) and with reports from EARS-Net, placing Romania on one of the first places on the incidence of invasive MRSA infections (39.1%)(8). Correct identification of methicillin-resistance is needed for effective monitoring of MRSA spread. Since conventional methods of antibiotic susceptibility testing sometimes fail to detect hetero-resistant strains, molecular techniques were developed as standard tests for MRSA confirmation. These techniques are not accessible for routine testing in clinical laboratories, so evaluation of sensitivities for most frequently used phenotypic methods is imposed. Our data regarding MRSA detection were similar to those reported by Anand *et al*. (9) and Pottumarthya *et al*. (10), showing a sensitivity of 30 µg cephoxitin disk testing of 100% and 99.0% respectively, while a weaker concordance was observed when 1 µg oxacillin disk was used (sensitivity 87.5% and 94.7% respectively).

The emergence and community dissemination of new and virulent MRSA strains harboring PVL constitutes a public health concern (11, 12). Some authors anticipate the replacement of HA-MRSA strains by community strains infiltrating the hospital environment due to their colonization properties (13). The majority of CA-MRSA causes SSTIs, but certain cases can progress to invasive tissue infections and bacteremia (14). Usually, these strains are sensitive to most non-beta-lactam antibiotics and have a low level of methicillin-resistance, often expressed heterogeneously. Our study found an oxacillin heteroresistance rate in CA-MRSA of 45.16% and a prevalence of MDR among these strains of 54.83%, with resistance to: TE (94.11% of MDR strains), E (91.17%), CM (79.41%), G (44.11%), FQ (41.17%), RIF (38.23%), SXT (5.88%), C (5.88%), FUS (5.88%). These data are concordant with observations that indicate a blurring of the boundaries between community and hospital, with CA-MRSA becoming more resistant to antibiotics (15).

The role of PVL toxin to the virulence of *S. aureus* has been disputed due to inconclusive results of *in vivo* studies using mice. But epidemiological data and studies on rabbit model, whose neutrophils are as

sensitive to PVL action as human cells, are linking necrotizing skin infections with PVL-production (16). More than 250 articles published during 2002-2007 identified an association between PVL and CA-MRSA disease outbreaks (17). Hedin *et al*. (18) showed that PVL is a stable genetic marker for CA-MRSA infections, 96% of *pvl*-positive strains being CA-MRSA, while 81% of *pvl*-negative strains were HA-MRSA. Fang *et al.*(19) reported that 56 % of 104 CA-MRSA strains carried *pvl* genes and a similar rate (66%) was detected by Berglund *et al*.(20). Our study showed a relative high rate of *pvl*-positive isolates (23.93%), when compared to the results of Holms *et al.* (21) that noted a low rate of PVL-producers among *S. aureus* isolates (1.6%).

Most of *pvl*-positive strains analyzed were CA-MRSA (23 / 45, 51.11% respectively). Only two PVL-producing CA-MRSA strains were MDR, showing resistance to E, G, TE, one strain being also resistant to SXT. Most *pvl*-positive CA-MRSA isolates (21/23) were resistant to E, but none was resistant to CM, FQ, RIF, C or FUS. The 100% sensitivity to FUS among those strains is discordant with reports suggesting that fusidic acid resistance can be used for identification of PVL-producing CA-MRSA (22). In our study none of the PVL-producing strains showed resistance to FUS.

CONCLUSIONS

Multiplex RT-PCR is a useful tool for rapid detection of MRSA and identification of genes encoding the synthesis of virulence factors. The introduction of this technique in our laboratory allowed us to verify the results of phenotypic testing, which showed good sensitivity in the detection of MRSA (95.34 – 97.67%). Detection of *pvl* genes revealed a relatively high rate of PVL-producing strains (23.93%) that were associated mostly with CA-MRSA strains and a particular antibiotic resistance profile with resistance to E and sensitivity to CM, FQ, RIF, C and FUS. According to our data, resistance to fusidic acid, although previously proposed as a marker for PVL-producing CA-MRSA, cannot be used to screen for those strains in our setting. Antimicrobial susceptibility testing showed a high rate of MDR among CA-MRSA (54.83%), but not among PVL-producers. This raises the problem concerning the tendency of community strains to spread into hospitals and gain resistance.

DIVALENT CATIONS LEVELS CHANGES IN NEPHROTIC SYNDROME

DIVALENT CATIONS LEVELS CHANGES IN NEPHROTIC SYNDROME (Abstract): Divalent cations (calcium, magnesium, zinc, cooper, manganese) play an important role in various biological processes. Different acute or chronic renal disorders in children or adults modify the urinary excretion of these cations and may influence their concentrations in organism. **Aim:** Evaluation of the changes of some divalent cations levels (Cu, Zn, Mg, Ca) in acute renal diseases. **Material and methods:** We measured plasma concentrations and urinary excretion of cations in pediatric patients with acute urinary infections. We also evaluated malondyaldehide (MDA) and total antioxidant capacity (TAC) plasma levels. **Results:** The obtained results show that serum levels of Ca, Cu, Zn are decreased in patients with acute urinary infections compared with a control group of healthy children, while urinary excretion of Cu and Zn there were higher in group study compared with control group. There are no significant differences of the serum magnesium concentration. Increased plasma MDA levels and decreased plasma TAC, Cu and Zn concentrations indicate an increased oxidative stress in patients with acute renal diseases. **Conclusions:** Our preliminary data show that in some acute urinary conditions, such as lower urinary tract infection and pyelonephritis, appear disturbances of plasma and urinary concentrations of divalent cations. We consider that trace elements should be measured routinely in children with renal disorders. **Key words**: ZINC, COPPER, MAGNESIUM, NEPHROTIC SYNDROME

Divalent cations (calcium, magnesium, zinc, copper, manganese) play multiple roles in all human tissues and systems. These cations can be found both intracellular and extracellular and there are complex systems for their transport through the cellular membrane, and also for their concentration regulation in the human body (1, 2). The activity of more than 300 enzymes is magnesium dependent, and a similar number of enzymes are dependent of zinc.

Copper (Cu) is an essential trace element that acts as a critical cofactor when is incorporated into specific copper-enzymes that catalyze electron transfer reactions required for cellular respiration, iron oxidation, neurotransmitter biosynthesis, antioxidant defense. Copper is both a pro-oxidant and antioxidant. Its antioxidant activity has been attributed to increased CuZnSOD activity.

Zinc (Zn) is an intracellular signaling molecule and it plays an important role in cell-mediated immune functions and oxidative stress. It is also an anti-inflammatory agent and an antioxidant (3).

The human body contains 2-3 g zinc,

most of which is bound to proteins. Over 300 enzymes have been shown to contain zinc, either directly involved in catalysis, as a cofactor, or for structural stabilization. Another large group of zinc containing proteins is transcription factors. Despite its important function, the body has limited zinc stores that are easily depleted and cannot compensate longer periods of zinc deficiency.

Zinc deficiency is a cause of immune dysfunction and infection. Previous human studies have shown that the activation of the acute phase response alters zinc metabolism.

The kidney plays a significant role in magnesium homeostasis. Proximal tubular magnesium reabsorption is proportional to sodium reabsorption, and a reduction in sodium reabsorption during long-term intravenous fluid therapy may result in magnesium deficiency.

Different acute or chronic renal disorders in children or adults modify the urinary excretion of these cations and may influence their concentrations in organism (4, 5). At present there are little data about how the therapy administrated in nephrotic syndrome influences the concentration of divalent cations. Kidney is the main elimination route for all divalent cations.

In this study we investigated the changes of some divalent cations levels (Cu, Zn, Mg, Ca) in pediatric patients with acute renal diseases.

MATERIAL AND METHODS

The study group was consisted of 18 children aged from 2 to 17 years, with acute nephropathies such as urinary tract infection and acute pyelonephritis, admitted in the nephrology clinic of Sf. Maria Children's Hospital Iasi. We collected urine and blood samples and we measured the urine and plasma levels of magnesium, zinc and copper cations through atomic absorption method. We also measured the levels of serum MDA and TAC. Serum MDA levels were measured by thiobarbituric acid method and for TAC determination we used RANDOX kit. The same measurements were carried out as well for a control group consisted of 10 children aged from 2 to 15 years, with a normal health status.

RESULTS

Plasma levels of copper were decreased with 11% in children with renal disorders in comparison with control group, and plasma levels of zinc were decreased with 18% ($p<0.01$). Urinary levels of Cu and Zn there were significantly higher in group study compared with control group. There were found no significant modifications of the plasma or urinary magnesium concentrations between the study group and control group. MDA plasma levels (nmol/mL) were increased in patients with acute nephropathies compared with control group (2.12 ± 0.27 vs. 0.48 ± 0.15). Levels of serum TAC (mmol/L) were found significant decreased in study group in comparison with control group (1.16 ± 0.09 vs. 1.71 ± 0.14).

DISCUSSION

Our data are consistent with the literature data concerning clinical studies of divalent cation levels in renal diseases. There are few data about seric and urinary divalent cations changes related to renal diseases.

A study performed on 105 pediatric patients with nephrotic syndrome or nephritis-nephrosis which evaluated plasma zinc

concentration and quantitative urinary zinc excretion showed that the plasma level was decreased with 39% in patients with nephrotic syndrome compared with the control group. The rate of urinary zinc excretion was not different from that of the controls, with the exception of patients whose disease was in the polyuric phase of beginning remission where it was fivefold higher and those who had achieved a long-lasting remission of the disease (6).

Another study that investigated the effect of proteinuria on urinary zinc and copper excretion in children with nephrotic syndrome (NS) revealed that clearance, fractional excretion, and urinary excretion of zinc and copper were significantly higher in children with relapse of NS than in children with remission of NS or in healthy children. The authors found a linear correlation between proteinuria and urinary zinc and copper excretion in relapse of NS. The results of the study suggested that zinc and copper deficiency in NS may be related also to increased urinary zinc and copper losses (7). Since about two thirds of the plasma zinc is bound to albumin, an unchanged zinc-albumin ratio would reflect an equal zinc and albumin loss.

Some authors evaluated copper, zinc, calcium and magnesium concentrations in plasma, erythrocytes and urine in patients with chronic renal failure. They revealed significant plasma hypozincaemia and hypozincuria in uremic patients (though the erythrocytes zinc concentration was significantly higher than in controls), increased erythrocytes copper levels, significant hypocalcemia in erythrocytes and plasma, magnesium levels being increased (8).

The causes of Zn deficiency in kidney disease are not clear. Decreased dietary Zn intake and intestinal absorption, increased endogenous Zn loss, and increased urinary Zn excretion (as in the nephrotic syndrome) all may contribute to altered Zn metabolism (9).

The benefit of the administration of Zn doses requires further evaluation under controlled conditions. Some researchers showed that in children (1-16 years) with steroid-sensitive nephrotic syndrome, zinc administration (10 mg/day) reduced by 20% the frequency of relapses. The patients which received zinc developed a significantly higher likelihood of sustained remission (10).

Another study performed on 14 children with nephrotic syndrome showed that the mean blood zinc level was significantly lower than that of 113 control children. The blood albumin/zinc ratio was also lower in nephrotic children than in healthy children. There was no correlation between blood albumin and blood zinc levels. The authors suggested that abnormally low zinc levels are partly due to deficient zinc uptake and may explain some of the disorders described in children with persistent nephrotic syndrome (11).

The comparison of the status of zinc and copper in chronic hemodialysed patients with and without diabetes showed that the alteration in the distribution of zinc in patients with chronic kidney disease is independently of the presence of diabetes and also the status of copper seems not to be influenced by chronic kidney disease, but only by the metabolic derangements associated with diabetes (12).

Oxidative stress has been proposed as one of the possible mechanism involved in the nephrotic syndrome. Peroxidation of lipid membranes raises the concentration of their byproducts malonyldialdehyde (MDA) and

the consequent lowering of antioxidants (13). Total antioxidant capacity (TAC) is involved in antioxidant protection in nephrotic syndrome (14). In the kidney, oxygen radical production has been detected in vascular cells, juxta glomerular cells, tubular cells, podocytes, mesangial cells and isolated glomeruli. Free radicals have a negative influence on renal tissue in nephrotic syndrome.

There are studies that investigated oxidant and antioxidant status of copper, zinc and homocysteine (HCY) in nephrotic syndrome patients and the effect of antioxidants, mineral and B-complex vitamins on oxidant and antioxidant status. Results showed a significant statistically decreased level of serum TAC, Cu, Zn, plasma Vit C while serum malonyldialdehyde and homocysteine level were increased in nephrotic syndrome patients compared with control. The level of serum homocysteine and MDA were significantly decreased and activity of serum TAC, Cu, Zn was significantly increased after 3 months with Zincovit (15).

Data suggest that it can appear a relative deficit of oxidant/antioxidant balance in nephrotic syndrome, which could predispose to increased oxidative stress.

In many diseases, zinc deficiency may complicate the clinical features; affect adversely immunological status, increases oxidative stress and increase the generation of inflammatory cytokine. It is therefore important that the status of zinc to be evaluated. Alterations in zinc metabolism in some disease conditions must be studied taking into account the links between homeostatic perturbation and cellular biology, for to characterize zinc distribution and for elucidate the regulatory processes and the factors to which they respond (16).

Copper deficiency has been documented in conditions predisposing to excessive copper losses. Urinary losses of ceruloplasmin-bound copper likely play a significant role in predisposing patients with nephrotic syndrome to copper deficiency (17). Renal patients undergoing continuous ambulatory peritoneal dialysis may also experience excessive losses of ceruloplasmin-bound copper via dialysis exchanges.

Copper imbalances in humans not only impair normal function of ceruloplasmin, superoxide dismutase or of other copper-dependent proteins, but can also lead to disease states (18).

Hypomagnesemia is occasionally observed in chronic renal failure due to an obligatory renal magnesium loss. It is also seen during the diuretic phase of acute renal failure, in post-obstructive diuresis and after renal transplantation. Patients on continuous ambulatory peritoneal dialysis develop hypomagnesaemia when low magnesium dialysis fluid is used.

CONCLUSIONS

Our data show that in acute urinary diseases occur some cationic imbalances which may influence the clinical manifestations and development of the renal disease and these imbalances should be corrected.

Oxidative stress may be one of the possible mechanisms involved in the nephrotic syndrome.

We consider that the decrease of plasma zinc concentration may be involved in the immune dysfunction associated with nephrotic syndrome.

The knowledge of bivalent cations misbalances may open new ways in the treatment of nephrotic syndrome and in the reduction of some side effects of drugs usually used in treatment.

FACTORS INVOLVED IN MICROBIAL COLONIZATION OF ACRYLIC RESINS (Abstract): The objective of this study was to evaluate the effect of polishing technique and the polymerisation type on the microbial colonization of acrylic resins. **Material and methods:** The studied resins were: Castapress/Vertex, Prothyl Hot/Zermack, Duracryl Plus/Spofa Dental, Vertex-Soft/Vertex, Superacryl Plus/Spofa Dental. Ten specimens, two for every resin, presenting dimensions of 50/25/2 cm were done. One sample of each resin was polished with extrahard tungsten carbide burs, the other sample being polished with extrahard extrafine and diamond burs. The final polishing was done using a conventional method: pumice, water and lathe bristle brush for 90 seconds, 1500 rpm and soft leather polishing wheel for 90 seconds, 3000 rpm. One sample of Duracryl Plus was glazed after polishing with Glaze™/Bosworth. Vertex Soft specimens were not polished because it is a resilient material. The samples were immersed in human saliva for 24 hours and after that were colored with May Grunwald Giemsa (MGG). The total germs number (TGN) was determined by Buiuc method. **Results:** The lowest value of the microbial colonization was related to the heat-curing resins treated by conventional polishing combined with glazing techniques. **Conclusions:** The results noticed that the type of acrylic resin (autopolymerizing and heat-cured) and the polishing techniques have a significant influence on the microbial colonization. Specimens of self curing resin had a higher porosity than heat curing resin after the same surface treatment, generating a higher TGN. **Key words**: ACRYLIC RESINS, TGN, POLISHING TECHNIQUE, MICROBIAL COLONIZATION

Pentru prevenirea colonizării bacteriene şi a acumulării plăcii pe suprafeţele protezelor dentare trebuie acordată o importanţă deosebită stării de suprafaţă a acestora, în mod special feţei mucozale, sursă frecventă a stomatitelor paraprotetice. În acest scop protezele amovibile trebuie să aibă suprafeţe netede şi bine lustruite pentru a menţine confortul şi sănătatea ţesuturilor orale (1).

După introducerea în cavitatea orală proteza este rapid acoperită de o peliculă salivară dobândită (maximum 2 ore), compusă dintr-un strat selectiv de componente salivare adsorbite (în special glicoproteine) care au un rol important în modularea colonizării microorganismelor.

Scopul studiului a constat în analiza prin microscopie optică a gradului de colo-

nizare bacteriană a cinci răşini acrilice, cu regim de polimerizare diferit (autobaropolimerizare şi termopolimerizare), care au fost supuse la prelucrări mecanice diverse.

MATERIALE ŞI METODE

Răşinile studiate au fost alese dintre cele mai frecvent utilizate în protetica dentară: *Castapress/Vertex, Prothyl Hot/Zermack, Duracryl Plus/Spofa Dental, Vertex-Soft/Vertex, Superacryl Plus/Spofa Dental*. S-au realizat zece probe, câte două pentru fiecare tip de material.

Probele au fost realizate sub formă de plăcuţe paralelipipedice cu lungimea de 50 mm, lăţimea 25 mm şi grosimea 2 mm. Machetele plăcuţelor au fost transformate în probe finale respectând algoritmul tehnologic specific şi indicaţiile firmei producătoare pentru fiecare tip de răşină (tab. I). Probele au fost notate cu literele A-E, respectiv A'-E'.

TABELUL I

Regimul de polimerizare al răşinilor studiate

Proba	Denumirea comercială	Regimul de polimerizare
A, A'	Castapress/ Vertex	30 minute la 55º C şi 2.5 bar
B, B'	Prothyl hot/Zermack	5 minute de la 80° la 100°C + 20 minute la 100°C
C, C'	Duracryl Plus/Spofa Dental	30 - 40°C / 0,2 - 0,3 MPa.
D, D'	Vertex Soft	3 ore la 70º C, urmat de 30 de minute la 100ºC
E, E'	Superaryl Plus (Spofa Dental)	Temperatura creşte în 30 minute până la 70ºC, 30 minute se menţine la 70ºC, urcă în 30 minute până la 100ºC, 30 minute rămâne la 100ºC

Prelucrarea şi lustruirea celor două probe din fiecare tip de răşină s-a făcut utilizând tehnici diferite, viteza şi timpul de prelucrare fiind însă identice (30 de secunde, 1500 rpm).

Prelucrarea mecanică s-a făcut cu o freză extradură din carbură de tungsten cu granulaţie fină (galbenă) pentru probelele: A, B, C, D şi E iar pentru probelele A', B', C', D' şi E' prelucrarea s-a făcut atât cu o freză extradură cu granulaţie extrafină (53-63 μ) de formă conică, cât şi cu o freză diamantată cu granulaţie fină (roşie) de formă cilindrică, cu vârful rotunjit.

Lustruirea finală a avut ca obiectiv obţinerea unui "luciu de oglindă" şi s-a realizat cu praf abraziv pentru lustruit (*Polishing powder/Astar Fedent*) şi pastă abrazivă (*High lustre polishing paste*) acţionate de perii şi filţuri.

Probele D şi D' fiind dintr-un material rezilient, care se utilizează doar pe suprafaţa mucozală a protezei, au beneficiat de o prelucrare uşoară cu praf *Vertex™ Soft*. Lustruirea a fost făcută cu praf abraziv (*Astar-Fedent*) şi pastă abrazivă, încărcate pe un con din pâslă (filţ) şi puf de bumbac.

Proba C a fost acoperită cu o peliculă de glazură fotopolimerizabilă pentru răşini acrilice şi materiale compozite (*Bell Coat/ K B Mutsumi*), care a fost aplicată prin pensulare în strat subţire pe suprafaţa uscată a probei şi apoi fotopolimerizată patru minute.

Saliva a fost obţinută de la un singur pacient, în vârstă de 43 de ani, sănătos din punct de vedere clinic, care nu a urmat nici o terapie medicamentoasă în ultimele trei luni, şi nu a utilizat nici soluţii pentru clătiri orale, care ar fi putut modifica compoziţia şi secreţia salivară.

Obiectivele urmărite au vizat determinarea încărcăturii microbiene a salivei recoltate şi determinarea încărcăturii microbiene a biofilmului salivar de pe supra-

fețele probelor luate în studiu.

Metoda de lucru a constat în:

- dezinfecția probelor prin imersie timp de 1 oră în soluție Zeta 1 Ultra
- menținerea probelor în salivă timp de 24 ore
- aprecierea gradului de contaminare microbiologică a probelor analizate s-a realizat prin metoda cultivării în plăci Petri (2), utilizându-se agar nutritiv (Merck, Germany). Obținerea inoculului s-a realizat prin spălarea repetată a probelor cu 5 ml apă distilată sterilă. Pentru inoculare s-a utilizat un volum de 100 µl inocul/placă Petri, iar în cazul periei s-a efectuat însămânțarea atât prin spălare cât şi prin amprentare.
- incubarea (24 ore la 37°C) a fost urmată de o apreciere cantitativă a încărcăturii microbiene.
- colorarea panoptică May Grunwald Giemsa (MGG) a probelor pentru vizualizarea adeziunii bacteriene cu ajutorul microscopiei optice (M.O).

REZULTATE ŞI DISCUȚII

Valoarea NTG/ml din saliva recoltată a fost de 46 x 10^{10} iar valorile NTG probelor au fost cuprinse între 0,16 x 10^8 UFC/cm^2 – 12,1 x 10^8 UFC/cm^2 (fig. 1).

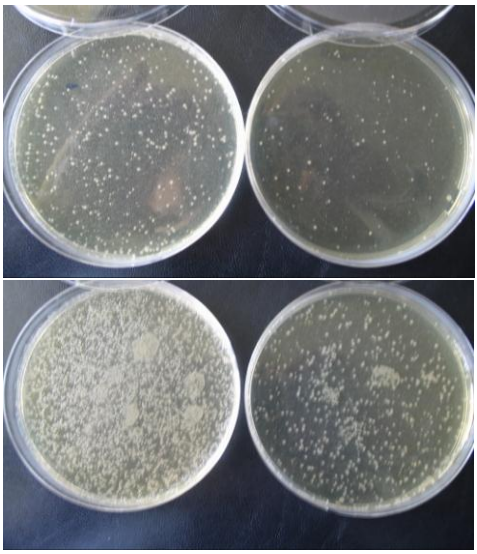

Fig. 1. Determinarea NTG-ului

Cea mai mică valoare (0,16 x 10^8) s-a întâlnit la proba C (glazurată), ceea ce demonstrează faptul că deşi glazurarea nu poate preveni colonizarea bacteriană, modifică semnificativ cantitatea microorganismelor care aderă la suprafața respectivă (fig. 2).

a. 
b. 
Fig.2.a. Proba C = 0,16 x 10^8 UFC/cm^2 b.Proba C'=1,65 x 10^8 UFC/cm^2 (magnificație X 50)

Corelând rezultatele colonizării bacteriene cu metoda de prelucrare folosită, se observă diferențe între probele care au fost prelucrate numai cu freza extradură şi cele care au fost prelucrate atât cu freza extradură cât şi cu freza diamantată, chiar dacă metoda de lustruire a fost aceeaşi pentru toate probele (tab. II).

TABELUL II

Corelația încărcătură bacteriană/regimul de polimerizare a rășinilor studiate

Proba	Tipul de polimerizare	Colonizarea bacteriană UFC/cm^2
A	Vertex castapress autopolimerizare	1.76 x 10^8
A'	autopolimerizare	1.68 x 10^8
B	Prothyl Hot termopolimerizare	1.46 x 10^8
B'	termopolimerizare	1.11 x 10^8
C	Duracryl autopolimerizare, glazurare	0.16 x 10^8
C'	Duracryl autopolimerizare	1.65 x 10^8
D	Vertex soft termopolimerizare, rezilienţă	12.1 x 10^8
D'	Vertex soft termopolimerizare	12.1 x 10^8
E	Superaryl Plus (Spofa Dental)	1.01 x 10^8
E'	Superaryl Plus (Spofa Dental)	0.83 x 10^8

Valoarea cea mai mare înregistrată în cazul probelor din *Vertex Soft* (12.1 x 10^8 UFC /cm^2), este în acord cu datele din literatură care precizează că rășinile reziliente au textură spongioasă, ce antrenează creşterea porozității şi implicit, a colonizării bacteriene, limitând longevitatea clinică a materialului (3).

De asemenea, studiind corelația dintre regimul de polimerizare şi colonizarea microbiană, am observat că rășinile acrilice autopolimerizabile prezintă valori mai mari ale încărcăturii microbiene .

În ceea ce priveşte colonizarea rășinilor acrilice glazurate, rezultatele obținute au fost net superioare probelor neglazurate. Sesma N. şi col., 2005 (4) a demonstrat printr-un studiu clinic că protezele prezentau la o lună după glazurare o peliculă mai subțire de placă bacteriană comparativ cu cele neglazurate. Reevaluarea după 3 luni, a arătat că glazura a fost fisurată, generându-se arii microretentive ce au determinat acumularea plăcii bacteriene. Aceste constatări au condus la concluzia că eficiența glazurării este condiționată de păstrarea integrității stratului depus.

Totuşi, literatura de specialitate prezintă opinii diferite cu privire la relația de dependență (directă sau indirectă) între rugozitatea suprafeței şi colonizarea bacteriană. Astfel Von Fraunhofer şi col., 2009 (5) afirmă că „este posibil" ca rugozitatea suprafeței să ofere un mediu care promovează atracția inițială a colonizării timpurii. Oricum, formarea biofilmului depinde de mai mulți factori, cu o importanță specială fiind speciile bacteriene, natura substratului şi factorii de mediu înconjurător. Există însă şi numeroase studii care demonstrează o relație liniară între aceşti doi parametri (6, 7, 8, 9).

Analiza încărcăturii microbiene a probelor face apel la un număr de variabile cunoscute ale materialului (rugozitate, umectabilitate, tip de polimerizare) care trebuie corelate cu multitudinea variabilelor ce definesc „mediul salivar”.

Prin urmare este dificilă compararea rezultatelor diferitelor studii, datorită protocoalelor diferite utilizate: perioadelor diferite de incubație, utilizării de salivă totală sau parțială, condițiile unui flux salivar stimulat sau nestimulat, temperaturilor diferite ale salivei, precum şi prezența sau absența nutrienților care pot interfera cu viabilitatea celulară şi capacitatea ei de aderare.

CONCLUZII

Cea mai mică valoare a încărcăturii microbiene ($0{,}16 \times 10^8$) s-a întâlnit la proba C (glazurată), ceea ce demonstrează că glazurarea modifică semnificativ cantitatea microorganismelor care aderă la suprafața protezei.

Cea mai crescută valoare a încărcăturii microbiene (12.1×10^8 UFC/ cm^2) s-a întâlnit la proba D (răşină rezilientă) datorită texturii spongioase a răşinii.

Valorile încărcăturii microbiene sunt mari în cazul răşinilor acrilice autopolimerizabile, în timp ce răşinile termopolimerizabile prezintă valori mai mici.

Probele care au beneficiat de prelucrare cu freza extradură au valori mai crescute ale încărcăturii microbiene comparativ cu cele prelucrate cu freza extradură şi diamantată.

FACTORI PROGNOSTICI ÎN CANCERUL MAMAR

R. Georgescu, M. F. Coroş, Simona Stolnicu, Daniela Podeanu, S. Sorlea, Anca Roşca, C. Copotoiu
Universitatea de Medicină şi Farmacie Târgu Mureş

PROGNOSTIC FACTORS IN BREAST CANCER(Abstract): Survival in breast cancer is determined by many factors, their influence is different. The aim of the study is to assess the impact on survival of various prognostic factors. **Material and methods**: We studied a total of 198 cases of histologically confirmed breast cancer patients, and we evaluated the impact of prognostic factors on survival. **Results:** The most important factor influencing survival is the preset of axillary metastasis(p: 0.0001). Other important prognostic factors are: tumor size(p: 0.003), tumor *grading*(p: 0.0025), N stage(p: 0.0001.) lymphovascular invasion (p 0.0005) and Nottingham Prognostic Index(p: 0.0109). The factors with no impact on survival were: histological type(p: o,82), number of lymph nodes affected(p: 0,23), tumor necrosis(p: 049) and inflammatory infiltration (p:0,2). **Conclusions:** The most important prognostic factors are: axillary metastasis followed by tumor *grading*, NPI and lymphovascular invasion.
Key words: BREAST CANCER, PROGNOSTIC FACTORS, SURVIVAL.

Cancerul mamar reprezintă o problemă de larg interes pentru sănătatea populațională. Metodele de depistare precoce, tratamentul chirurgical şi oncologic au reuşit să îmbunătățească prognosticul pacienților suferinzi de neoplazie mamară (1, 2).

Factorii care influențează prognosticul în cancerul mamar sunt multipli, iar importanța lor este diferită. Stabilirea riscului de recidivă şi metastazare este important nu doar pentru a putea prevedea evoluția pacientului, ci permite cuantificarea beneficiului pentru tratamentul adjuvant. Pacienții cu risc major de recidivă şi metastazare au o indicație majoră de a urma tratamentul complementar chimio şi radioterapic, cu un raport risc/beneficiu minim. Noile metode de investigație genetică vor permite definirea clară a pacientelor care necesită tratament adjuvant şi inclusiv chimio şi radiosensibilitatea acestora, ceea ce va diminua riscurile supratratamentului (3, 4).

Se deosebesc două tipuri de factori care pot influența evoluția pacienților cu cancer mamar: factorii prognostici care prin definiție sunt aceia care ne oferă informații despre evoluția potențială a pacienților în absența tratamentului adjuvant sistemic şi factorii predictivi care reprezintă răspunsul la un anumit tratament sistemic (de exemplu receptorii estrogenici pentru terapia antihormonală) (5, 6).

MATERIAL ŞI METODE

Studiul a inclus 300 de paciente cu cancer mamar confirmat histologic şi care au suferit o intervenție chirurgicală radicală sau conservatoare. Datele au fost obținute din registrul cu rezultate histopatologice şi din foile de observație, iar pacientele au

beneficiat de control în urma unei scrisori de invitație. În cazul decesului pacientelor, am solicitat date referitoare la cauzele şi data decesului. Procentul de răspuns a fost în jurul cifrei de 70%. De asemenea, s-au acumulat date din registrele Fundației "Destine Comune" a pacientelor operate de cancer mamar precum şi cele privind supraviețuirea şi cauzele de deces obținute de la Clinica de Oncologie, Târgu Mureş.

Pentru 198 de paciente am putut obține date satisfăcătoare. În studiul retrospectiv am comparat influența diverşilor factori prognostici asupra supraviețuirii: vârsta, tipul histologic, *grading*-ul tumoral, dimensiunea tumorii, metastazarea limfatică axilară, indicele prognostic Nottingham, infiltratul inflamator, necroza tumorală, invazia limfo-vasculară şi grupa sangvină. Rezultatele studiului au fost analizate statistic cu ajutorul programului Graphpad demo folosind curbele de supraviețuire Kaplan Meier.

REZULTATE

1. Vârsta pacientelor. Lotul de studiu a avut limita de vârstă 40 - 50 de ani, fără a se dovedi influența asupra prognosticului. Semnificația statistică a evidențiat un p de 0,94 pentru 40 respectiv 0,13 pentru 50 de ani (fig. 1).

2. Tipul histologic. Cel mai frecvent întâlnit a fost carcinomul ductal invaziv prezent la 141(71,21%), urmat de carcinomul lobular prezent la 51(25,75%) din cazuri. Supraviețuirea la 5 ani a fost de 74,46% pentru carcinomul ductal şi de 68,4% pentru cel lobular invaziv. Datele nu prezintă semnificație statistică (p 0,82). Am studiat influența asocierii dintre carcinomul ductal invaziv şi cel *in situ*, supraviețuirea acestor forme fiind mai mare la 5 ani (86%) decât la formele invazive pure (72%)(p = 0,04) (fig. 2).

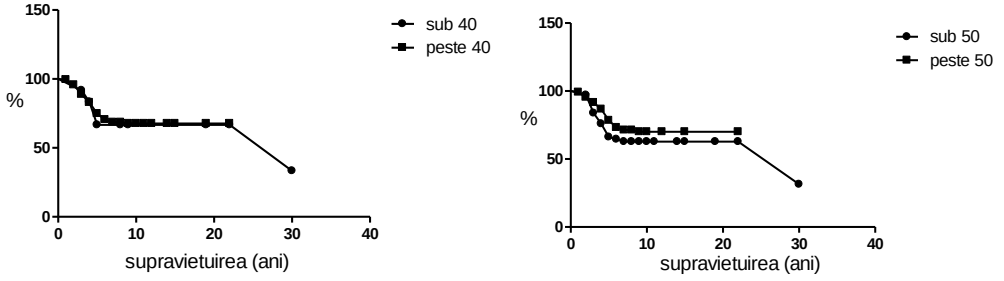

Fig. 1. Nivelurile supraviețuirii celor două grupuri de vârstă din lotul luat în studiu.

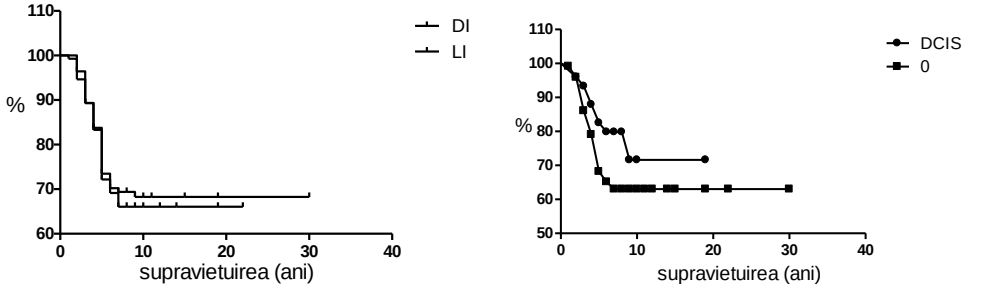

Fig. 2. Evaluări comparative a supraviețuirii la pacientele incluse în studiu.

3. Grading-ul tumoral. Din punct de vedere al supraviețuirii, *grading*-ul tumoral a avut un impact hotărâtor, astfel, supraviețuirea la 5 ani în Gr I a fost de 92,8%, Gr II 78,4 %, iar Gr III 64,7 %, datele având o înaltă semnificație statistică cu un p de 0.0025 (fig. 3), iar supraviețuirea la 5 ani în relație cu stadiul tumoral este redată în tabelul I.

TABELUL I

Stadiul tumoral	Supraviețuirea la 5 ani %
0, I	100
II A	90
II B	80,7
III A	65
III B	52
IV	0

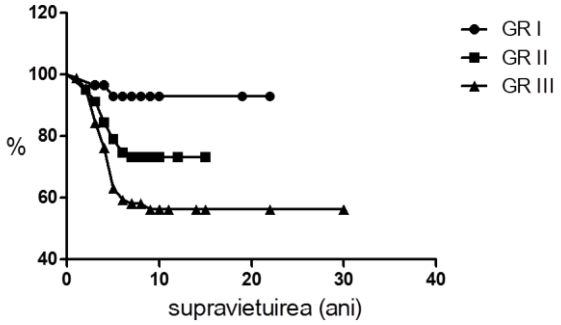

Fig. 3. Nivelurile supraviețuirii în relație cu *grading*-ul tumoral.

4. Metastazele ganglionare. În lotul studiat, un număr de 79 paciente (39,89%) nu au prezentat adenopatii metastatice, în timp ce acestea au fost întâlnite la 119 paciente (60,1%). Într-un singur caz nu s-a practicat limfadenectomie, pacienta prezentând metastaze la distanță, gestul terapeutic s-a limitat la mastectomie de curățire. Supraviețuirea la 5 ani în lotul N0 a fost de 94,5 %, iar N+ a beneficiat de o supraviețuire de 62,18%(p de 0,0001). Comparând supraviețuirea pacientelor din punctul de vedere a stadiului N am găsit o diferență semnificativă statistic între loturile N1 şi N2 (p = 0,0001) (fig. 4).

Impactul asupra supraviețuirii în raport cu numărul de ganglioni afectați având ca reper cifra 3, respectiv 5, nu a evidențiat diferențe semnificative statistic (p = 0,23; respectiv 0,07) (fig. 5).

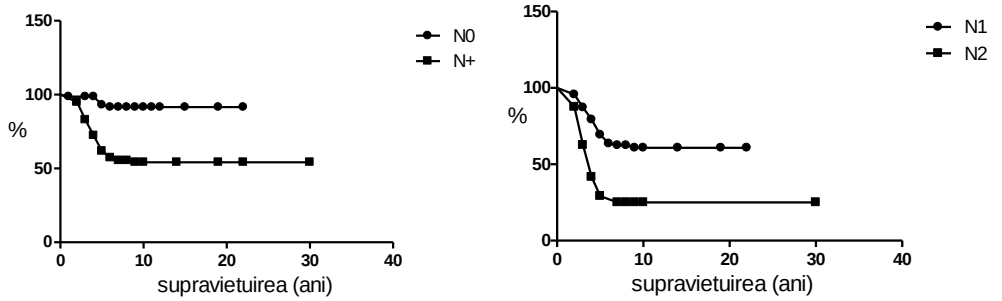

Fig. 4. Evaluarea privind supraviețuirea la 5 ani pe două loturi de paciente.

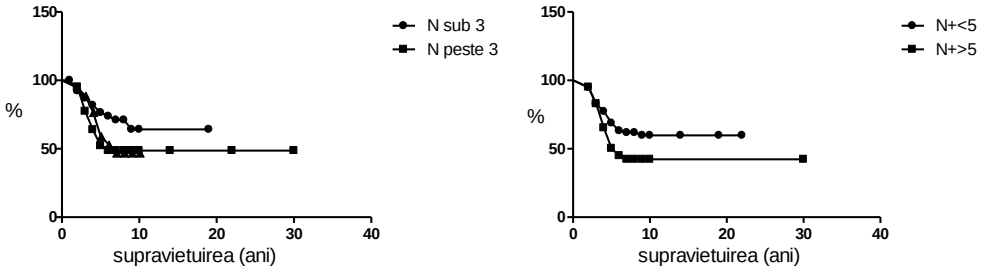

Fig. 5. Analiza duratei de supraviețuire în relație cu numărul ganglionilor afectați de metastaze.

5. Dimensiunea tumorii şi stadiul T. Datele obținute de noi au fost controversate, astfel s-a observat o semnificație statistică mai ales pentru stadiul T4 şi T1(p = 0,003), iar pacientele cu tumori aflate în stadiul T2 şi T3 au avut curbe de supraviețuire aproximativ superpozabile (fig. 6).

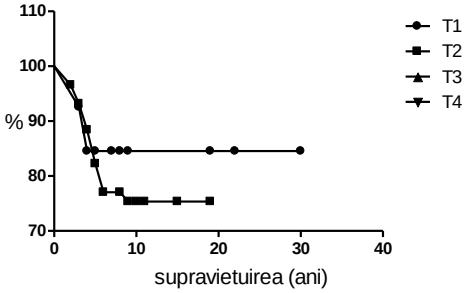

Fig. 6. Comparații între stadiile evolutive ale tumorii.

6. Indicele prognostic Nottingham. S-a folosit formula de calcul al NPI: 2 x dimensiunea tumorii în cm + stadiul N (1-3) + *grading*-ul tumoral (1-3). Lotul studiat a fost subîmpărțit în NPI sub şi peste 5, diferența rezultând că pacientele cu NPI peste 5 au o mortalitate la 5 ani mai mare, semnificativ statistic (p 0,0109).

Infiltratul inflamator peritumoral este considerat un factor de protecție fiind manifestarea unui răspuns imun puternic. În cazuistica studiată formele cu infiltrat inflamator au avut un prognostic mai bun dar fără semnificație statistică (p 0,2) (fig. 7).

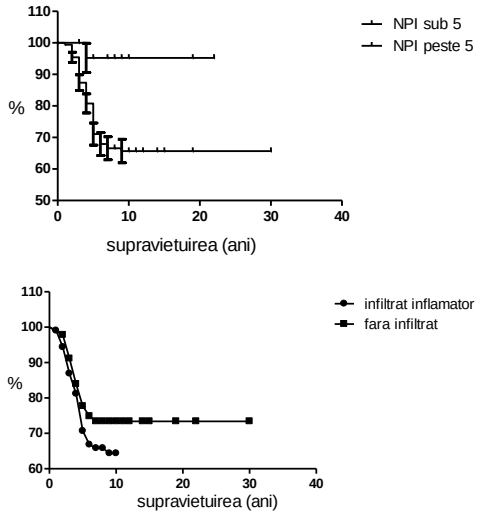

Fig. 7. Evaluarea asupra unor caracteristici ale tumorii cu valoare prognostică.

Prezența invaziei vasculare are o semnificație negativă atât asupra prognosticului imediat cât şi a celui la distanță. Pe lotul studiat, un număr de 55 (27,77%) paciente au prezentat invazie vasculară iar la 143 (72,22%) aceasta a fost absentă. Cu ajutorul curbelor de supraviețuire s-a stabilit o corelație importantă între invazia limfo-vasculară şi supraviețuirea la 5 ani (p = 0,0005).

Necroza tumorală se datorează creşterii rapide a unei tumori care depăşeşte capacita-

tea acesteia de a se vascularizа, ca urmare, este considerată a fi un tip tumoral cu evoluţie nefavorabilă (indice mitotic crescut). Cazurile cu necroză din lotul studiat au beneficiat de o durată de supravieţuire mai redusă fără semnificaţie statistică (p = 0,49) (fig. 8).

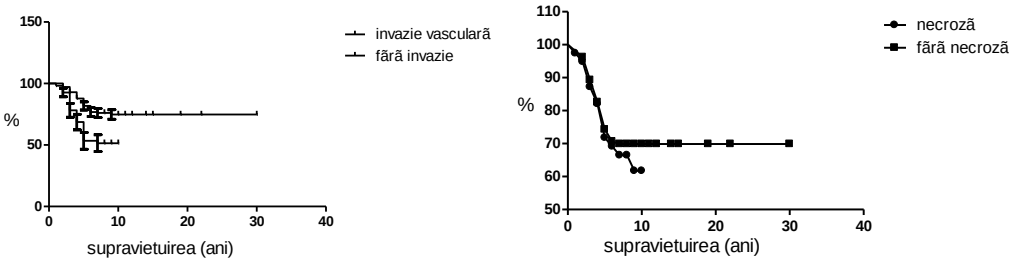

Fig. 8. Aspecte ale prognosticului dependent de invazia vasculară şi de necroza tumorală.

Relaţia dintre grupul sangvin asupra supravieţuirii pacientelor cu cancer mamar nu a evidenţiat rezultate cu semnificaţie statistică (p = 0,71).

Studiul multifactorial a determinat care dintre factorii clasici de prognostic: stadiul T, metastazarea axilară sau *grading*-ul tumoral au o influenţă mai importantă asupra supravieţuirii pacientelor cu cancer mamar. S-a evidenţiat faptul că deşi toţi factorii enumeraţi influenţează statistic semnificativ supravieţuirea, impactul cel mai important îl are metastazarea limfatică axilară (tab. II).

TABELUL II

Term	Odds ratio	95%	C. I.	Coeficient	S. E.	Z-Statistic	P-Value

DISCUŢII

Han et al (1) a demonstrat faptul că vârsta sub 35 de ani la debutul neoplaziei mamare reprezintă un semnal de alarmă atât pentru recidivă cât şi pentru supravieţuirea tardivă. După El-Saghir et al (2) vârsta tânără nu pare să fie un factor decisiv pentru recidivă la grupul cu ganglioni negativi, dar influenţează major recidiva, metastazarea şi supravieţuirea la pacientele cu adenopatii tumorale. În lotul studiat vârsta nu s-a dovedit un factor semnificativ pentru supravieţuire luând în consideraţie că numărul de cazuri cu vârstă sub 40 de ani a fost redus.

Black et al.(3) într-un studiu cu variabile multiple au corelat tipul histologic cu gradul de malignitate şi au constatat ca fiind mai important din punct de vedere al semnificaţiei prognostice *grading*-ul tumoral. De asemenea, McCready et al(4) subliniază importanţa *grading*-ului tumoral pentru evaluarea supravieţuirii la 5 ani a pacientelor cu cancer mamar. Studiul nostru apreciază *grading*-ul tumoral ca fiind un factor prognostic cu o semnificaţie statistică importantă dar în ceea ce priveşte tipul histologic nu relevă o diferenţă de supravieţuire între formele ductale şi lobulare invazive. Nu putem explica de ce asocierea cu formele *in situ* oferă un plus de supravieţuire la pacientele cu carcinom ductal invaziv.

Prezenţa metastazelor axilare este considerat un semn de boală avansată cu efecte

importante asupra supraviețuirii. Deşi numărul de ganglioni limfatici afectați de metastaze nu a avut o influență semnificativă asupra supraviețuirii gradul N, respectiv extensia extracapsulară, au un impact important asupra supraviețuirii fapt confirmat şi de studiile lui Maksimovici et al (5).

Din studii prospective largi s-a demonstrat că pacientele cu NPI mai mic de 3-4 au o mortalitate anuală egală cu populația generală, ca urmare, nu necesită tratament oncologic suplimentar, pe când cele cu valori ale indicelui de peste 5 au o rată de supraviețuire mult mai redusă, ca urmare, beneficiază de tratament oncologic. Studiul nostru a confirmat importanța NPI în evaluarea prognosticului (6).

Majoritatea studiilor actuale consideră metastazele axilare ca fiind factorul prognostic cel mai important, fapt confirmat de evaluarea multifactorială care conferă acestui factor cea mai importantă semnificație statistică.

CONCLUZII

Principalul factor de prognostic, cu semnificația statistică cea mai ridicată s-a dovedit a fi statusul ganglionar N, astfel cazurile cu metastaze ganglionare au beneficiat de o supraviețuire mai redusă decât cele N0. Numărul ganglionilor afectați nu pare a avea semnificație, dar stadiul afectării ganglionare N1 sau N2 (deci invazia extraganglionară) s-a dovedit a fi un factor important asupra supraviețuirii.

Tipul histologic ductal sau lobular nu s-a dovedit important din punct de vedere al supraviețuirii dar are importanță pentru enunțarea deciziei terapeutice

Carcinomul *in situ* pare a avea un efect protector, deşi componenta *in situ* extensivă ridică probleme deosebite pentru abordarea conservatoare datorită extensiei de-a lungul canalelor galactofore peste limita palpabilă.

Dimensiunea tumorii (în cm) nu este un factor semnificativ dar mai important este stadiul tumoral T, respectiv invazia tegumentului sau peretelui toracic.

Grading-ul tumoral este un factor prognostic independent cu influență hotărâtoare asupra supraviețuirii.

Invazia limfo-vasculară influențează atât apariția metastazelor ganglionare cât şi supraviețuirea la distanță dar necroza tumorală şi infiltratul inflamator peritumoral nu pare a avea o influență semnificativă statistic.

În lotul studiat s-a dovedit că factorii cu cel mai nefavorabil impact asupra supraviețuirii sunt: metastazele ganglionare, *grading*-ul tumoral, stadiul T şi invazia limfovasculară.

CONTRIBUŢII LA EVALUAREA STATUSULUI HEMODINAMIC ÎN SINDROMUL METABOLIC

Livia Pădure[1], Ileana Sînziana Ignat[1], Irina Eşanu[2], J. Hurjui[3]

CONTRIBUTIONS TO THE ASSESSMENT OF HEMODYNAMIC STATUS IN METABOLIC SYNDROME (Abstract): The concept of normohemodynamics is based on the fact that the main function of the cardiovascular system is the transport of oxygen. The cardiovascular system is adapting to a new hemodynamic status with every heartbeat. Only one class, called the normohemodynamic state, containing a simultaneous normotension and normodynamic flow, can serve as therapeutic goal. Metabolic syndrome includes a constellation of clinical and biological features that confer an increased cardiovascular risk. Clutter hemodynamic modulators in metabolic syndrome and assessment of hemodynamic status both overall and by its components, open new perspectives in the management of patients with hypertension and metabolic syndrome. **Material and methods**: In the current study were included 32 patients meeting the criteria for metabolic syndrome and hypertension and 32 controls. Patients were monitored and assessed for the global hemodynamic status and for the modulators of hemodynamics, intravascular volume, vasoactivity and inotropy, respectively. **Results and conclusions:** There are no significant differences in the global hemodynamic status between the study group and the control group; in the study group there is a clear weathering of hemodynamic modulators. The improvement of these factors opens a new perspective in the global cardiovascular assessment and therapeutic directions. **Key words**: HEMODYNAMIC STATUS, DISORDERS, MODULATORS, METABOLIC SYNDROME, HYPERTENSION

Rolul esenţial al sistemului cardiovascular este să asigure transportul de oxigen şi nutrienţi către ţesuturi, nivelurile adecvate ale DO2I (Oxygen Delivery Index) fiind corelate cu supravieţuirea şi calitatea vieţii (1). Transportul oxigenului se află în relaţie cu fluxul sangvin şi nu cu presiunea sangvină deoarece sistemul cardiovascular se adaptează la un nou status hemodinamic cu fiecare bătaie a cordului iar hemodinamica evaluează elementele inseparabile flux/presiune (2).

Variaţiile indexului sistolic (IS) reprezintă cauza principală a modificărilor hemodinamice continui; variaţiile frecvenţei cardiace reprezintă răspunsul compensator cronotrop pentru a menţine fluxul de perfuzie constant (3).

Măsurarea indexului cardiac se realizează prin termodiluţie, metodă invazivă care exprimă valoarea medie a debitului cardiac pe perioada de diluţie (aproximativ 12 bătăi ale cordului), din care poate fi calculată

valoarea medie a IS sau prin bioimpedanţa electrică toracică (BET), metodă noninvazivă bazată pe rezistenţa ţesuturilor la frecvenţa ridicată a unui curent electric de magnitudine redusă. Principiul acestei tehnici se bazează pe faptul că sângele este substanţa cu cea mai bună capacitate conductoare din punct de vedere electric din corp.

Parametrii măsuraţi de BET sunt: conductivitatea fluidului toracic (CFT), variaţia impedanţei cu timpul (dZ/dt max), acceleraţia fluxului aortic în relaţie cu inotropismul şi fracţia de ejecţie, frecvenţa cardiacă (FC), timpul de ejecţie ventriculară (TEV), frecvenţa respiratorie (FR). Cu ajutorul formulelor automate de calcul, se obţin valori pentru: VEPT (volumul ţesutului toracic participant electric), EPCI (index de contractilitate a fazei de ejecţie), indexul stării inotrope, debitul cardiac (cardiac output, performanţa cordului), suprafaţa corporală (SC), indexul cardiac (IC), fracţia de ejecţie şi volumul per bătaie (SV), calculat conform ecuaţiei lui Sramek.

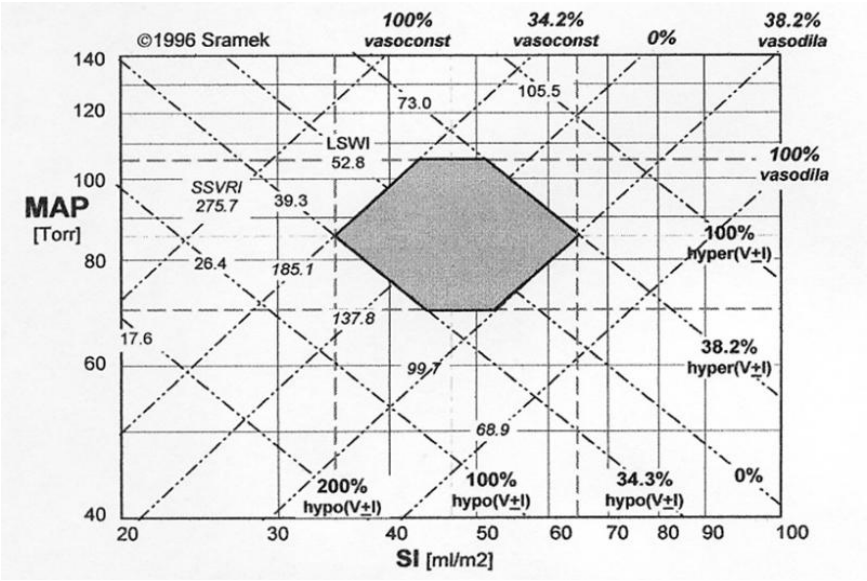

Fig. 1. Harta hemodinamică (după Sramek B.)

Relaţiile dintre statusul hemodinamic şi modulatorii hemodinamici, pentru un adult în repaus, se exprimă grafic prin harta hemodinamica ce prezintă 2 coordonate:

- sistemul ortogonal aparţinând statusului hemodinamic: presiunea arterială medie (PAM) şi indexul sistolic (IS);
- sistemul diagonal al modulatorilor hemodinamici: volemia, inotropismul şi vasoactivitatea.

Centrul hărţii reprezintă statusul hemodinamic ideal, normohemodinamica şi simultan, normovolemie, normoinotropism şi normovasoactivitate (fig. 1).

Determinarea prin BET a acestor modulatori permite identificarea dezordinilor hemodinamice şi deschide perspectiva unei terapii care să direcţioneze pacientul într-o stare de normohemodinamică şi de normoperfuzie, schimbând conceptul de medicină cardiovasculară reactivă (tratarea pacientului când afectarea hemodinamică este dia-

gnosticată) într-un nou concept de medicină cardiovasculară proactivă (5,6,7,8).

Lucrarea de faţă îşi propune să evalueze posibilităţile de determinare a statusului hemodinamic la pacienţii cu hipertensiune arterială şi sindrom metabolic.

MATERIAL ŞI METODE

Lotul de studiu a inclus 32 de pacienţi cu HTA şi sindrom metabolic iar lotul martor a fost reprezentat de 32 de pacienţi cu sindrom metabolic dar normotensivi. Criteriile de excludere au fost: obezitatea extremă, prezenţa blocului de ram drept sau a fibrilaţiei atriale, anemia sau poliglobulia. Pacienţii au fost evaluaţi prin bioimpedanţă electrică toracică.

Rezultatele obţinute au fost prelucrate şi interpretate folosind programul *SPSS 16.0* iar pentru comparaţia loturilor s-a utilizat testul "Independent Sample."

REZULTATE ŞI DISCUŢII

1. Evaluarea statusului hemodinamic global a evidenţiat că: 28 (87,5%) pacienţi din lotul de studiu au fost normohemodinamici; 2 (6,25%) hiperdinamici; 2 (6,25%) hipodinamici. Pentru lotul martor, s-a constatat că: 29 (90,62%) pacienţi au fost normodinamici; 2 (6,25%) hiperdinamici; 1 (3,12%) hipodinamic. Se observă astfel că în ceea ce priveşte statusul hemodinamic global, nu s-au înregistrat diferenţe semnificative între lotul de studiu şi cel martor.

Pentru a verifica dacă între gupurile de pacienţi există diferenţe semnificativ statistic s-a utilizat *testul t* (corelaţia mediilor studiate), care a demonstrat existenţa unei corelaţii nesemnificative pentru statusul hemodinamic global (tab. I, II).

2. Evaluarea modulatorilor hemodinamici. În lotul de studiu 11 (34,4%) pacienţi prezentau ca dezordine predominanta hipervolemia; 20 (62,5%) vasoconstricţia; 1 (3,1%) parametri normali. În lotul martor 21 (65,6%) pacienţi au prezentat parametri normali în ceea ce priveşte volemia, inotropismul şi vasoactivitatea; 3 (9,4%) hipervolemie; 8 (25%) vasoconstricţie. Pentru a verifica dacă între grupurile de pacienţi există diferenţe semnificativ statistic în ceea ce priveşte modulatorii hemodinamici s-a utilizat *testul t*. S-a observat astfel că HTA şi sindromul metabolic se corelează cu dezordini ale modulatorilor hemodinamici, deşi la o primă evaluare a statusului hemodinamic global pacienţii ar putea fi încadraţi în categoria celor normodinamici (tab. III, IV).

CONCLUZII

Sindromul metabolic este o construcţie clinic utilă în medicina prevenţională. Acesta este alcătuit dintr-o constelaţie de elemente clinice şi biologice care conferă indivizilor un risc cardiovascular crescut.

Hipertensiunea arterială este cea mai frecventă componentă individuală a sindromului metabolic şi totodată un factor cu mare susceptibilitate de a fi modificat.

S-a dovedit că bioimpedanţa electrică toracică permite evaluarea noninvazivă atât a statusului hemodinamic global cât şi a modulatorilor hemodinamici (volemie, inotropism, vasoactivitate).

S-a stabilit că HTA şi sindromul metabolic se corelează cu dezordini ale modulatorilor hemodinamici.

Evaluarea prin BET deschide perspectiva unei abordări terapeutice hemodinamice a pacienţilor cu HTA şi sindrom metabolic, care să vizeze dezordinea hemodinamică predominantă.

REZISTENȚA LA ANTIBIOTICE A *STREPTOCOCCUS PNEUMONIAE*, 2003-2009

E. Năstase[1], Olivia Dorneanu[2,3], Carmen Dorobăț[1,3]
Universitatea de Medicină şi Farmacie "Gr. T. Popa" Iaşi
Facultatea de Medicină,
1. Disciplina de Boli Infecţioase
2. Disciplina de Microbiologie
3. Spitalul Clinic de Boli Infecţioase „Sf. Parascheva" Iaşi

ANTIMICROBIAL RESISTANCE OF *STREPTOCOCCUS PNEUMONIAE*, 2003-2009 (Abstract). *Streptococcus pneumoniae* is the most important respiratory tract pathogen in otitis, sinusitis, bronchitis, and community-acquired pneumonia. **Material and methods**: A total of 155 patient isolates of *S. pneumoniae* were collected between February 2003 and December 2009 from the Iaşi „Sf. Parascheva" Infectious Diseases Hospital. Susceptibility to antibiotics was assessed by disk diffusion method (CLSI 2003-2008); minimum inhibitory concentrations (MIC) to penicillin and cefotaxime were determined by broth dilution method or E-test method. **Results**: Of these isolates, 32.6% were penicillin non-susceptible (MIC ≥ 0.12 µg/mL for nonmeningeal isolates before 2008 and all meningeal isolates and MIC ≥ 2 µg/mL for nonmeningeal isolates after 2008). The percentage of penicillin resistance increased from 0% to a maximum of 50% in 2008. Resistance rates (intermediate and resistant strains) among non-beta-lactam agents were as follows: macrolides, 30.9%; clindamycin, 9%; tetracycline, 34.3%; chloramphenicol, 2.1%; and trimethoprim-sulfamethoxazole, 57.5%. No resistance to vancomycin, linezolid and quinupristin-dalfopristin was observed. Resistance to non-beta-lactam antibiotics was higher among penicillin-resistant strains than penicillin-susceptible strains. Overall, antimicrobial resistance was higher among isolates from respiratory tract comparing with isolates from cerebrospinal fluid and blood. **Conclusions**: Resistance rates with *S. pneumoniae* have markedly increased in Romania during the last years. Pneumococcal isolates from Iaşi, Romania are often resistant to beta-lactams and available non-beta-lactam agents, especially if penicillin non-susceptible. **Key words**: *STREPTOCOCCUS PNEUMONIAE*, RESISTANCE, PENICILLIN

Streptococcus pneumoniae este cel mai important patogen al tractului respirator, care produce otite, sinuzite, bronşite şi pneumonie comunitară (1). În ultimele decade s-a remarcat creşterea concentraţiei minime inhibitorii (CMI) la penicilină (2); scăderea sensibilităţii la penicilină este însă diferită de rezistenţa la penicilină. Scăderea sensibilităţii la penicilină a apărut în toată lumea datorită diseminării mai multor clone rezistente la penicilină şi, în mai mică parte, datorită consumului excesiv de antibiotice (1).

Cu excepţia tulpinilor cu rezistenţă de nivel înalt, tratamentul bacteriemiei, sinuzitei, otitei, bronşitei sau pneumoniei comunitare produse de *S. pneumoniae* rezistent la penicilină rămâne penicilina sau orice alt beta-lactam. Doar pentru meningi-

ta pneumococică produsă de tulpini rezistente la penicilină clinicianul trebuie să aleagă un alt antibiotic, cu bună penetrabilitate în LCR şi rată de omorâre adecvată (1).

În ciuda creşterii ratei de rezistenţă a pneumococului la penicilină şi la macrolide în toată lumea, relevanţa clinică a acestui fenomen este încă necunoscută (3).

MATERIAL ŞI METODĂ

Tulpini bacteriene. Am inclus în studiu 155 tulpini non-duplicat de *S. pneumoniae* cu semnificaţie clinică de infectant, izolate din probe de spută, LCR sau hemocultură recoltate de la pacienţi internaţi în Spitalul de Boli Infecţioase „Sf. Parascheva" Iaşi în perioada 1.02.2003-31.12.2009 (tab. I). Izolatele au fost identificate ca *S. pneumoniae* prin caracterele de cultură pe agar-sânge şi testul de sensibilitate la optochin.

TABELUL I

Proveniența tulpinilor de *S. pneumoniae* incluse în studiu

	Spută	LCR	Hemocultură	Total
2003	4	7	1	12
2004	8	5	4	17
2005	12	20	5	37
2006	8	9	6	23
2007	9	12	4	25
2008	10	4	4	18
2009	12	7	4	23
Total	63	64	28	155

Testarea sensibilităţii la antibiotice. Pentru evaluarea sensibilităţii pneumococilor la antibiotice (eritromicină, E, clindamicină, CM, trimetoprim-sulfametoxazol, SXT, ofloxacin, OFX, levofloxacin, LVX, cloramfenicol, C, tetraciclină, TE, rifampicină, RIF, vancomicină, VA, linezolid, LZD) am utilizat metoda difuzimetrică pe agar Mueller Hinton cu 5% sânge de berbec (CLSI 2003-2008).

Pentru aprecierea sensibilităţii tulpinilor testate la penicilină (P) şi cefotaxim (CTX) am determinat CMI pentru aceste antibiotice folosind metoda diluţiilor în bulion Mueller Hinton cu concentraţie ajustată în cationi şi cu minim 2,5% sânge de cal lizat, conform recomandărilor CLSI, efectuată în duplicat (tulpini 2003-2007) şi metoda E-test (tulpini 2008-2009).

Controlul de calitate al testelor de sensibilitate la antibiotice a fost realizat folosind tulpina *S. pneumoniae* ATCC 49619.

Prelucrarea statistică. Baza de date şi prelucrarea datelor s-a realizat cu ajutorul programului EPIINFO 2005. Pentru compararea datelor s-a utilizat testul chi pătrat, fiind considerate semnificative valorile lui $p \leq 0,05$. Riscul relativ estimat Odds Ratio (OR) a fost calculat cu ajutorul intervalului de încredere IC95.

REZULTATE

Am analizat retrospectiv 155 tulpini non-duplicat de *S. pneumoniae* izolate între 2003-2009, cu un maxim de 37 tulpini izolate în 2005; 63 tulpini au fost izolate din probe de spută, 64 tulpini din LCR şi 28 tulpini din hemoculturi. Niciuna dintre tulpinile studiate nu a fost rezistentă la vancomicină sau linezolid. Rezistenţa la clindamicină, fluorochinolone, cloramfenicol, rifampicină a fost sub 10% (fig. 1).

Se observă o rată a tulpinilor non-sensibile (rezistente şi intermediare) la antibiotice mai mare pentru tulpinile izolate din probe respiratorii decât pentru cele izolate din produse normal sterile. Remarcăm în mod deosebit, prezenţa unui procent semnificativ mai mare de tulpini non-rezistente la cefotaxim (antibiotic de elecţie în tratamentul infecţiilor pneumococice invazive) în probe de spută comparativ cu celelalte produse patologice investigate. Peste 40% din pneumococii implicaţi în

infecții respiratorii joase au fost non-sensibili la penicilină, antibioticul de elecție în tratamentul acestor infecții. Majoritatea tulpinilor izolate din infecții pulmonare sunt rezistente la cotrimoxazol. Şi pentru eritromicină şi tetraciclină se observă rate înalte de rezistență între izolatele respiratorii de pneumococ (fig. 1).

Rezistența la penicilină a pneumococilor cauzatori de infecții respiratorii joase a avut o tendință continuu ascendentă, cu excepția anului 2009, când remarcăm scăderea bruscă, semnificativă ($p<0,05$) a procentului de tulpini rezistente (fig. 2).

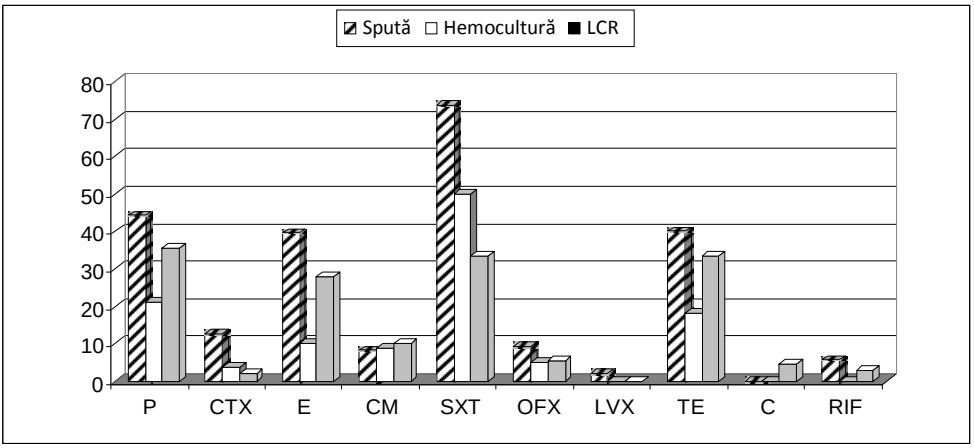

Fig. 1. Tulpini (%) de *S. pneumoniae* non-sensibile la antibiotice (2003-2009), în funcție de produsul patologic din care au fost izolate.

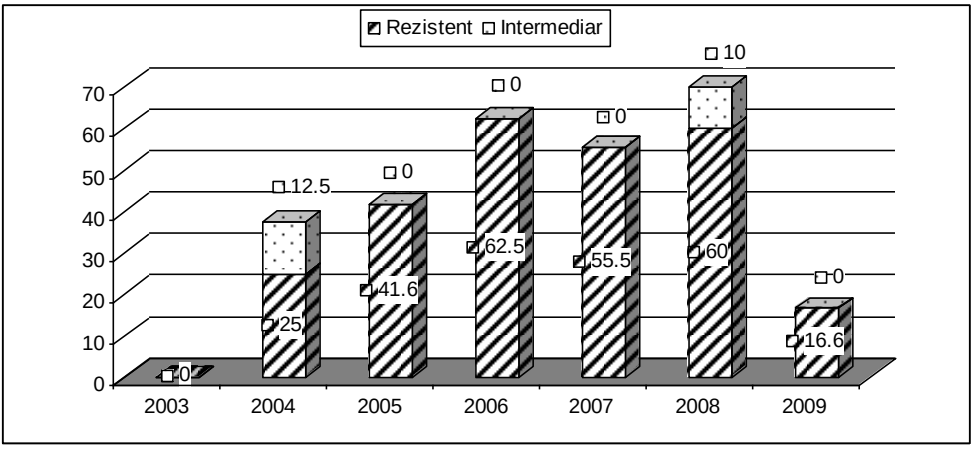

Fig. 2. Evoluția rezistenței la penicilină a pneumococilor izolați din probe de spută, 2003-2009.

Pentru penicilină şi cefotaxim am apreciat sensibilitatea la antibiotice prin determinarea CMI. Remarcăm că, în ciuda scăderii procentului de tulpini de pneumococ izolate din spută, rezistente la penicilină, în anul 2009, CMI_{90} pentru aceste tulpini s-a menținut la acelaşi nivel ca în anii precendenți (tab. II). Acest lucru este

explicat de modificarea punctelor de ruptură pentru penicilină în ianuarie 2008 (4, 5). Dacă am aplica punctele de ruptură CLSI 2008 şi tulpinilor anterioare acestei date, rata non-sensibilităţii pneumococilor izolaţi din infecţii respiratorii joase la penicilină ar fi diminuată. Tulpini de pneumococi rezistente la cefotaxim au fost izolate din probe de spută doar în 2007-2008.

În 2009 am izolat, de la un pacient cu meningită, o tulpină de *S. pneumoniae* rezistentă la penicilină şi cefotaxim, cu valori CMI foarte mari, >32 µg/ml pentru penicilină şi 16 µg/ml pentru cefotaxim.

TABELUL II

CMI_{50} şi CMI_{90} (µg/ml) pentru penicilină şi cefotaxim pentru izolate de *S. pneumoniae* din spută şi LCR

Din cele 155 tulpini testate, 22 (14,2%) au prezentat rezistenţă multiplă la antibiotice (i.e., rezistenţă la cel puţin 3 clase de antibiotice), cu un maxim de 38,9% tulpini în 2008. Dintre acestea, cele mai multe (14) au fost izolate din probe de spută (22,2%). Tot o tulpină izolată din infecţii respiratorii, în 2008, a fost rezistentă la 8 antibiotice. Cea mai frecventă combinaţie de rezistenţă multiplă la antibiotice a fost de penicilină, cotrimoxazol şi eritromicină.

DISCUŢII

Streptococcus pneumoniae a fost demonstrat a fi cea mai frecventă cauză a pneumoniei comunitare (PC) (6). La sfârşitul anilor 1970 au fost descrise tulpini de pneumococi rezistente la penicilină în Africa de Sud şi Spania. Până la începutul anilor 1990, clone rezistente la penicilină se răspândiseră rapid în Europa şi apoi în întreaga lume. În plus, în paralel cu rezistenţa la penicilină apăruse şi rezistenţa la macrolide şi alte antibiotice. Şase clone internaţionale (serotipurile 6A, 6B, 9V, 14, 19F, 23F) au fost responsabile pentru majoritatea acestor izolate rezistente. Actualmente, 20-30% din tulpinile de pneumococ din întreaga lume prezinta rezistenţă multiplă la antibiotice (7); aceste date sunt similare celor din studiul nostru.

Rezistenţa la antibiotice a pneumococului generează greutăţi în alegerea unui tratament empiric în pneumonie. În cazul tulpinilor cu rezistenţă intermediară la penicilină sunt recomandate doze crescute ale acestui antibiotic. Infecţiile cu tulpini cu rezistenţă de nivel înalt la penicilină trebuie tratate cu alte antibiotice, cum ar fi cefalosporine de generaţia a treia sau noile fluorochinolone antipneumococice. În ariile cu rezistenţă de nivel înalt la macrolide, cum este şi România, monoterapia empirică cu un macrolid nu este optimă pentru tratamentul pacienţilor spitalizaţi cu PC moderată sau moderat-severă. Fluorochinolo-

nele sunt considerate antibiotice excelente în tratamentul PC pneumococice la adult, dar recomandarea lor se face cu reținere pentru a evita dezvoltarea rezistenței (6).

A fost estimat că în anul 2004, în România au fost 10.000 cazuri de pneumonie pneumococică care au necesitat spitalizare şi 38.200 cazuri tratate în ambulatoriu. Costul total al acestor îngrijiri medicale a fost de 30 milioane RON, dintre care 86% au fost cheltuiți pentru cazurile spitalizate şi 14% pentru cele din ambulatoriu (8).

În România, rezistența la penicilină a pneumococilor izolați din probe de spută a crescut de la 33,3% în perioada 1973-1978 la 56,6% în perioada 1985-1989. Rezistența acestora la eritromicină a crescut de la 38,4% (1973-1978) la 66,6% (1979-1984). Din cele 83 de tulpini de pneumococi izolate din infecții umane între 1990-1995 1,2% au fost rezistenți la ceftriaxonă, 3,6% la cloramfenicol, 44,5% la cotrimoxazol (9). Între 2004-2005, tulpinile de *S. pneumoniae* izolate în Institutul "Marius Nasta" Bucureşti au fost în proporție de 13,4% cu rezistență înaltă la penicilină şi 39,3% cu rezistență de nivel jos la penicilină. Rata rezistenței la alte antibiotice a fost: 64,0% la cotrimoxazol, 18,8% la eritromicină, 8,3% la cloramfenicol. Toate tulpinile au fost sensibile la levofloxacin (10).

În studiul nostru, incidența tulpinilor de pneumococi izolați din probe de spută non-sensibili la penicilină, între 2003-2009 este mai redusă (41% rezistență de nivel înalt şi 3,2% rezistență de nivel jos) decât în studiile anterioare efectuate în România. Există discrepanțe mari privind rata rezistenței la eritromicină în studiile anterioare (66,6% *versus* 18,8%); în studiul nostru aceasta a fost de 39,6% în probe respiratorii. Remarcăm creşterea incidenței rezistenței la cotrimoxazol față de studiile anterioare, 71% rezistență a pneumococilor izolați din probe de spută.

Într-un studiu privind rezistența la antibiotice a *S. pneumoniae* din Sydney, Australia, Gosbell *et al.* (11) au ajuns la concluzia că rezistența la antibiotice non-beta-lactamice a fost mai frecventă la tulpinile rezistente sau intermediare la penicilină. Rezistența multiplă a fost găsită la 87% din tulpinile rezistente la penicilină. Rezistența la eritromicină a fost observată la 89% din tulpinile rezistente la penicilină. Unele izolate nu au fost sensibile la quinupristin/dalfopristin.

Într-un studiu efectuat pe 6991 tulpini de *S. pneumoniae* izolate în Canada între 1997-2002, 20,2% din tulpini nu au fost sensibile la penicilină. Proporția tulpinilor multidrog-rezistente a crescut de la 2,7% la 8,8% în cei 5 ani de studiu. În ciuda scăderii consumului de antibiotice în Canada în cei 5 ani, ratele rezistenței de nivel înalt şi a multirezistenței a *S. pneumoniae* au crescut (12).

În ciuda creşterii dramatice a ratei rezistenței la antibiotice la pneumococi, impactul clinic al rezistenței la antibiotice este greu de definit. Dezbaterile despre rolului rezistenței în creştere a pneumococului la beta-lactamine, macrolide şi fluorochinolone asupra ratei de eşec terapeutic continuă. Rezultatele *in vitro* nu par a fi predictive pentru rezultatele *in vivo* (3). Eşecurile clinice reflectă frecvent factori independenți de sensibilitatea la antibiotice a microorganismelor infectante. Factori care țin de gazdă (e.g., vârsta extremă, imunosupresia, boala de fond, comorbidități) sau factori care afectează virulența intrinsecă a microorganismelor (e.g., subtipul capsular) influențează puternic prognosticul. Rata mortalității este mai mare în prezența implicării multilobare, a insuficienței renale, a necesității de îngrijire în secția de terapie inten-

sivă, a hipoxemiei, dereglării severe a parametrilor fiziologici şi comorbidităţi (13).

CONCLUZII

Concentraţia minimă inhibitorie a penicilinei faţă de tulpini de *S. pneumoniae* izolate din probe de spută a avut o tendinţă crescătoare în perioada 2003-2008, în contrast cu CMI ale tulpinilor izolate din infecţii invazive, cu tendinţă stagnantă.

Nu am evidenţiat tulpini de *S. pneumoniae* rezistente la vancomicină sau linezolid, indiferent de sediul infecţiei.

Pneumococii izolaţii din infecţii în Spitalul Clinic de Boli Infecţioase „Sf. Parascheva" Iaşi sunt frecvent rezistenţi la antibiotice beta-lactamice, dar şi la alte antibiotice disponibile, mai ales dacă sunt tulpini non-sensibile la penicilină. Incidenţa tulpinilor de pneumococ cu rezistenţă multiplă la antibiotice este mai mare între izolatele din spută, cea mai frecventă asociere fiind penicilină-eritromicină-cotrimoxazol.

2. Facultatea de Biologie

HISTO-ANATOMICAL RESEARCHES OF TWO SUBSPECIES OF *LAVANDULA ANGUSTIFOLIA* MILL. (Abstract): **Aim:** The structure of the inflorescences of two subspecies of *Lavandula angustifolia* ş*L. angustifolia* ssp. *angustifolia* and. *L. angustifolia* ssp. *pyrenaica* (D.C.) Guineaţ was studied to determine the range of variation in certain histo-anatomical characters. **Methods**: The flower and leaf structure has been analysed on cross and superficial section using the usual techniques and methods applied in plant histo-anatomical research. **Results**: In cross-section, inflorescence axis has a squared-shape contour, with four proeminent ribs. On the epiderme of inflorescence axis there are present stomata, trichoms and secretory hairs. The trichoms are pluricelullar and T-branched. The secretory hairs have a short pedicel and a uni-or bicellular head. **Conclusions**: The study revealed that there are only quantitative differences, referring to the degree of sclerification and lignification of mechanical elements and the size of the vascular bundles. **Key words**: ANATOMY, INFLORESCENCES, *LAVANDULA ANGUSTIFOLIA*

Continuând investigaţiile noastre privind histo-anatomia şi compoziţia chimică a unor plante medicinale (1, 2), în studiul de faţă ne-am propus să comparăm structura anatomică a inflorescenţelor de *Lavandula angustifolia*.

În Flora Europaea (3) sunt descrise 7 specii de *Lavandula*, *Lavandula angustifolia* având 2 subspecii: *ssp. angustifolia* şi *ssp. pyrenaica* (D.C.) Guinea, care diferă între ele astfel:

- ssp. *angustifolia* prezintă bractei, de obicei, mai scurte decât caliciul, ce au o lungime de 4,5-6 mm, dintele mai înalt al caliciului fiind neclar;
- ssp. *pyrenaica* (D.C.) Guinea prezinta bractei, de obicei, mai înalte decât caliciul, ce au o lungime de 6-7 mm, dintele mai înalt al caliciului fiind vizibil.

Date sumare de ordin histo-anatomic referitoare la levănţică se întâlnesc în diferite lucrări, unele cu caracter de monografie (4, 5, 6, 7). De structura anatomică a unor clone de levănţică s-au ocupat la noi în ţară Toma şi Niţă (8), din al căror articol am preluat parte din descriere. După cum se ştie, inflorescenţa este spiciformă, lungă de 15-20 cm, alcătuită din dichazii scurt pedicelate dispuse în verticile ± spaţiate şi axilare, fiecare cu câte 4-6 flori aproape sesile (9). Florile au: **bractei ovate**, membranoase, lungi de 4-5 mm; **caliciu cilindric** (tubulos), lung de 4-5 mm, cu 10-15 nervuri paralele şi cu 5 dinţi (dintre care cel posterior este mai lung); **corolă tubuloasă**, zigomorfă, bilabiată, mai lungă decât caliciul, pubescentă şi glanduloasă; **androceu didinam**, cu cele 4 stamine având antere reniforme; **gineceu bicarpelar**,

cu stil ginobazic, stigmat bifid şi disc nectarifer tetralobat la baza ovarului.

Fructele sunt tetranucule (nucule ovoidale, lungi de 2 mm, cafenii), iar seminţele sunt exalbuminate.

MATERIAL ŞI METODĂ

Materialul vegetal inclus în studiu a fost constituit din inflorescenţe de *Lavandula angustifolia* ssp. *angustifolia* şi *Lavandula angustifolia* ssp. *pyrenaica* (D.C.) Guinea. Inflorescenţele au fost fixate şi conservate în etanol 70%, iar secţiunile prin axa inflorescenţei şi florii s-au realizat cu ajutorul unui microtom manual, fiind colorate cu verde de iod şi roşu de ruteniu şi incluse în gelatină glicerolată. Secţiunile permanente au fost analizate la un microscop Optika (WF 10X-18MM) prevăzut cu obiective (4x/0,1 ; 10x/0,25 ; 40x/0,65 ; 100 x/1,25 cu o cameră foto încorporată (Canon PSA 540, zoom optic 4x 6.0 megapixeli) şi program de prelucrare Optika Vision Lite 2007.

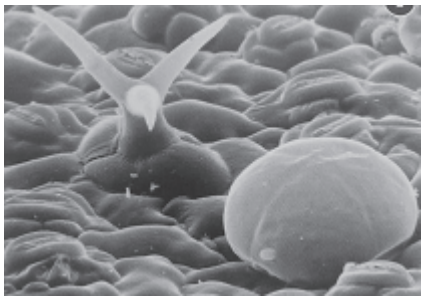

Fig. 6. Peri secretori şi tectori de la nivelul limbului foliar de *Lavandula angustifolia*

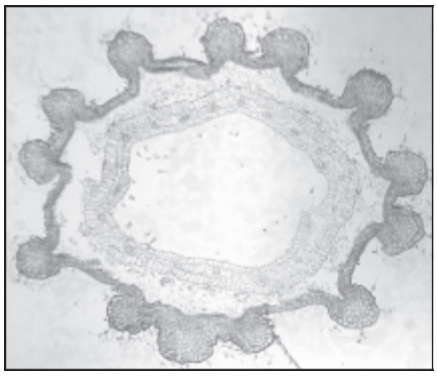

Fig. 7. Secţiune transversală prin floarea de *Lavandula angustifolia* ssp. *angustifolia :* caliciu şi corolă (imagine de ansamblu)

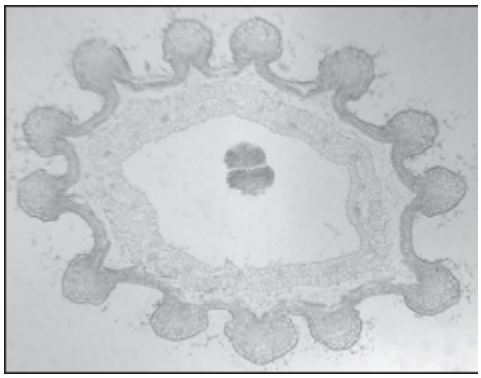

Fig. 8. Secţiune transversală prin floarea de *Lavandula angustifolia* ssp. *pyrenaica :* caliciu şi corolă (imagine de ansamblu)

REZULTATE ŞI DISCUŢII

Analizând particularităţile de structură ale axei pe care se inseră verticilele de flori, am constatat că axa inflorescenţei este prismatică, de contur pătratic în secţiune transversală, cu 4 coaste foarte proeminente; spre baza inflorescenţei, acestea alternează cu altele mai puţin proeminente (fig. 1, 2).

La nivelul epidermei axei inflorescenţei se disting stomate, peri tectori şi peri secretori. Atât frecvenţa perilor secretori, cât şi a celor tectori scade de la vârful către baza inflorescenţei. Perii glandulari, secretori au celula bazală mai mică decât celulele epidermice care o înconjoară, constituind pedicelul unicelular pe care se găseşte glanda uni- sau bicelulară. Perii tectori, aproape totdeauna pluricelulari şi ramificaţi în formă de T, sunt morţi la maturitate, plini de aer şi formează un toment albicios cu rol în protecţia plantei împotriva unei transpiraţii excesive.

Valoarea inflorescenţelor este dată de uleiul volatil sintetizat de perii glandulari secretori (fig. 3, 4), dar şi de papilele epidermice ale petalelor. Perii secretori se găsesc în tot lungul tulpinii, pe toate frunzele (fig. 5, 6), pe axul inflorescenţei şi pe flori.

Pe lângă perii secretori, perii tectori, ramificaţi sunt evidenţi atât pe axa inflorescenţei, cât şi pe caliciu şi corolă.

În ceea ce priveşte structura florii (fig. 7, 8, 9, 10), periantul interesează cel mai mult prin numărul mare de peri secretori (alături de peri tectori) care se află pe caliciu şi corolă şi în care se acumulează uleiul volatil. Perii secretori sunt predominant cu glanda uni- sau bicelulară, şi doar rar octocelulari, caracteristici labiatelor.

La nivelul inserţiei staminelor, tubul corolei are două inele de peri, unii tectori şi

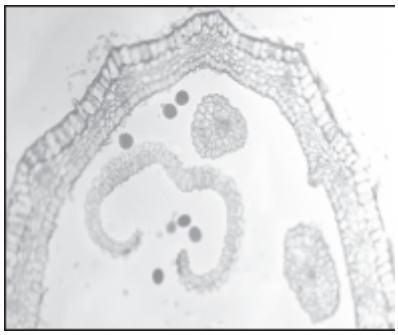

Fig. 9. Secţiune transversală prin floarea de *Lavandula angustifolia* ssp. *angustifolia :* corolă şi stamine

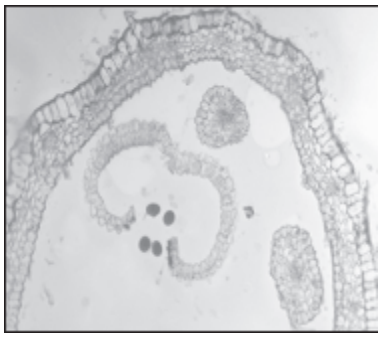

Fig. 10. Secţiune transversală prin floarea de *Lavandula angustifolia* ssp. *pyrenaica :* corolă şi stamine

alţii secretori, cu pedicel relativ lung (bi-sau tricelular) şi cu glanda măciucată, uni-sau bicelulară. Numărul perilor tectori şi secretori de pe caliciu şi corolă este mai mare la ssp. *pyrenaica* decât la ssp. *angustifolia*.

CONCLUZII

Studiul histo-anatomic a scos în evidenţă faptul că structura inflorescenţelor celor două subspecii investigate este similară cu cea a speciei originare *Lavandula angustifolia*, diferenţele la nivelul axei inflorescenţei fiind doar de ordin cantitativ şi se referă la gradul de sclerificare şi de lignificare a elementelor mecanice, mărimea fasciculelor conducătoare, grosimea cordoanelor de fibre perifloemice.

La nivelul florii, se observă caliciul cu coaste (nervuri) proeminente, corola cu celule epidermice de mărime diferită pe cele 2 feţe ale petalelor, gineceul cu 2 carpele unite, stil şi stigmat uşor bifid, precum şi androceul cu cele 4 antere (de contur circular fiecare în stadiu tânăr, cu şanţ ventral ce separă cele 2 loje în stadiul de maturitate deplină, înainte de deschiderea şi eliberarea granulelor de polen).

Deosebirile de structură între cele 2 subspecii sunt mici şi doar de ordin cantitativ. *Lavandula angustifolia* ssp. *pyrenaica* are :

- nervurile (coastele) caliciului mai puţin proeminente decât ale ssp. *angustifolia* ;
- corola cu petale mai subţiri, celulele ambelor epiderme fiind mult mai mari în comparaţie cu cele ale mezofilului ;
- numărul perilor tectori şi secretori de pe caliciu şi corolă, mai mare.

STUDIU COMPARATIV PRIVIND STAREA DE SĂNĂTATE PARODONTALĂ PRIN PRISMA INDICILOR DE PLACĂ ŞI GINGIVALI

Carina Balcoş, I. Dănilă, Cătălina Iulia Săveanu
Universitatea de Medicină şi Farmacie "Gr.T.Popa" Iaşi
Facultatea de Medicină Dentară
Disciplina de Prevenţie Oro-Dentară

COMPARATIVE STUDY ON THE PERIODONTAL HEALTH STATUS TROUGH PLAQUE AND GINGIVAL INDEX (Abstract): Nowadays, people are becoming more aware of the importance of oral hygiene in maintaining the health of the entire body. It is well known that plaque is the main etiological factor in producing caries disease and periodontal disease. The purpose of this study was to evaluate the comparative value indices of plaque and gingival inflammation in a group of young adults. **Material and method**: The study was conducted on a sample of 254 subjects. The study was clinical type. Data were collected after completion revelation plaque and clinical examination recorded the values calculated for each index in the observation sheet. The clinical evaluation of oral health status we used the API index (approximated Plaque Index) and BI indices for assessing periodontal status (bleeding index). All subjects included in the study were informed verbally about the purpose of the study noting the consent form. Patients were included in the database according to certain codes. Statistical data processing was done with the program for Windows SPSS14.00 setting a threshold of statistical significance of $p = 0.05$. **Results**: Comparative analysis of the presence of plaque and degree of gingival inflammation has revealed that there are differences statistically significant $p \leq 0.05$ for having a valoatre API index averaged 72.71 ($\pm$ 23.48) compared with gingival index = BI has an average of 20.05 ($\pm$ 18.32) and that influences the use of dental wire index periodontal inflammation. **Conclusions**: Gingival inflammation is present in those with plaque and is subject to use wire but not the frequency of tooth brushing which demonstrates that the use of adjuvant means brushing helps remove plaque but not entirely.
Key words: API, BI, GINGIVAL INDEX, YOUNG ADULTS

În prezent, populaţia este din ce în ce mai conştientă de importanţa igienei orale în menţinerea stării de sănătate a întregului organism. Este bine cunoscut, faptul că, placa bacteriană este factorul etiologic principal în producerea bolii carioase şi a afecţiunilor parodontale. Apariţia fenomenelor inflamatorii parodontale se observă cu predilecţie la nivelul spaţiilor aproximale, acolo unde îndepărtarea plăcii bacteriene se realizează cu dificultate. Astfel s-a introdus în practică cuantificarea plăcii bacteriene prin indicele API (Aproximal Plaque Index - Lange, 1981). Indicele de sângerare gingivală (BI – bleeding index) este un indice corelat cu API, care apreciază sângerarea la nivelul spaţiilor aproximale. Astfel se poate realiza corelarea dintre maturarea plăcii bacteriene de la nivelul situsurilor proximale şi fenomenele inflamatorii de la acest nivel.

Scopul acestui studiu a fost evaluarea comparativă a valorii indicilor de placă bacteriană şi a celor de inflamaţie gingivală la un lot de tineri.

MATERIAL ŞI METODĂ

În conceperea şi derularea studiului clinic s-a formulat ipoteza nulă că nu există diferenţe semnificative din punct de vedere statistic între prezenţa cantitativă şi calitativă a plăcii bacteriene pusă în evidenţă prin indicele API şi inflamaţia parodontală cuantificată cu ajutorul indicelui BI. Ipoteza testabilă constă în faptul că există diferenţe din punct de vedere statistic între valorile indicilor care cuantifică placa bacteriană şivalorile indicilor care cuantifică gradul de inflamaţie gingivală.

Studiul a fost realizat pe un lot de 122 de subiecţi, studenţi ai anului III, Facultatea de Medicină Dentară, UMF Gr.T.Popa Iaşi. Lotul a fost format din 78 de subiecţi de sex feminin şi 45 subiecţi de sex masculin, cu o medie de vârstă de 23,53 ani (vârste între 21-29 ani).

Criteriile de includere a subiecţilor au fost : prezenţa plăcii bacteriene după revelare, consimţământul pacienţilor de a participa la studiu. Criteriile de excludere au fost reprezentate de absenţa plăcii bacteriene, refuzul pacienţilor de a participa la studiu. Studiul a fost de tip clinic.

Datele au fost colectate în urma realizării revelării plăcii bacteriene şia examenului clinic consemnând valorile calculate pentru fiecare indice în fişa de observaţie. Pentru evaluarea clinică a stării de igienă orală am utilizat indicele API (Aproximal Plaque Index) iar pentru evaluarea statusului parodontal indicii BI (bleeding index).

Pentru determinarea prezenţei plăcii bacteriene în spaţiile aproximale prin indicele API s-a realizat revelarea plăcii bacteriene cu albastru de metil. API apreciază procentual acumularea plăcii bacteriene în spaţiile aproximale. Formula de calcul este : numărul de spaţii aproximale cu placă raportat la numărul de spaţii aproximale de înmulţit cu 100. Aprecierea stării de igienă orală în funcţie de valoarea API se face după următoarea scală de valori : API = 100-70% - igienă total nesatisfăcătoare ; API = 70-35% - igienă orală medie ; API = 35-25% - igienă orală relativ corectă ; API < 25% = igienă orală optimă.

Evaluarea statusului parodontal s-a realizat prin utilizarea indicelui gingival BI (Bleeding Index) care este definit astfel : 0- gingie fără sângerare la sondaj ; 1- sângerare la sondaj.

Indicele BI se determină cu ajutorul unei sonde parodontale, care se introduce la baza papilei, mezial şi distal, în unghi de 20-40^0 faţă de axul dintelui până la baza şanţului gingival. Scorurile utilizate pentru determinare sunt : 0- gingie fără sângerare la sondaj ; 1- sângerare la sondaj. BI se calculează împărţind suma valorilor înregistrate la numărul de papile interdentare examinate de înmulţit cu 100.

Toţi subiecţii incluşi în studiu au fost informaţi verbal cu privire la scopul studiului notându-se în fişă consimţământul acestora. Examinarea pacienţilor s-a realizat în cabinetul Policlinicii nr.1, Ambulatorul de Stomatologie. Pacienţii au fost introduşi în baza de date conform anumitor coduri.

Prelucrarea datelor statistice s-a realizat cu programul SPSS14.00 pentru Windows stabilindu-se un prag de semnificaţie statistică de $p \leq 0,05$.

REZULTATE ŞI DISCUŢII

Rezultatele analizei comparative a prezenţei plăcii bacteriene şia gradului de inflamaţie gingivală au pus în evidenţă faptul că există diferenţe semnificative din punct de vedere statistic $p \leq 0,05$ în favoarea indicelui API care are o valoatre medie de 72,71 ($\pm$23.48) în comparaţie cu indicile gingival BI care are o valoare medie de 20,05 ($\pm$ 18.32) (tabel I).

Din punct de vedere al corelaţiilor între acesti indici, analiza Pearson a datelor evidenţiază corelaţii între indicii API şi BI ($p \leq 0.05$) rezultate care susţin ipoteza acţiunii plăcii bacteriene asupra ţesutului gingival

TABELUL I

Pair 1	API – BI	52,65787	26,00298	2,35420	47,99711	57,31863	22,368	121	,000

din spaţiile aproximale (tabel. II) manifestată prin modificare de aspect şitextură a gingiei dar şiprin apariţia sângerăriii la sondajul parodontal.

Analiza statistică realizată a permis identificarea unor diferenţe semnificative între nivelul mediei indicelui de placă bacteriană API şiindicele de inflamaţie parodontală BI; testul $t(121)=22,36$ pentru $p<0,001$ argumentând acest lucru (tabel III,IV,V). Astfel placa bacteriană este prezentă în mai multe cazuri decât inflamaţia gingivală tradusă prin sângerare ceea ce indică că la unii pacienţi placa bacteriană este nepatogenă în sensul afectării parodontale şi nevirulentă.

Corelarea prezenţei plăcii bacteriene în spaţiul aproximal cu utilizarea firului dentar indică că nu există diferenţă semnificativă între valorile API la cei care utilizează fir interdentar şi cei care nu utilizează (tabel VI).

În schimb la subiectii care utilizează fir interdentar nu apare inflamaţie gingivală $p\leq0,001$ (tabel VIII,IX). Acest lucru ne orientează asupra faptului că analiza printr-un indice calitativ de placă bacteriană care pune în evidenţă dacă este sau placă bacteriană nu ne dă întotdeauna rezultatele cele mai concludente.

Nu există diferenţe semnificative din punct de vedere statistic între frecvenţa periajului şi valoarea indicilor API şi SBI (X,XI) valorile fiind medii pentru cei care realizează periaj o dată pe zi şi pentru cei care realizează periaj de două ori pe zi.

CONCLUZII

Inflamatia gingivală este prezentă la cei care prezintă placă bacteriană şi este condiţionată de utilizarea firului dentar dar nu şide frecvenţa periajului ceea ce demonstrează că utilizarea mijloacelor adjuvante periajului dentar ajută la îndepărtarea plăcii bacteriene dar nu în totalitate. Deoarece nu toţi pacienţii care prezintă placă bacteriană în spaţiul aproximal prezintă şiinflamaţie gingivală se sugerează că în etiologia afectării parodonţiunui marginal este prezent şiun factor general care influenţează răspunsul imun local.

RESEARCH ON THE INCIDENCE AND PREVALENCE OF CONGENITAL ABNORMALITIES IN IAŞI DISTRICT AND IAŞI CITY, FROM 2001 TO 2008 (Abstract): Congenital abnormalities (CA) are deviations from the normal embryonic development that appear antenatal and they are characterized by the alteration of the morphology and function of an organ, system of organs or even of the entire body. **Material and method**: The study, on a period of eight years, included 1685 children with CA, from which 58% were males and 50% were from the country-side. **Results**: It has been observed that 36% of the CA cases were premature births and 64% were normal term births. Also, 21% of the children with CA weighed less than 2700 grams at birth and 79% weighed more than 2700 grams at birth. The birth's APGAR score has been less than 7 in 30% of the cases and higher than 7 in 70% of the cases. 72% of the cases were natural births and 28% were caesarian births. 88% of the CA cases were singular congenital abnormalities and 12% were multiple congenital abnormalities. 24% of the CA were cardiac abnormalities and 21% were skeletal abnormalities. 3% of the subjects of the study have died, of which 69% died from cardiac abnormalities, 22% from hydrocephalus abnormalities, 7% from diaphragmatic hernia and 2% from renal congenital abnormalities. **Key words**: CONGENITAL ABNORMALITIES, PREVALENCE, EPIDEMIOLOGIC SURVELANCE, PREVENTION

Eficienţa redusă a metodelor de screening pentru depistarea precoce şi a unor programe terapeutice care să reducă impactul, de multe ori dezastruos, asupra bolnavului, familiei şi societăţii, situează anomaliile congenitale (AC) între maladiile care determină grave implicaţii sociale şi economice (4). Cercetările epidemiologice colaborative, multidisciplinare, realizate pe loturi reprezentative de bolnavi şi perioade multianuale, aduc informaţii valoroase pentru orientarea programelor de supraveghere epidemiologică, clinică şi de laborator a grupurilor cu risc şi a copiilor cu AC.

Datele cercetărilor noastre de factură clinico-epidemiologică pot constitui o contribuţie în direcţia ameliorării eficienţei prevenţional-terapeutice a asistenţei pentru pacienţii cu AC.

Prin anomalie congenitală se înţelege un defect morfologic, structural (macroscopic sau microscopic) al unui organ sau regiune anatomică, prezent la naştere, chiar dacă nu este evident la momentul ontogenetic

respectiv (1,5,7,8).

Din punct de vedere patogenic, anomaliile congenitale se împart în: malformaţii, disrupţii, deformaţii şi displazii. În raport cu manifestările clinice, anomaliile congenitale pot fi izolate şi multiple. Aceste două clasificări ale anomaliilor congenitale sunt cele mai folosite în practica medicală, deoarece permit stabilirea prognosticului, a conduitei practice şi, nu în ultimul rând, a riscului de recurenţă al afecţiunii (2,3,6).

MATERIAL ŞI METODE

Cercetările au inclus 1685 de copii diagnosticaţi cu AC în perioada 2001-2008, reprezentând o prevalenţă de 3,3% din totalul naşterilor raportate în Spitalul Clinic de Obstetrică şi Ginecologie "Cuza Vodă", Iaşi.

Culegerea informaţiilor s-a realizat prin colaborarea cu serviciile de statistică medicală ale clinicii şi prin studierea registrelor de evidenţă a copiilor cu AC, din cadrul secţiei de neonatologie. Au fost analizate cazurile înregistrate pe parcursul fiecăruia dintre cei 8 ani, în corelaţie cu sexul, mediul de provenienţă (rural, urban), felul naşterii (naturală, cezariană), greutatea la naştere (<2700 g, >2700 g), vârsta gestaţională (<37 săptămâni, >37 săptămâni) şi scorul APGAR (<7, >7).

Prelucrarea şi interpretarea datelor acumulate a fost realizată prin metode epidemiologice, statistico-matematice şi computerizate.

În realizarea diferitelor etape ale programului de cercetare au fost respectate: colaborarea etică cu ceilalţi medici implicaţi în managementul acestor cazuri, adoptarea unei atitudini nediscriminatorii, fără a emite judecăţi lipsite de profesionalism, confidenţialitatea actelor medicale şi a datelor personale, cu excepţia datelor statistice incluse în studiu.

REZULTATE ŞI DISCUŢII

1. Repartiţia pe sex şi mediul de provenienţă a 1685 de copii diagnosticaţi cu AC în secţia de neonatologie a Spitalul Clinic de Obstetrică şi Ginecologie "Cuza Vodă" Iaşi, în perioada 2001-2008. În cei 8 ani luaţi în studiu, din lotul de 1685 de copii cu AC, 710 (42%) au fost de sex feminin, 975 (58%) masculin; 843 (50%) au provenit din mediul urban şi 842 (50%) din rural.

S-a observat o afectare preponderentă a sexului masculin faţă de feminin ($p \leq 0,05$), fără diferenţe semnificative între rural şi

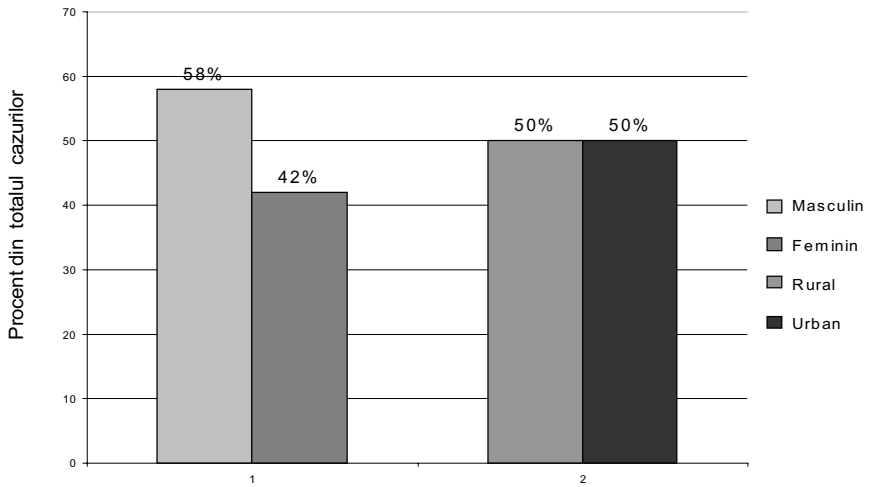

Fig. 1. Repartiţia pe sex şi mediul de provenienţă a cazurilor de anomalii congenitale, raportate la Spitalul Clinic de Obstetrică şi Ginecologie "Cuza Vodă", Iaşi, în perioada 2001-2008

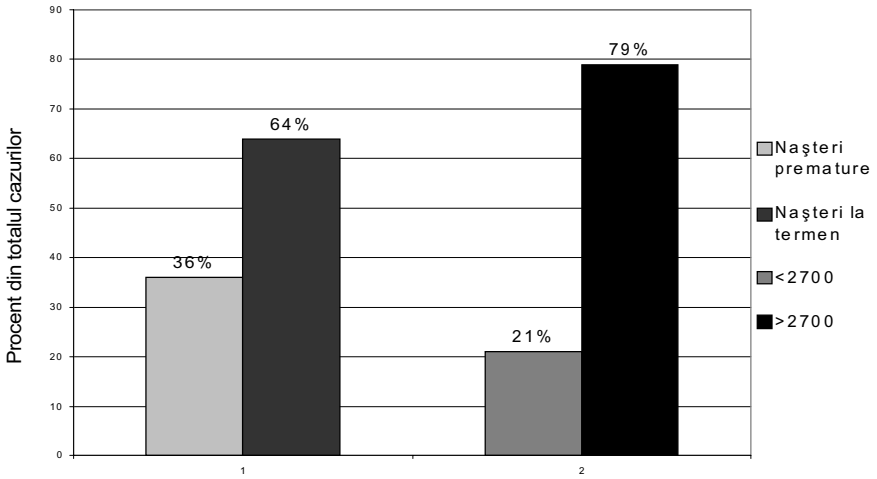

Fig. 2. Valorile prevalenţei cazurilor de anomaliilor congenitale, în raport cu vârsta gestaţională şi greutatea la naştere, raportate la Spitalul Clinic de Obstetrică şi Ginecologie "Cuza Vodă", Iaşi, în perioada 2001-2008

urban (p≥0,05). Estomparea diferenţei între mediul urban şi cel rural poate fi urmarea modificărilor care au loc între cele două medii, îndeosebi prin migrarea, în ultimele 3-4 decenii, din mediul rural spre cel urban, a unor importante categorii demografice. Acest fenomen a determinat un amestec şi o asociere puternică a unor factori care în mediul urban ar putea fi consideraţi cu risc pentru apariţia AC (fig.1).

2. Analiza repartiţiei, în relaţie cu vârsta gestaţională şi greutatea la naştere. În perioada luată în studiu, din cele 1685 de cazuri de AC înregistrate, 603 (36%) au provenit din sarcini care s-au încheiat prematur (înainte de 37 de săptămâni) iar restul de 1082 (64%) s-au născut la termen (depăşind 37 de săptămâni de sarcină). De asemenea, 351 (20%) de copii au avut o greutate la naştere mai mică de 2700 grame şi 1334 (80%) de copii au avut peste 2700 grame la naştere. Studiul asupra greutăţii înregistrate la naştere a evidenţiat pentu copiii cu greutate mică (<2700 grame) diferenţe anuale ale prevalenţei (9% în 2005 şi 41% în 2008)($p \leq 0,05$), comparativ cu cei cu greutate normală (91% în 2005 şi 59% în 2008)($p < 0,005$). În ceilalţi ani, diferenţele nu au avut o semnificaţie deosebită (fig. 2).

3. Repartiţia în relaţie cu felul naşterii şi scorul APGAR acordat la naştere. În perioada de 8 ani ce a făcut obiectul studiului, s-a constatat că prevalenţa suferinţei fetale (scor APGAR < 7) în rândul copiilor cu AC variază între 15% (în anul 2002) şi 34% (în anii 2004 şi 2008).

S-a mai constatat că prevalenţa naşterilor naturale, în cazul copiilor cu AC, variază între 59% (în anul 2004) şi 97% (în anul 2002), în timp ce prevalenţa naşterilor prin cezariană variază între 3% (în anul 2002) şi 41% (în 2004) (tab. I).

4. Distribuţia cazurilor în relaţie cu caracterul izolat sau multiplu, al prezenţei anomaliilor congenitale. Anomalii izolate s-au înregistrat la 88% din cazuri, cele mai frecvente fiind cele cardiace (24%) şi scheletice (21%)(tab. II).

Anomalii congenitale multiple. Prezenţa asocierii unor anomalii diferite la acelaşi caz s-a înregistrat într-un număr semnificativ scăzut ($p \leq 0,05$) faţă de cele izolate. În cei 8 ani de studiu au fost observate 196 de cazuri cu AC multiple (12% din totalul

TABELUL I

2007	31	14	45	0	0	5	16	12	39
2008	24	6	25	3	13	6	25	9	37

(*) Pentru valorile mai mici de 10, proporţiile sunt orientative

cazurilor de AC). Dintre acestea, ponderea cea mai mare au avut-o cazurile de asociere a 2 anomalii (35%), urmate de cazurile de asociere a 4 anomalii (17%) şi cazurile de asociere a 3 anomalii (13%). Dintre sindroamele plurimalformative cel mai frecvent întâlnit a fost sindromul Down, determinat de trisomia 21 şi care se caracterizează printr-un model caracteristic de dezvoltare anormală (tab. III).

5. Decesele înregistrate la copiii cu anomalii congenitale. În perioada 2001-2008, au decedat 45 de copii (3%) din totalul de 1685 de cazuri cu AC. Dintre aceştia, 69% prezentau anomalii cardiace, 22% hidrocefalie, 7% hernie diafragmatică şi 2% anomalii renale.

CONCLUZII

Anomaliile congenitale (AC) reprezintă o cauză importantă a numeroase implicaţii nefavorabile, medicale şi socio-economice la nivel mondial.

Studiul, pe durata a 8 ani, a inclus 1685 de copii cu AC, dintre care 58% de sex masculin şi 42% de sex feminin. Proporţiile au fost egale pentru mediile urban şi rural. S-a evidenţiat o prevalenţă de 36% pentru naşterile premature şi 64% pentru naşterile la termen. 21% dintre copii au avut o greutate la naştere < 2700 grame şi 79% > 2700 grame. 30% dintre subiecţii luaţi în studiu au prezentat suferinţă fetală (scor APGAR < 7). În funcţie de caracterul naşterii, majoritatea (72%) au fost înregistrate naşteri naturale. Anomaliile congenitale izolate au reprezentat 88% şi cele multiple 12%. 24% dintre anomalii au fost de natură cardiacă, în timp ce 21% au fost de natură scheletică. 3% din numărul de copii diagnosticaţi cu AC au decedat, 69% dintre aceştia suferind de anomalii cardiace, 22% hidrocefalie, 7% hernie diafragmatică şi 2% anomalii congenitale renale.

EPIDEMIOLOGICAL ASPECTS OF FRONTAL EDENTATION OF CHILD AND ADOLESCENT (Abstract): Increasingly frequency of frontal edentation of children and adolescents, mainly because of dental caries and its complications and other diseases requires closer analysis and a reconsideration of therapeutic attitudes that must be carefully adapted and refined. **Aim**: To study the establishment of prevalence and incidence of child and adolescent frontal edentation, identifying its etiology and prospects of restoration of morpho-functional parameters affected, anchored in temporary or permanent solutions, according to age and morpho-functional development of the patient. **Material and methods**: We studied a group composed of 450 patients, aged between 8 and 19 years of age, diagnosed with frontal edentation of different etiologies. **Results**: The two most common causes which are involved in producing edentation are odontal injuries and chronic periodontal disease. **Conclusion**: Etiology of frontal edentation has an esential part in the anatomoclinical shape of edentation, without evading the impact on bio-psycho-social dimension of this clinical entity. The size of the edentation, the emotional impact for the child, and the medical aspects are very important in the decision of the right treatment for long time. **Key words**: ADOLESCENT, CHILD, FRONTAL EDENTATION, STATISTIC

IN VITRO DISSOLUTION STUDIES OF AMIODARONE HYDROCHLORIDE FROM HYDROXY-PROPYL-β-CYCLODEXTRIN/AMIODARONE INCLUSION COMPLEX FORMULATED INTO MODIFIED-RELEASE TABLETS

IN VITRO DISSOLUTION STUDIES OF AMIODARONE HYDROCHLORIDE FROM HYDROXY-PROPYL-β-CYCLODEXTRIN/AMIODARONE INCLUSION COMPLEX FORMULATED INTO MODIFIED-RELEASE TABLETS (Abstract) **Aim:** Drug release from modified-release matrix tablets made of Kollidon® SR and Chitosan is dependent on its degree of solubility in the dissolution medium as well as on the matrix forming polymer. By complexing hydrochloride amiodarone with hydroxypropyl-β-cyclodextrin, an inclusion complex was obtained, which showed an increase in solubility by more than 200%. The complex was used to obtain modified-release matrix tablets based on Kollidon® SR and Chitosan. **Materials and Methods**: Matrix tablets were obtained through direct compression method of non-complexed amiodarone and inclusion complex, and they were marked F1 and F10, respectively. The two formulations were studied comparatively in terms of release kinetics of the active substance through in vitro drug release tests. Those tests were conducted using a paddle apparatus II for 12 hours and two gastrointestinal simulation liquids with different pH values relevant for oral administration - 2 hours at pH 1.2 and 10 hours at pH 6.8. The release of hydrochloride amiodarone was quantified using a validated HPLC method. Two factors were calculated to assess the release profile of amiodarone: the similarity factor f1 and difference factor f2. **Results:** The increase in Kollidon® SR concentration resulted in a slower release of amiodarone at both pH values. The use of Chitosan resulted in a decrease of AMD release only at pH 6.8. **Conclusions:** The similarities between the two release profiles of AMD were confirmed by the values of the similarity factor (f1 = 43.697) and difference factor f2 (f2 = 68.263). **Keywords:** AMIODARONE, INCLUSION COMPLEXE, MATRIX TABLETS, SUSTAINED RELEASE, KOLLIDON® SR, CHITOSAN.

Amiodarone [2-butyl-3-(3,5-diiodo-4-β-diethylaminoetoxybenzoyl)benzofuran] (AMD) originally used as an antianginal, is currently administered as cardiovascular medication in the treatment of severe supraventricular and ventricular arrhythmias (1). AMD is a Class III antiarrhythmic substance which prolongs the duration of action potential and effective refractory period in both the atria and ventricles. The absorption of

amiodarone in the gastro-intestinal tract is variable and hard to predict. The oral bioavailability ranges from 22% to 86%. Large individual variations were attributed to the dealkylation of the molecule to its primary metabolite desethylamiodarone (2,3). This unpredictable absorption may be explained by the low solubility of amiodarone in aqueous solutions and by the hepatic first-pass effect, which has been not clearly defined (4).

In terms of pharmacokinetics, amiodarone is included in the II BCS class (biopharmaceutical classification system), as it is characterized by increased membrane permeability and a low rate of dissolution, due to the low solubility in water (5). The formulation of AMD-based polymer matrix tablets can alter the dissolution rate and oral bioavailability of this active substance.

Currently, AMD is used in therapy as conventional release pharmaceutical products - 200 mg AMD oral tablets, under the trade name Cordarone®.

The aim of this study was to improve the biopharmaceutical properties of AMD by various pharmacotechnical methods. In the first stage AMD was included in hydroxypropyl-β-cyclodextrin (HP-β-CD) which resulted in the HP-β-CD/AMD inclusion complex that has been physicochemical and pharmacokinetic characterized (6-9).

In the second phase modified release matrix tablets were formulated based on Kollidon® SR (KOL) and Chitosan (CHT) in which AMD was used as non-complexed active substance and as HP-β-CD/AMD inclusion complex. Two matrix tablet formulations were comparatively studied in terms of AMD release profile.

MATERIAL AND METHODS

The raw materials used were 100.2% pure Amiodarone hydrochloride (Zhejlang Sanmen Hengkang Pharmaceutical Co. Ltd., China,), Kollidon® SR and practical grade Chitosan (BASF, Germania), Aerosil 200 (Degussa, Germania) and Magnesium stearate (Union Derivan S.A., Spania), and HP-β-CD/AMD inclusion complex ("Petru Poni" Institute of Macromolecular Chemistry Iaşi, România).

The preparation of matrix tablets: In a previous study we analyzed the concentration of polymer matrix for tablets with optimal technical and pharmacokinetic properties. Based on the results of that study two formulations of AMD modified-release matrix tablets were formulated and their pharmaceutical formulation is presented in Table I. AMD matrix tablets were obtained by direct compression method using a Korsh EK0 machine with 9 mm ponson diameter and 8-10kN compression force.

TABLE I
Formulation of matrix tablets

Matrix components (% w/w)	Formula	
	F1	F10
AMD·HCl	33.33	-
HP-β-CD/AMD	-	33.33
KOL	40	40
CHT	3	3
Aerosil	1	1
Magnesium stearate	0.5	0.5
Avicel	up to 100%	

In vitro dissolution studies were performed according to the specifications of "Dissolution test for solid pharmaceutical forms" monograph of the European Pharmacopoeia 8th Ed. (10) according to the following experimental protocol: pH 1.2 dissolution medium (0.1N HCl solution) for the first 2 hours (simulation medium for gastric fluids) and pH 6.8 dissolution medium (phosphate buffer) for the next 10 hours (simulation medium for intestinal fluids); SR 8 Plus Series II Apparatus with

paddle (ABL&E-JASCO); 37±0.5°C bath temperature; 50 rpm rotation speed. Sampling interval was set to every hour during the 12 hours of the test (7 mL of sample were replaced at each harvest with the same volume of medium).

AMD quantitative determination was performed by high performance liquid chromatography (HPLC), using an octyldodeculsilyl solid phase and a 0.5% formic acid and methanol mixture as mobile phase in a 25:75 ratio. The temperature of the column was 45±0.2°C. The HPLC method has been validated (11).

The tests were carried out on three tablets, and the results are the mean of determinations.

Analysis of difference factor f1 and similarity factor f2: According to pharmacotechnical specifications for the preparation of modified release tablets, the release profile of the active substance in that type of tablet was analyzed by determining the difference factor f1 and similarity factor f2 between two or more formulations.

These two factors for assessing the AMD release profile from the studied formulations were calculated according to the following equations:

$$f_1 = \left\{ \frac{\sum_{t=1}^{n} |R_t - T_t|}{\sum_{t=1}^{n} R_t} \right\} \times 100$$

$$f_2 = 50 \log_{10} \left\{ \left[1 + \frac{1}{n} \sum_{t=1}^{n} (R_t - T_t)^2 \right]^{-0.5} \times 100 \right\}$$

where: n = the number of samplings, R_t = the amount of dissolved drug substance of reference formula at t moment, T_t = the amount of dissolved drug substance of tested formula at t moment.

RESULTS AND DISCUSSION

The results showed that the two tablet formulations achieved a sustained AMD release. It was noted that F10 formula containing HP-β-CD/AMD inclusion complex generated a faster release of AMD compared to F1, but the release kinetic profile did not change. This finding was consistent with the results of previous studies which had shown that the solubility of AMD had increased considerably by complexation with HP-β-CD (7,12).

The studied formulations achieved a prolonged release of AMD for 6 to 8 hours. Within six hours F1 formula has released 80.95% of AMD while F10 formula 86.59% of the active substance (fig. 1).

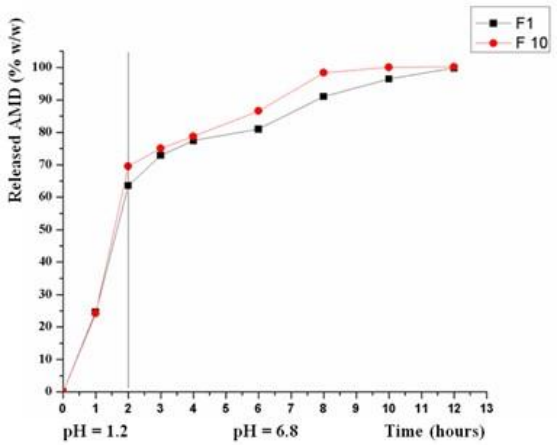

Fig. 1. The *in vitro* dissolution profile of AMD·HCl from F1 and F10

The influence of matrix forming agents on the release of AMD from the inclusion complex formulated as modified-release tablets was confirmed by the values of f1 and f2 factors shown in tab. II.

TABLE II

Values of difference and similarity factors for F1 and F10 formulations

Reference formulation F1	Determined factor	F10
	f1	43.697
	f2	68.263

The results obtained in that step revealed that the two formulations were the same in terms of the release profile of the active substance. It appeared that improving the solubility of AMD in the HP-β-CD/AMD inclusion complex was reflected to a lesser extent in AMD release. Thus, we believe that AMD release from modified-release tablets based on KOL and CHT is controlled only by those two matrix formers and that the low solubility of the substance had a low impact and it can be overcome by extended release formulation. Similarities between the two release profiles of AMD were confirmed by the values of difference factor (f1 = 43 697) and of similarity factor (f2 = 68.263).

CONCLUSIONS

During our conducted research, we assessed the *in vitro* release profile of AMD when formulated in a tablet matrix in two different states: as hydrochloride, and as HP-β-CD/AMD inclusion complex. Our results showed that AMD release in both studied formulas was similar and it was controlled only by the two matrix formers. The values of difference factor and similarity factor led us to confirm the similarities between the two release profiles of AMD. The studied tablets were obtained through direct compression and they contain low cost excipients, which will facilitate the transfer of optimal formulation to industrial production.

GENETIC SUSCEPTIBILITY TO INSULIN RESISTANCE ASSOCIATED WITH LOWER ADIPOSITY

The researchers tried to demonstrate the relationship between adiposity, genetic susceptibility to insulin resistance or insulin secretion and the response to GH treatment in short children born small for gestational age(SGA).The study was realised on 89 short prepubertal SGA children treated with GH for one year in a multicentre study. Combined multiallele gene scores based on single nucleotide polymorphisms with known associations with lower insulin sensitivity and insulin secretion were analysed. The results showed that during GH treatment, GS-In Res was related to a lesser decline in trunk fat and a higher trunk- limb fat ratio at 1 –year. GS-In Sec was positively associated with truncal fat.(Thankamony A[1,2], Jensen RB[1], O'Connell SM[3] et al. Adiposity in children born small for gestational age is associated with β-cell function, genetic variants for insulin resistance and response to growth hormone treatment. *J Clin Endocrinol Metab.* 2015 Nov 20:jc20153019**).**

AGGRESSIVE PERIODONTITIS: THE SUBGINGIVAL MICROBIAL PROFILE OF AN AFRICAN POPULATION

The aim of this study was to determine the subgingival microbial profile of African individuals from Sudan.The study was conducted on 34 patients from Kartoum, 19 of wich presented a form of aggressive periodontitis (AgP). The other 15 patients were periodontally healthy and considered as controls. For the determination of the subgingival microbial profile the following tests were used: real time PCR and DNA-DNA hybridization checkerboard. *Porphyromonas gingivalis* was absent from the samples in the AgP group, but present in two control patients. On the other hand, *Aggreggatibacter actinomycetemcomitans* was present in 6 of the 19 patients from the AgP group. The two periodontal „classic" pathogens were not significantly present in the AgP gruop, compared with the control group. More studies are needed in order to fully understand the subgingival microbial profile of aggressive periodontitis (Elabdeen HRZ, Mustafa M, Hasturk H et al. Subgingival microbial profiles of Sudanese patients with aggressive periodontitis. *J Periodont Res* 2016; 50: 674–682).

INFLUENCE OF CARBOXYMETHYLCELLULOSE SODIUM AND LUTROL ON THE SWELLING INDEX AND DISINTEGRATION TIME OF BIOMUCOADHESIVE TABLETS WITH MICONAZOLE NITRATE (Abstract): **Purpose.** To develop original pharmaceutical formulation with miconazole nitrate, biomucoadhesive tablets, used in antifungal medication. **Material and Methods:** The oral biomucoadhesive tablets with miconazole nitrate were developed by direct compression of the excipient mixture: carboxymethylcellulose sodium and lutrol 6000, excipients used for bioadhesivity, mannitol as a sugar substitute and aerosil as a lubricant. The main goal of the study is to determine the disintegration time and the swelling index of biomucoadhesive tablets with miconazole nitrate in order to estimate the time of contact with mucosa, respectively the prolongation of drug substance release. **Results:** The swelling index was calculated depending on time in all the 5 formulations that included the carboxymethylcellulose sodium and Lutrol 6000 as matrix-forming, and the studied were time and association ratio between polymers. **Conclusions:** Analysing the results, we noticed that out of the four excipients we used, carboxymethylcellulose sodium had the higher influence on the swelling index and disintegration time. **Keywords:** CARBOXYMETHYLCELLULOSE SODIUM, POLYETHYLENE GLYCOL 6000, SWELLING INDEX, MUCOBIO-ADHESIVE TABLETS.

To improve the bioavailability of the oral drugs, bioadhesive tablets have been developed in recent years (1). Oral adhesive tablets (2) can be applied in various areas of oral cavity, such as: palate, mucosa of the cheek, and between the gingiva and the upper lip. The tablet soaks, adheres to the substrate and is retained in its position until dissolution or its complete release. After a while, the tablet is no longer felt by the patient. Once positioned, the pharmaceutical formulation should not be moved in the mouth, since it causes an accelerated release of the product (3).

The excipients used in formulation of these pharmaceutical forms can influence the pharmaceutical – technological features and implicitly the swelling index (SI), an important parameter in setting the time of contact with mucosa, prolongation of the action and modified release.

SI is a generally studied parameter in

tablets with matrix-forming polymers as bioadhesion excipients. The polymers we used in preparing new bioadhesive formulations with miconazole nitrate and which offer bioadhesive capacity are PEG 6000 and carboxymethylcellulose sodium. This study analyses the values of SI, depending on quantity and type of the polymer.

The bioadhesive pharmaceutical formulations use adhesion as an including process, in which the adhesive agents penetrate the irregularities of the surface of the substrate and finally harden, producing many adhesive anchors. The process of establishing a continuous contact between an adhesive and a substrate is known as humectation. Humectation is closely related to the SI of the biomucoadhesive tablets.

The type of the polymer and its features are very important, because of the fact that bioavailability and efficiency of the pharmaceutical formulation depend on them (4, 5).

MATERIAL AND METHODS

Miconazole nitrate was used in the oral mucobioadhesive tablets as an antifungal active substance with 99% purity (14).

TABLE I

Mucobioadhesive tablet formulations with miconazole nitrate

Pharmaceutical substances mg/tablet	I	II	III	IV	V
Miconazole nitrate	25	25	25	25	25
Carboxymethylcellulose sodium (CMC-Na)	20	60	100	100	140
Mannitol	90	90	90	50	30
PEG 6000(Lutrol)	80	40	-	40	20
Aerosil	4	4	4	4	4
Total (mg)	219	219	219	219	219

Miconazole nitrate (Sigma Aldrich, Germany); *Carboxymethylcellulose sodium (*China Aroma Technology Co., Ltd. Zhejiang, China); *Mannitol (East Chemical, Weifang City, China) Polyethylene glycol - PEG 6000 microcrystalline powder (Lutrol, BASF Pharma, Germany)*; Aerosil (Degussa, Germany).

The working methods aimed at determining the swelling index (SI) of a mucoadhesive preparation, an important parameter for prolonged drug release and mucoadhesive action.

SI of the mucoadhesive tablets was determined by weighting a tablet of each formulation and recording the weights before placing them separately in a Petri dish. The individual initial weight is marked as (W_1).

15 ml of phosphate buffer (pH = 6.8) is added in each dish and the temperature is set for 37 °± 0.5°C. The tablets are taken out at regular period of times (60s, 120 minutes), are dried on a filter paper and weighted again (W_2).

The SI is calculated for each formulation using the formula: $SI = (W_2-W_1)/W_1$; where W_1 – the initial weight of the tablet; W_2 – the weight of the tablet after 60, respectively 120 minutes at 37ºC, in phosphate buffer solution.

The disintegration time was determined

according to USP 32, method A requested by FRX, on 6 tablets of each formulation (14). Through disintegration test, one can determine the time needed for transforming the tablets in fine particles when inserted in a liquid environment in specific working conditions. The data analysis was made in IBM *SPSS 20.*

RESULTS AND DISCUSSION

The specialised literature mentions several necessary features: rapid adherence to mucosa (6); strong interaction with mucin, respectively epithelial tissue (7); good capacity to stretch, moisten, swell, become soluble and biodegradable (8); keep its properties regardless of pH (9); not to influence the quantitative determination of the active substance (10).

Carboxymethylcellulose sodium (CMC-Na) is an anionic polymer, a cellulose derivative, used as a matrix system, due to its strong jellifying capacity (fig.1).

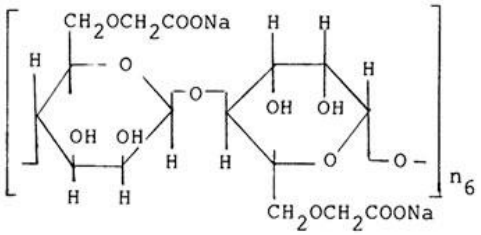

Fig. 1. Carboxymethylcellulose sodium

Carboxymethylcellulose sodium, also named croscarmellose, is a reticulated polymer, one of the hydrophilic materials, highly absorbing, with excellent swelling properties due to their fibrous nature, water soaking. Used for formulating bioadhesive tablets, croscarmellose offers good dissolution and disintegration, improving thus the bioavailability of the drug (11).

Considering its stronger hydrating properties, in comparison with hydroxypropyl methylcellulose, CMC-Na regulates the dissolution speed of the drug substances with low solubility (12).

PEG 6000 (Lutrol) is a last generation polymer, used in preparing bioadhesive pharmaceutical formulations, due to adhesive and moisture capacity (fig.2).

Fig. 2 PEG 6000

The weight of the tablets that were subject to the swelling test changed once with the swelling of the polymers in watery solution. The SI increased due to the fact that the weight of the tablets increased in direct relationship with the hydration speed up to 2 hours, and after that it decreased as a result of disintegration in dissolution environment. We noticed total disintegration when we added a smaller concentration of polymer (FI) in the formulation. This happened because of the erosion of the layer of gel in the tablets with smaller quantities of polymer (Table II).

The higher the value of SI is, the better the adherence of the tablet on the buccal mucosa will be, gradually releasing the antifungal. The highest SI is shown in formula FIII and formula FV, explained by the high quantity of added CMC-Na (fig. 3). We notice that the original formulations with miconazole nitrate have a good SI,

above 1.5, except for FI with a 0.86 SI, due to the small quantity of CMC-Na, which doesn't have the layer of gel around the tablet.

TABLE II

The swelling index of the bio adhesive tablets

Parameter	W_1 initial	W_2 at 60 minutes	W_2 at 120 minutes
Formula I	0.2185 g	0.4106 g	Tablet disintegrated
S.I.		**0.879**	-
Formula II	0.2210 g	0.5907 g	0.6369 g
S.I.		**1.67**	**1.88**
Formula III	0.2160 g	0.6680 g	0.7241 g
S.I.		**2.09**	**2.35**
Formula IV	0.2232 g	0.5231g	0.7322 g
S.I.		**1.34**	**2.28**
Formula V	0.2110 g	0.6500 g	0.7051 g
S.I.		**2.08**	**2.34**

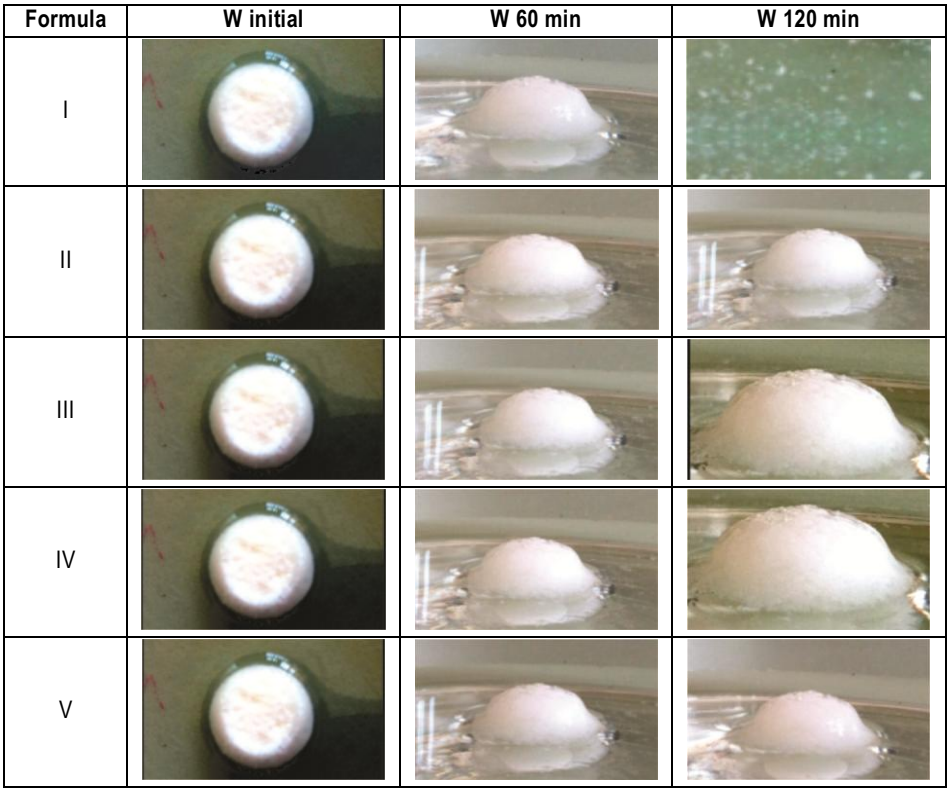

Fig. 3. The images of biomucoadhesive tablets with miconazole nitrate while determining the swelling index

Formula II has a 1.88 SI, a value explained by the quantity of used CMC-Na, 60 mg. Tripling the quantity of CMC-Na increased the value of SI, even if the value of PEG halved.

Composition of F III and F IV offers useful information about the capacity of the two polymers to influence the value of the SI.

In formula FIII, we only used CMC-Na as a matrix-forming polymer, obtaining a SI higher than 2, for the two time frames we included in the study.

Formula IV uses the same quantity of CMC-Na as formula III, but is also contains 40 mg of PEG as bioadhesive polymer. The value of SI at 60 minutes is smaller, 1.34, but it increases at 120 minutes at over 2, reaching a closer value to formula III, which proves that PEG 6000 does not influence directly the value of this parameter.

Formula V contains the biggest quantity of CMC-Na, 140 mg, together with a quantity of 20 mg Lutrol, which led to a value of 2.34 of the IU.

Figure 4 shows the necessary information for the high negative correlation with the additional marking of the point where SW = 2 and the corresponding concentration of Lutrol.

Hence, the value of SI also depends on quantity of PEG in the formulations we studied. After performing the Spearman test, we noticed in the above presented correlation scatter-plot that the ideal value of PEG is between 15 and 20 mg, a quantity we found in FV.

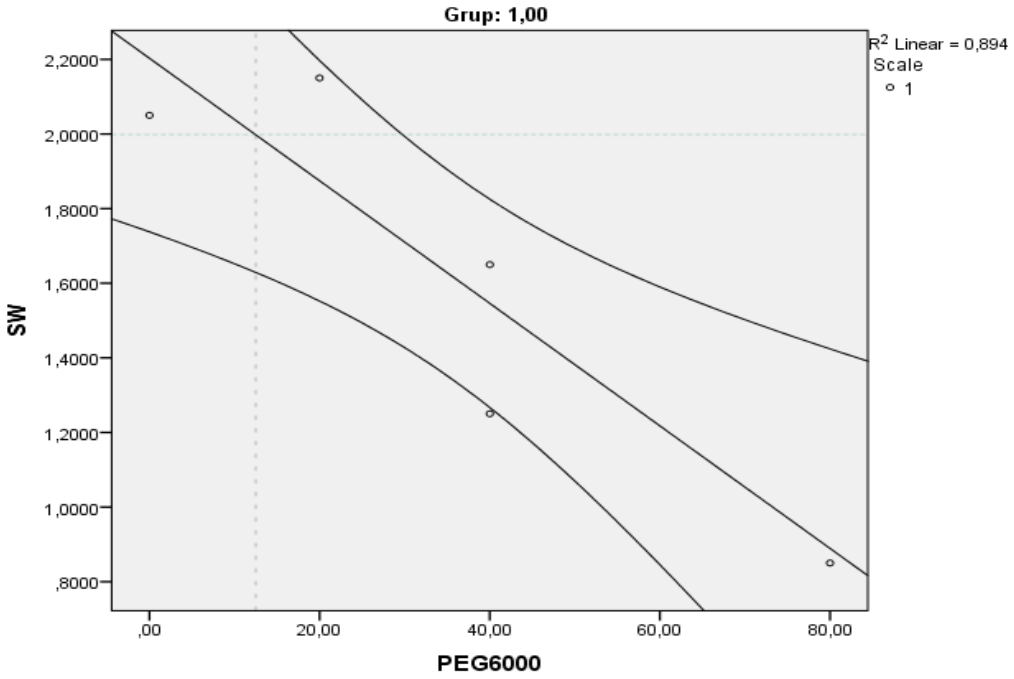

Fig. 4 Correlation Scatter plot between the swelling index and polymer PEG 6000

TABLE III

Descriptive statistics of the swelling index for formulations FI-FV of biomucoadhesive tablets with miconazole nitrate

	N	Minimum	Maximum	Mean	Std. Deviation
SW	5	.8790	2.0900	1.611800	.5153020
Valid N (listwise)	5				

The value of the SI for the biomucoadhesive tablets containing CMC-Na and Lutrol as matrix-forming excipients is between 0.88 and 2.09.

The polymers used for formulating the 5 types of biomucoadhesive tablets have a great influence on the disintegration time. The increase of the disintegration time can be highlighted by increasing the quantity of polymers. Carboxymethylcellulose sodium significantly influences the disintegration time. Formulations III, IV and V contain the biggest quantity of carboxymethylcellulose, therefore the longest disintegration time. This influence is confirmed by formula III and IV, which have the closest disintegration time. Formula IV disintegrates in 65 minutes, compared to formula III (60 minutes), due to the association of 100 mg of carboxymethylcellulose sodium with 40 mg of PEG, an excipient missing from formula IV. The lack of PEG does not significantly influence the disintegration time. Formula V shows the longest disintegration time, 90 minutes, due to the biggest quantity of carboxymethylcellulose sodium, 140 mg (fig. 5).

To conclude, PEG 6000, even if under 15% of the weight of the tablet, does not significantly influence the disintegration time, compared to CMC-Na, which, when over 5%, significantly influences the disintegration time.

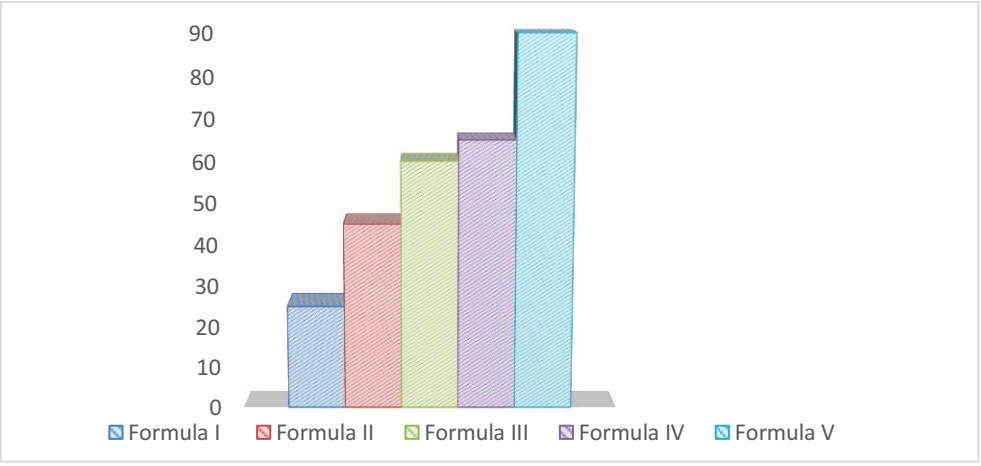

Fig. 5. Values of disintegration time, expressed in minutes

CONCLUSIONS

Our research showed that the ideal value of SI for biomucoadhesive tablets is 2. This value can be reached only if certain biomucoadhesive polymers are used, with the right concentration and the right ratio.

Our study shows the direct relationship between the quantity of carboxymethylcellulose sodium and the value of SI.

The disintegration time of biomucoadhesive tablets is influenced by the type and quantity of the polymers.

The disintegration time of over 60 minutes can be achieved with minimum 100 mg of carboxymethylcellulose sodium. The quantity of PEG in the proposed formulations does not significantly influence the value of the parameters we included in the study.

PHARMACISTS' PERCEPTION OF DOCTORS' PRACTICES OF DRUG PRESCRIPTION (Abstract). The promotion, prescription and dispensing of drugs are influenced by a series of factors and attempts to face dilemmas often distance companies, physicians or pharmacists from patients, those who are supposed to be the main beneficiaries of healthcare services. **Purpose of the study**: identifying pharmacists' perception of doctor's practices regarding drug prescription. **Material and methods**: A number of 72 pharmacists have answered a survey about doctors' practices of drug prescription to patients. Variables like age, work environment (urban, rural), length of employment have been taken into consideration. **Results**: in pharmacists' view, doctors take into consideration the protocol about 40% while they are prescribing; in their opinion, over 95% of doctors respect the budgetary limitations from the National Health Insurance House. They consider that 65% of doctors are influenced by their relationship with the medical representative. **Conclusions**: Pharmacists' view on doctors' prescribing is influenced by a number of factors. Few unethical practices of doctors are negatively appreciated by them. **Keywords**: PRESCRIPTION, ETHICS, PHARMACIST, DOCTOR, DRUG.

The promotion, prescription and dispensing of drugs are influenced by a series of factors and attempts to face dilemmas often distance companies, physicians or pharmacists from patients, those who are supposed to be the main beneficiaries of healthcare services. Prescribing drugs by doctors is both directly and indirectly. Direct methods include the various mechanisms within law designed to limit the prescription of pharmaceutical products. Indirect methods are those of persuasion, like medical education and techniques used by pharmaceutical representatives referring to aspects of the message, the source and the receiver (1, 2). Prescribing practices are often irrational and, by consequence, dangerous. There are a lot of studies that are shown that prescribing drugs by doctors are influenced by a lot of factors like physician's age, background education, and primary care patient load (3, 4).

Others studies put in evidence factors that influence prescribing include generic prescribing and knowledge of drug con-

tents, provincial drug programs, physician and patient characteristics, type of practice, source of information about drugs, and rapidity of adoption of new drugs (5).

Doctors' exposure to promotional campaigns leads to a rise in prescription rates (6). With very rare exceptions, direct exposure to campaigns conducted by pharmaceutical companies' results in: the frequent prescription of promoted medicine, price increase and a decrease in the quality of prescriptions. Many studies identify a risk in what concerns the quality of prescriptions per se, and raise a question about the veracity of drug prescriptions (7, 8).

Patients receive information about medicine through several channels, and they are under the pressure of advertising in pharmacies; however, in their turn, they put certain pressure on doctors and pharmacists (9).

MATERIAL AND METHODS

From January to May 2015, a number of 72 pharmacists answered a survey regarding their perception of drug dispensing by doctors. Variables such as age, work environment (urban, rural), length of employment was taken into consideration; the following items were defined in order to identify pharmacists' perception of the following behaviors exhibited by doctors:

1. criteria the doctor takes into account when prescribing a treatment (his personal experience with a certain molecule; meta-analyses related to the drug under discussion, published in specialized journals; the innovative character of the drug under discussion; the standard treatment protocol for the given diagnosis);

2. means by which the doctor covers the cost of his continuing education and training (sponsorships from the pharmaceutical industry; sponsorships from his employing institution; national and international projects/grants; personal resources);

3. criteria used by the doctor when prescribing a treatment (the patient's financial capacity; budgetary limitations from the *National Health Insurance House* (the possibility of compensation); the drug's availability in local pharmacies);

4. the importance of the doctor's relationship with the medical representative for the doctor's prescription of a certain drug;

5. doctors' recommendation of OTC products and supplements in addition to the treatment of the given pathology by RX medication;

6. prescribing drugs with international nonproprietary names (INNs);

7. prescribing INNs and, at the same time, recommending the brand name product.

The objectives of the research are the following:

1. qualitative analysis of pharmacists' answers to the 8 items listed above;

2. comparative analysis of results, depending on the following demographic variables of the batch of subjects: gender, background, education, geographic region of employment;

3. setting correlations between the variables of the survey and subjects' length of employment, age and experience in the field.

The survey was applied to 72 pharmacists aged from 24 to 68 (with an average age of 38 and a 10.57991 standard deviation), with 1-48 years of experience working in the pharmaceutical field (14.4265± 11.30489). 91.67% of the surveyed pharmacists are female and 90.28% work in pharmacies located in urban areas.

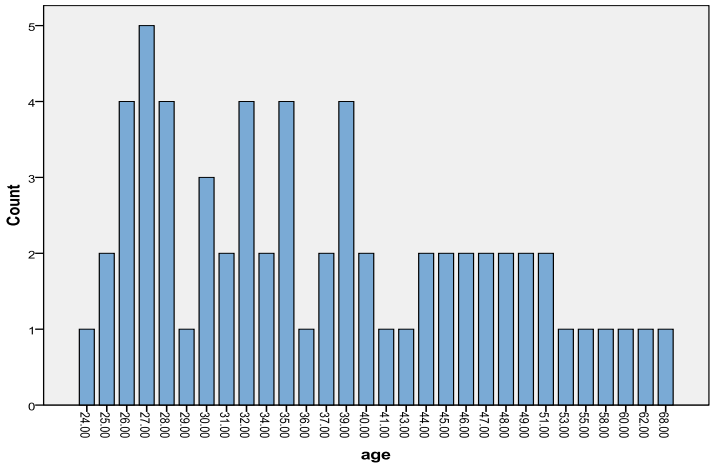

Fig 1. Distribution of pharmacists according to the age

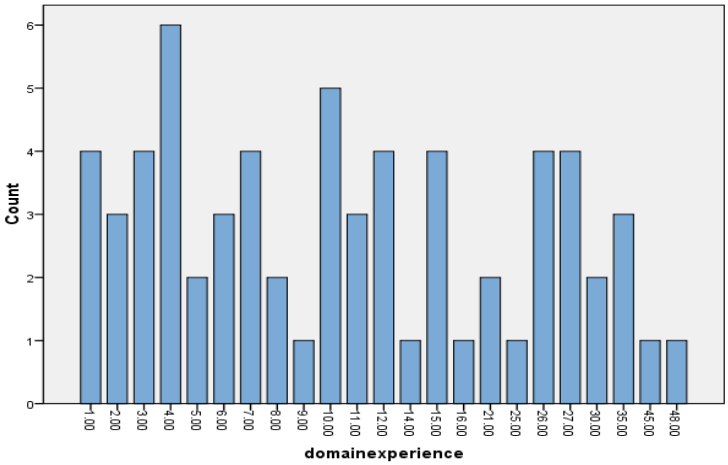

Fig. 2. Distribution of pharmacists according to the years of experience in the field

RESULTS AND DISCUSSION

In pharmacists' opinion, the criteria taken into account by the doctor when prescribing a treatment are:

a. personal experience with a certain molecule (average = 3.2154), for which never = 3.1%; rarely = 13.8%; often =41.5%; always = 41.5%;

b. meta-analyses related to the given drug, published in specialized journals (average = 2.5873), for which never = 12.7%; rarely = 33.3%; often = 36.5%; always = 17.5%;

c. the innovative character of the given drug (average = 2.5079), for which never = 7.9%; rarely = 44.4%; often = 36.5%; always = 11.1%;

d. the standard treatment protocol for the given diagnosis (average = 3.2097), for which never = 1.6%; rarely = 12.9%; often = 48.4%; always = 37.1%.

Regarding the means by which the doctor covers the cost of this continuing education and training, the pharmacists consider

that they are coming from:

a. sponsorships from the pharmaceutical industry (average = 2.7833), for which never = 6.7%; rarely = 30.0%; often = 41.7%; always = 21.7%;

b. sponsorships from the employing institution (average = 2.3333), for which never = 22.8%; rarely = 33.3%; often = 31.6%; always = 12.3%;

c. national and international projects/grants (average = 2.4754), for which never = 16.4%; rarely = 31.1%; often = 41.0%; always = 11.5%;

d. personal resources (average = 2.7833), for which never = 18.3%; rarely = 15.0%; often = 36.7%; always = 30.0%.

The criteria used by the doctor when prescribing a treatment are:

a. the patient's financial capacity (average = 3.0323), for which never = 3.2%; rarely = 24.2%; often = 38.7%; always = 33.9%;

b. budgetary limitations from the *National Health Insurance House* (the possibility of compensation) (average = 3.2807), for which never = 3.5%; rarely = 10.5%; often = 40.4%; always = 45.6%;

c. the drug's availability in local pharmacies (average = 2.7018), for which never = 7.0%; rarely = 31.6%; often = 45.6%; always = 15.8%.

Regarding the importance of the doctor's relationship with the medical representative for the doctor's prescription of a certain drug (average = 2.8475), for which never = 8.5%; rarely = 27.1%; often = 35.6%; always = 28.8%.

Regarding the recommendation of OTC products and supplements in addition to the treatment of the given pathology by RX medication (average = 2.9672), for which never = 0%; rarely = 27.9%; often = 47.5%; always = 24.6%.

Regarding the prescribing drugs with international nonproprietary names (inns) (average = 3.1746), for which never = 1.6%; rarely = 14.3%; often = 49.2%; always = 34.9%.

Regarding the prescribing international nonproprietary names (INNs) and, at the same time, recommending the brand name product (average = 2.7619), for which never =0%; rarely = 41.3%; often = 41.3%; always = 17.5%.

A comparative analysis of results was done, depending on the following demographic variables of the lot of subjects: gender, background, education, geographic region of employment. In order to highlight the difference between averages for the results obtained by our subjects depending on the considered demographic variables, we used the *t test* for independent samples.

The research obtained the following results:

a. According to the gender variable, there are significant differences between female and male subjects in what concerns the following variables:

- the patient's financial capacity as a criterion used in prescribing treatment by the doctor (3b) (t=2,051, p=.045), in that female subjects (M=4.00) consider that doctors use this criterion more frequently than male subjects (M=3.00);
- the importance of the doctor's relationship with the medical representative for the former's prescription of a certain drug (4) (p=-2,094, t=.041), in that female subjects (M=2.8750) consider the doctor's relationship with the medical representative more important for his prescription of a certain drug than male subjects (M=1.500);
- the recommendation of OTC products and supplements in addition to the treatment of the given pathology by Rx medication (5) (p=-2,094, t=.041), in that female subjects (M=2.8947) consider doctors' recommendation of OTC products and

supplements in addition to the treatment of the given pathology by RX medication less frequent than male subjects (M=4.00).

b. According to the (medical and non-medical) education variable, we obtained no statistically significant differences;

c. According to the background variable, there are statistically significant differences between subjects coming from a rural background and those from an urban background in what concerns the following variables:

- means by which the doctor covers the cost of his continuing education and training by sponsorships from the employing institution (2b) (t=-2,534, p=.014). Thus, subjects from urban backgrounds (M=2.2642) consider that doctors are less supported in their continuing education and training by sponsorships from their employing institutions than considered by subjects from rural backgrounds (M=3.6667);
- the importance of the doctor's relationship with the medical representative for the former's prescription of a certain drug (4) (t=-2,303, p=.025). Subjects from urban backgrounds (M=2.7636) consider that the doctor's relationship with the medical representative for his prescription of a certain drug is less important than considered by subjects from rural backgrounds (M=4.00).

d. According to the geographic region variable, there are statistically significant differences between subjects from regions Bacău and Neamț in what concerns the following variables:

- the criteria taken into account by the doctor when prescribing a drug, that is, meta-analyses related to that drug, published in specialized journals (1b) (t=-3,865, p=.004), in that subjects from Bacău (M=1.8333) consider that doctors use meta-analyses related to a drug published in specialized journals as a criterion for prescribing it less frequently than subjects from Neamț (M=3.4000);
- means by which the doctor covers the cost of his continuing education and training by sponsorships from the pharmaceutical industry (2a) (t=4.692, p=.001), in that subjects from Bacău (M=3.50) consider that doctors use sponsorships from the pharmaceutical industry as a means of covering the cost of their continuing education and training more frequently than those in Neamț (M=2.42);
- recommending OTC products and supplements in addition to the treatment of the given pathology by Rx medication (5) (t=3,029, p=.011), in that subjects from Bacău (M=3.8333) consider that doctors recommend OTC products and supplements in addition to the treatment of the given pathology by Rx medication more frequently than subjects from Neamț (M=2.8571);
- prescribing drugs with international nonproprietary names (INNs) (6) (t=2,171, p=.05), in that subjects from Bacău (M=3.8333) consider that doctors prescribe drugs with international nonproprietary names (INNs) more frequently than subjects from Neamț (M=3.2871).

In order to highlight the existing correlations between survey variables and subjects' length of employment, age and experience in the field, we carried out Spearman correlations.

Remotely significant statistically positive correlations are:

a. subjects' age and the importance of the doctor's relationship with the medical representative for the former's prescription of a certain drug (r= 340*, p=,015);

b. age and doctor's recommendation of OTC products and supplements in addition to the treatment of the given pathology by Rx medication (r=.,339*, p=.013);

c. work experience and sponsorships from the pharmaceutical industry as a

means by which the doctor covers the cost of his continuing education and training (r=,265*, p=.046);

d. work experience and sponsorships from the employing institution as a means by which the doctor covers the cost of his continuing education and training (r=,314*, p=.021);

e. work experience and the perception of the doctor's prescription of drugs with international nonproprietary names (INNs) (r=,295*p=.022);

f. experience in the field and the perception of the doctor's prescription of drugs with international nonproprietary names (INNs) (r=,316*, p=.018).

Strongly significant statistically positive correlations were pointed:

a. age and perception of the doctor's prescription of drugs with international nonproprietary names (INNs) (r=,416**, p=.002);

b. work experience and the importance of the doctor's relationship with the medical representative for the former's prescription of a certain drug (r=,394**, p=.003);

c. experience in the field and the importance of the doctor's relationship with the medical representative for the former's prescription of a certain drug (r=,462**, p=.001).

CONCLUSIONS

Our study proves that pharmacists' view on doctor's practices of prescribing drugs is influenced by a larger number of factors. Few practices of doctors are negatively appreciated by them. In their opinion, more than 95% are limited by the *National Health Insurance House* and over 64% are perceived like being influenced by the medical representative when they are prescribing drug to patients.

RISK FACTORS AND PREDICTORS OF CROSSBITE AT CHILDREN (Abstract). **Aim:** was to determine the etiological risk factors and predictors of crossbite' treatment at children. **Material and methods:** 270 cases with crossbites and 255 controls with other malocclusions were uniformly evaluated. The crossbites cases were divided in group I (anterior crossbite), group II (posterior crossbite) and group III (anterior and posterior crossbites) and were compared between them per Angle Class malocclusions, dysfunctional and dental causes, associations with other discrepancies, as well by need and types of treatment. Binary logistic regression was used to find risk factors and predictors. **Results:** The mean age of cases was 10.25±2.770 years. There were found significant differences between the groups of crossbites cases ($p<0.05$). There were identified risk factors (non-attrition of deciduous teeth, Angle Class II malocclusion and permanent teeth extraction) and protective factors of the crossbite (the tooth decay of deciduous teeth, eruption anomalies and tongue-thrust swallowing). There were found predictors for early corrective treatment (sucking habit, non-attrition and buds crowding) with a precision of 78.5%; for normal treatment (mouth breathing and buds crowding) with a precision of 71.5%; for late treatment (Angle Class III malocclusion, dental crowding and TMJ disorders) with a precision of 83.0%; for maxillary expansion (eruption anomalies and buds crowding) with a precision of 77.0%; for oral associated surgery (macrodontia and TMJ disorders) with a precision of 75.9% (HL test, $p>0.05$). **Conclusion:** The risk factors were dental furthermore; the predictors of treatment were adequate with dentition, etiology and disorders at age identification, suggesting the contribution of practitioners in intercepting this orthodontic emergency. **Keywords:** CROSSBITE, RISK FACTORS, TREATMENT, PREDICTOR FACTORS, CHILDREN.

Crossbite (CB) is the only malocclusion that requires emergency treatment as soon as possible, before maxillary discrepancies occur. The maxillary teeth positions are lingual to the mandibular teeth in centric occlusion. It can vary in clinical forms from one single tooth to all, and can be anterior or/and posterior and unilateral or/and bilateral (1, 2). Abnormal labiolingual relationship between upper and lower incisors is called anterior CB and between maxillary and mandibular canines, bicuspids or molars it is defined as posterior CB. The frequency found in population varies between 2.2-23 %, depending on the age, the racial group and types of CB studied (3, 4, 5).

CB can be a feature of some genetic and endocrine syndromes, but, usually it ap-

pears isolated (non-syndromic). CB etiopathogenesis is still unknown. Several forms of CB were associated with muscle and mandibular functional changes (6, 7), with delayed dental maturation (8), with temporomandibular joint (TMJ) disorders (9, 10), with craniomandibular asymmetry (11, 12, 13), or with leg length inequality (14). Previous study has not been reached a unanimous conclusion on the cause and effect relationship of CB. Many studies have focused on the CB treatment with various orthodontic appliances, but authors was not specified a causal therapy (3, 5). Also, predict factors CB' treatments are almost nonexistent in previous study.

Our study is based on the hypothesis that CB may occur due to determinants cause factors. The detection and early removal can be prevented future severe skeletal discrepancies. Correctives treatment options depend by development stage and of child at the moment of orthodontic intervention. Objects of our study were be to compare two samples of children and adolescents with same characteristics, with/without CB, with orthodontic treatment, to assess the mean age for detecting of malocclusions, etiological causes, oral status, need and types of CB' treatment. The aim of this study was to establish the possible risk factors for etiological causes of CB types and the accuracy of predictive factors for treatment options.

MATERIAL AND METHODS

Samples

This retrospective and case-control study was conducted for 525 orthodontic patients (217 - 41.3% males and 308 - 58.7% females) aged between 6-18 years old, at the Orthodontics Clinic from "St. Spiridon" University Emergency Hospital Iasi, Romania, between January 2009 and April 2013. The ethical approval was attained from the institute's ethical committee. 270 (51.4%) patients with CB were included as case samples and were divided in three groups, to the anomaly's location by group I with anterior CB (n=175 - 33.3%), group II with posterior CB (n=46 - 8.8%) and group III with anterior with posterior CB (n=49 - 9.3%). Patients with endocrine and genetic syndromes or clefts palate were excluded. The diagnosis was established by clinical and complementary exams (plaster cast, panoramic radiographs and lateral cephalometric radiography). All cases received orthodontic treatment. The control sample consisted in 255 (48.6%) patients without CB, being diagnosed with other malocclusions throughout the visit at the orthodontic office, in order to be compared with the case samples. The informed consent was acquired from all of the patients' parents.

Studied parameters

The data were collected from orthodontic records for both samples were uniformly evaluated per socially (age and gender) and oral status parameters (dentition stages and Angle Class malocclusion). The groups of CB cases were compared between them, introducing etiological parameters (dysfunctional and dental), associations with crowding, overbite, mandibular lateral deviation, jaw discrepancies and TMJ disorders, as well by need and types of treatment.

The skeletal discrepancies were established on lateral cephalometric radiography by measuring the angles between the points A Down, Nasion, B Down (ANB) in: Class I=ANB 2-4°, Class II=ANB>4° and Class III=ANB<2° (15). The treatment need was defined by the discrepancy of the teeth between retruded contact position and intercuspal position, using guidelines of Dental Health Components of the Index of

Orthodontic Treatment Need classifying them in moderate need (≤1 mm discrepancy), urgent need (with >1 mm but ≤ 2 mm discrepancy) and very urgent need (>2 mm discrepancy) (16).

Statistical methods

Statistical analysis was performed using the SPSS 16.0 package (SPSS Inc., Chicago, IL) for Windows. The data were characterized through descriptive statistics and cross tables; we used the chi-squared test to compare the variables between cases-controls and between the three groups of CB cases, in order to find the significant differences. The risk and prediction factors that were significant on binary analysis were brought into a forward stepwise binary logistic regression model (B) and the independent factors were determined. In order to select the most suitable model, the Hosmer-Lemeshow goodness-of-fit test (HL test) was used and a p value >0.05 was considered as good fit. Any association between the factors was tested using correlation, to eliminate the multicollinearity problems. The entire statistical analyses were conducted at 5% level of significance and p value <0.05 was regarded as significant.

RESULTS

The study included 525 orthodontic patients, 270 (51.4%) cases with a mean age of 10.96±3.225 years (males 10.82±3.079 years and females 11.06±3.331 years) and 255 (48.6%) controls with a mean age of 10.25±2.770 years (males 10.08±2.818 years and females 10.36±2.739 years). Their baseline characters were similar for both samples (tab. I). There were no significant differences between cases and controls in gender, dentition stages and Angle Class malocclusions (p>0.05).

TABLE I

Baseline characteristics of cases and controls

Characteristics	**Cases** (n=270)		**Controls** (n=255)		Chi-square	p value
	n	%	n	%		
Gender					0.005	0.943
Males	112	41.5	105	41.2		
Females	158	58.5	150	58.8		
Dentition stages					3.744	0.154
Early mixed dentition	66	24.4	78	30.6		
Late mixed dentition	107	39.6	103	40.4

Treatment types									
Expansion	169	62.6	95	54.3	32	69.6	42	85.7	0.000
Oral surgical	122	45.2	72	41.1	21	45.7	29	59.2	

Through the binary logistic regression model, we found statistically significant etiological risk factors, with an internal precision accuracy of 66.3% for all CB (HL test, p=0.890), of 66.5% for anterior CB (HL test, p=0.811), of 85.7% for posterior CB (HL test, p=0.994) and of 83.2% (HL test, p=0.449) for anterior with posterior CB. Value odds ratio (OR) <1.00 corresponds to protective factors (tab. III).

We found significant predictors for the precocious corrective treatment with a precision of 78.5% (HL test, p=0.708), for normal corrective treatment with a precision of 71.5% (HL test, p=0.821) and for late corrective treatment with a precision

of 83.0% (HL test, p=0.485), as well as for alternative methods of correction (overall percentage 77.0%, HL test, p=0.992 for maxillary expansion and 75.9%, HL test, p=0.102 for oral surgical) (tab. IV).

TABLE III

Binary logistic regression analysis of risk factors

Parameters	B	Wald statistic	p value	OR	95% Confidence Interval for OR	
					Lower bound	Upper bound

DISCUSSION

Early detection of a malocclusion and finding the cause-treatment relationship represents a necessity for practitioners, especially in emergency situations.

Complex analysis of types of CB in children compared with other malocclusions in order to establish the etiological risk factors and predictors of orthodontic treatment was investigated in this study. There were selected samples with same characteristics to avoid statistical errors. Patients without syndromes and clefts palate were selected, in order to avoid introducing additional variables, such as such as growth deficiencies, general skeletal and jaw development. The CB cases were divided into three groups and studied by comparisons. Types of CB presented highly significant differences, which explain the separate study of the clinical forms of CB by other authors (3, 5). We used multiple variables from clinical and complementary exams, which is an enhanced method against previous studies (17, 18).

The effects we pursued were focused on the relationship between age detection of malocclusions, cause, effect and therapy. According to the average age of the studied patients, the detection of CB was done in the period of late mixed and permanent dentitions, for both sexes. Identified at the early mixed dentition, CB benefit from a technique, which is simple, non-invasive, quick (3-6 months), and with minimal cost (19, 20, 21) Detected at the adolescent patient, the nature of intervention must be different, as a complex orthodontic and surgical treatment, for a longer time (2-3 years) and with a maximal cost (22, 23, 24).

Our binary logistic regression model found only dental causes as risk factors for the CB occurrence (non-attrition of deciduous teeth, Angle Class II malocclusion and permanent teeth extraction), which may be easily intercepted by practitioners. In addition, there were identified protective factors of the CB' (the tooth decay of deciduous teeth, eruption anomalies and tongue-thrust swallowing), which were not investigated by previous studies.

Predictors for corrective treatment options of CB were different according to the nature of the intervention. The buds teeth crowding and eruption anomalies were indicated for maxillary expansion in precocious and normal treatment. Macrodontia and TMJ disorders were indicated for oral surgical associated procedures in late treatments. In addition, sucking habit and mouth breathing were predictors for treatment in mixed dentition as well as dental crowding and Angle Class III malocclusion for treatment in young permanent dentition. These predictors were not identified in previous studies, dealing with predict factors for future mandibular growth of children with anterior CB (25).

CONCLUSIONS

Our case-control study revealed the following results: the mean age of malocclusions' detection was late; the groups of CB cases were highly significant different; etiological risk factors were only dental; protective factors of CB were identified; predictors of treatment were adequate to the dentition, etiology and disorders.

The study suggests the necessity of dental practitioners' involvement in intercepting this occlusal disorder. Similar further studies can be extended on other malocclusions that affect the young population's dental and facial esthetics.

PROTECTIVE EFFECTS OF PIOGLITAZONE AND/OR LIRAGLUTIDE ON PANCREATIC B-CELLS IN DB/DB MICE: COMPARISON OF THEIR EFFECTS BETWEEN IN AN EARLY AND ADVANCED STAGE OF DIABETES

Diabetes is a major health problem for developed and for developing countries and is considered the 21st century epidemic. The global prevalence of diabetes mellitus for all age groups was estimated to be 2.8% in 2000 and is projected to rise to 4.4% in 2030. Diabetes mellitus is a chronic disease caused by inherited and/ or acquired deficiency in production of insulin by pancreas, or by ineffectiveness of the insulin produced. Failure to maintain a normal level of glucose concentration in the blood can result in micro- and macrovascular complications. In type II diabetes insulin secretion is decrease due to pancreatic damage by "β-cell glucose toxicity" with beta cells mass affection and decrease proliferation of these. It is know that there is a statistically significant relationship between appropriate long-term blood glucose control and reduction of diabetic complications, so maintenance of strict glycemic control is necessary but this requires the preservation of β-cell function. Some anti-diabetic drugs, like thiazolidines and glucagon like peptide-1 receptor agonist possess a protective effect upon β-cells. The researchers was revealed that in obese type 2 diabetes model mice exhibiting significant hyperglycemia, compensatory hypertrophy of the islets can be seen in the early stage of diabetes but the capacity of such compensation is markedly attenuated in the advanced stage. The aim of this study was to compare the protective effects of pioglitazone and/or liraglutide on pancreatic β-cells between in an early and advanced stage of diabetes. The experiment was carried out for a period of 2 weeks with 20 diabetic rats that were divided into four groups of five rats each (group 1-4). Group 1 received Pioglitazone, group 2 – Liraglutide, group 3 - Pioglitazone and Liraglutide combination, group 4 – vehicle. During the entire period of experiment was determinate and monitored the body weight, food intake, insulin plasma concentration, cell apoptosis and proliferation in pancreatic islets. The results of this study showed that the food intake was significantly decreased just in an early stage, after 1 week of treatment, by Liraglutide and Liraglutide-Pioglitazone treatment and body weight gain was suppressed by Liraglutide and was significantly accelerated by Pioglitazone. Fasting blood glucose levels were significantly lower after Liraglutide and Pioglitazone treatment in early stage and it was enhanced by combination treatment. Plasma insulin levels in an advanced stage was lower than those in early stage. Liraglutide and Liraglutide-Pioglitazone treatments significantly reduced plasma glucagon concentrations compared with other groups in an early stage, but not in an advanced stage. After the evaluation of β-cell ratio and mass for all 4 groups in early and advanced stage it was showed that in an early stage, β-cell mass was increased in Pioglitazone and Liraglutide-treated mice, and the most significant effect was observed in the associated drugs group. In an advanced stage, on the other hand, the effect of these drugs on β-cell mass have not significant changes. In conclusion, protective effects of pioglitazone and/or liraglutide on pancreatic β-cells were more powerful in an early stage of diabetes compared to those in an advanced stage. (Kimura T, Kaneto H, Shimoda M et al. Protective effects of pioglitazone and/or liraglutide on pancreatic β-cells in db/db mice: Comparison of their effects between in an early and advanced stage of diabetes. *Mol Cell Endocrinol:* 2015; 400: 78-79).

RELIABILITY AND ACCURACY OF THREE DIFFERENT COMPUTERIZED CEPHALOMETRIC ANALYSIS SOFTWARE (Abstract): The aim of this investigation was to determine, compare and evaluate three different computerized tracing programs, where the lateral cephalograms were digitized on the screen. 39 randomly selected cephalometric radiographs were used in the present study. Three programs Planmeca Romexis® (Romexis 3.2.0., Helsinki, Finland), Orthalis (France) and AxCeph (A.C 2.3.0.74, Ljubljana, Slovenia) were evaluated. 12 skeletal, 9 dental and 3 soft tissue parameters were measured that consisted of 11 linear and 13 angular measurements. Statistical analysis was carried out using multivariate analysis of variance (MANOVA), Levene test, Tukey Honestly Significant Difference (HSD) test and Kruskal-Wallis test. The measurements obtained with the cephalometric analyses programs used in the study were reliable. **Keywords:** CEPHALOMETRIC ANALYSIS, COMPUTERIZED, LANDMARKS

Since Broadbent and Hoffrat has been developed cephalometrics (1) in 1931, this method it has become, especially in orthodontics field, essential in the diagnosis, treatment planning (2), result evaluation of cases treated with orthodontics, for analyzing both maxillofacial and orthodontic deformities, especially to evaluate growth and/or treatment changes (3, 4) and more recently, for evolution of orthognathic surgery.

Computers in assisting cephalometric analysis gained popularity and many authors highlighted that the linear and angular measurements were more precise in the digitally obtained radiographs, emphasizing that the quality of digital radiographs facilitates cephalometric measurements (5).

The aims and objectives of this retrospective study are to investigate the reliability between three computerized cephalometric programs to each other and to compare Steiner and Tweed analyses performed to the same patients with all three software.

MATERIAL AND METHODS

39 retrospective lateral cephalograms were taken from consecutively attending patients to radiographic clinic using a Planmeca ProMax 3D Mid (Planmeca,

Helsinki, Finland) device. 11 subjects were males and 28 were female, with age ranged between 7–33 years.

The inclusion criteria for the sample selection were as follows: the film with good quality and no unerupted or partially erupted teeth that will hinder landmark identification.

The exclusion criteria for the sample selection were as follows: history of previous orthodontic treatment, developmental abnormality such as cleft palate, cleft lip, and presence of gross facial asymmetry or deformity.

A total of 24 cephalometric measurements, 13 angular and 11 linear, commonly used to assess dentofacial relationships were selected. All measurements were performed twice by the same observer, with 14 days distance between them.

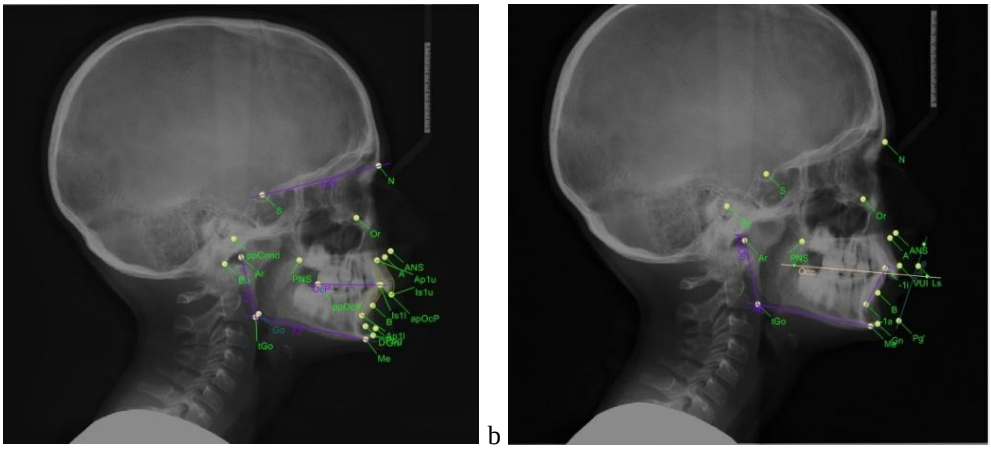

Fig. 1. a– Steiner Analysis; b – Tweed Analysis
(AX Ceph and Romexis Planmeca softwares)

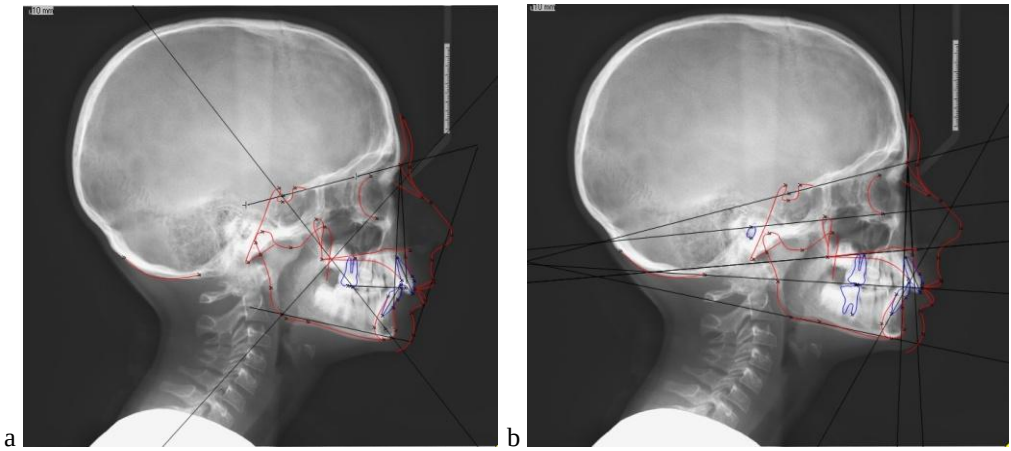

Fig. 2. a – Steiner Analysis; b – Tweed Analysis
(Orthalis software)

For all cephalometric radiographs evaluated in this study, the linear measurements were AO-BO (mm), Upper lip thickness (mm), Total chin thickness (mm), Anterior facial height (mm), Posterior facial height (mm), 1u-NA (mm), 1l-NB (mm), Pog-NB (mm), Holdaway Ratio (PO AND I TO NB) (mm), S-L (mm), S-E (mm), and the angular measurements were Frankfort-mandibular incisor angle (U1 to SN), Frankfort-mandibular plane angle, Incisor-mandibular plane angle, Occlusal plane, Z-Angle, SNA, SNB, ANB, SND angle, Inter-incisal angle, SN-OcP, SN-GoGn, Max1-NA (angle incisive superior), Mand-NB (angle incisive inferior), whence 12 skeletal parameters, 9 dentoalveolar parameters and 3 soft tissue parameters.

All the tracings were subjected to Steiner and Tweed cephalometric analysis (fig. 1 a, 2 a – Steiner Analysis and fig. 1 b, 2 b – Tweed Analysis)

RESULTS

The analysis was carried out for a confidence interval of 95%, research based on multivariate analysis of variance (MANOVA). The parameter p was our reference, which was calculated in all the tests, and the meaning of this parameter is the significance level of the test (p = 0.05). Results were presented as mean ± SD.

All the results from the study were summarized in table I and table II.

* r – Pearson correlation coefficient ** Lower Bound- Upper Bound (95% Confidence Interval for Difference)						

Pearson correlation coefficient allows assessment of the degree of concordance between the values measured by Ax. CEPH and Orthalis relative to the values measured with Romexis, which is considerate, the gold standard for this research.

Graphic illustration of the degree of concordance between the values provided by the three programs is shown in the following graphs (fig. 3 and fig. 4). Parameters situated under the red line show moderate or weak correlation.

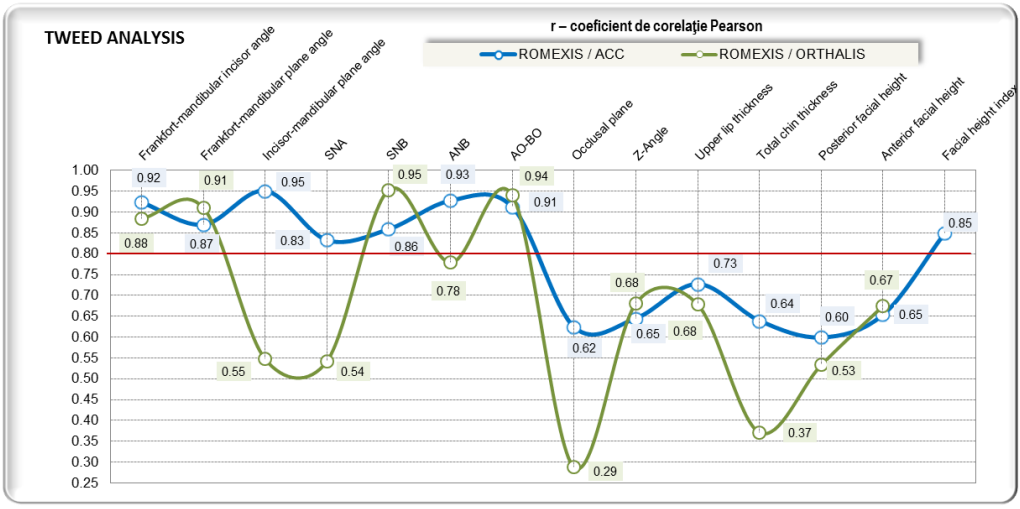

Fig. 3. Pearson correlation for values from Tweed Analysis, measured with Ax. CEPH and Orthalis, reported to Romexis software

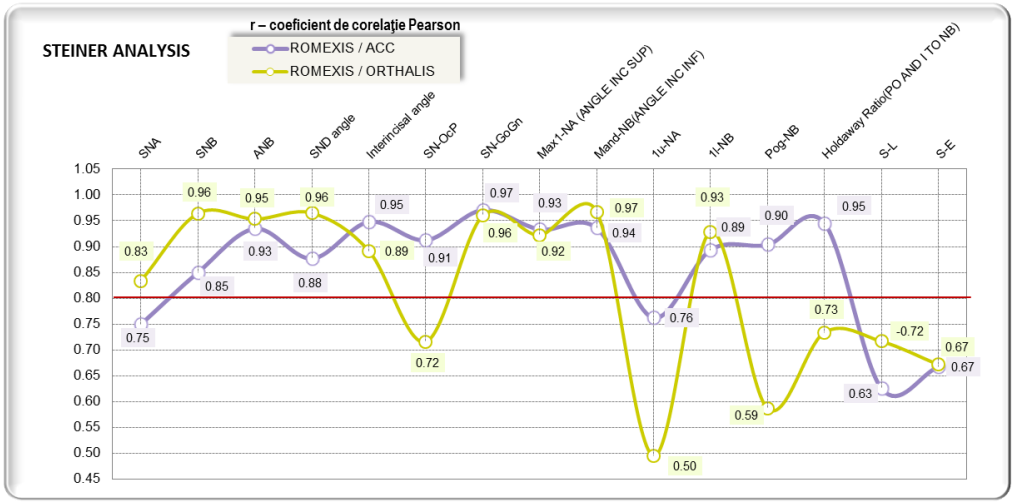

Fig. 4. Pearson correlation for values from Steiner Analysis, measured with Ax. CEPH and Orthalis, reported to Romexis software

DISCUSSION

The objective of this study was to assess the reliability of 2D cephalometric approaches by determining, comparing and evaluate three different softwares.

After a research in the literature, some of the papers with the similar purposes show a lack of criteria with regard to choice of cephalometric landmarks and the ideal linear/angular measurements to be used in studies (6, 7, 8, 9, 10).

Computer-assisted cephalometric analysis was found to be more precise and saving time; moreover, with digital cephalo-

grams obtained by digital radiography, the clinician identify the anatomic landmarks and let the program calculate automatically the cephalometric measurements (11).

Gravely and Benzies, in their research, sustain that, compare with hand tracing, computer-aided cephalometric analysis does not introduce less measurement errors in localization of the landmarks (12).

Recently, in 2004, Chen and co. revealed the fact that the difference between this two methods were statistically significant but clinically acceptable (6). A more recently study, concluded and presented a greater differences between this two methods for dental angular measurements (13).

In the present study, from the investigated measurements, 16 measurements were statistically significant: SNA, SNB, ANB, AO-BO, Z-angle, Upper lip thickness, Total chin thickness, SND, Posterior facial height, SN-OcP, SN-GoGn, Mand-NB, 1u-NA, 1l-NB, Pog-NB, PO and I – NB, S-E.

Statistical analysis founded significant difference between first method (Romexis – which is considerate gold standard in our study) and second method (Ax. CEPH) for 7 variables: Frankfort-mandibular plane angle, ANB, Occlusal plane, Z-angle, Upper lip thickness, Total chin thickness, S-E. Statistical analysis also revealed significant deifferences between second methods (Ax. CEPH) and third method (Orthalis) for 9 variables : SNA, ANB, Z- angle, SND, SN – GoGn, 1u – NA, 1l – NB, Pog – NB, S-E.

The computer method reduced, discretely, the possibility of differences, and it is clearly more secure than the manual method. However, in the present study, we found significant differences between three different computer methods.

For locating landmarks defined as being more inferior or deep in a given bone contour, points A, B and N, the computerized method proved to be more reliable than the traditional method (14).

Some studies sustain that cephalometric landmarks related to the location of N, B and A vertically, were difficult to reproduce them in the manual and computerized methods, but were similar (10, 15).

Linear measurements 1u-NA and 1l-NB, which require the location of points A and B show statistically significant differences in this study when comparing the measurements between Romexis / Ax. CEPH, with Pearson correlation r = 0.50; also we found no statistically significant differences when comparing first and second methods, r = 0.76. Other researcher found for this two linear measurements statistically significant differences when comparing manual with computer methods (10) and when comparing the manual tracing of Observer 2 with the computerized tracing of Observer 1 (16), and no significant differences when comparing the measurements of the manual and computerized tracings of Observer 1, when comparing interobserver computerized tracings, and when comparing the computerized tracing measurements of Observer 2 with the manual tracing measurements of Observer 1 (17).

Angular measurement SNGn, measurement that involves the landmark N, is difficult to locate in computer and traditional methods. With reference of this measurements, some of the previous study sustain that it is not statistically different in both methods of cephalometric tracing (17, 18).

The present study we did not measure the SNGn, but measure SNGoGn which show no statistical differences between this three methods, thus, for SN-OcP we found statistical differences between first method

(Romexis) and third method (Orthalis) with the Pearson correlation r = 0.72.

Soft tissue parameters used in the study, Upper lip thickness, Total chin thickness and Z-Angle, present significant differences. For Upper lip thickness the corelation between Romexis/Ax. CEPH was found more smaler (Mean Difference = -0.675, p = 0.013), with Pearson corelation r = 0.73, and the measurements between Ax. CEPH/Orthalis were more bigger, (Mean Difference=0.86, p<<0.01). For Total chin thickness the value from Ax. CEPH were smaller than Romexis, and the Pearson correlation between Ax. CEPH/ Romexis were r = 0.639 and between Romexis/ Orthalis were r = 0.371. For the last variable of the soft tissue, Z – angle, the measurements presented significant differences for all three methods. Between Romexis/Ax. CEPH (Mean Difference =2.76, p=0.015), and Romexis / Orthalis (Mean Difference=2.63, p=0.023), all this make visible a significant differences, resulting in that the values of Z – angle from Romexis are more bigger then other. Pearson corelation was poor for Ax. CEPH/ Romexis were r = 0.645 and Romexis/ Orthalis r = 0.68.

CONCLUSIONS

According to our results, Romexis and Ax. CEPH softwares are more reliable in measurements than Orthalis software.

The relevance of these differences will vary according to the objectives and purposes of the clinicians.

IN VITRO COMPARISON OF THREE DIFFERENT IMAGE RECEPTORS FOR DETERMINING THE LENGTH OF ENDODONTIC FILES

The correct evaluation of working length is one of the most important conditions of successful endodontic treatment. Both digital and traditional radiographs have been used for these assessments. However, the accuracy of these methods is still controversial. The aim of this study was to evaluate the accuracy of endodontic file length measurements of E-speed radiographs, Digora storage phosphor plates, and Schick charge-coupled device sensors, with a secondary aim of assessing the influence of image enhancement on the measurement accuracy. Forty-seven extracted mandibular first premolar teeth were selected. ISO size 8, 10, and 15 files were inserted into each canal, and the files were fixed when the tip was seen at the apical foramen. The teeth were mounted in acrylic blocks and exposed using E-speed films, Digora storage phosphor plates, and Schick charge-coupled device sensors. Two radiologists and two endodontists measured the length of each file between the file stopper and tip on each image. Measurements were carried out on original and magnified images as well as on revealer images for Schick CDR. The actual lengths of the files were measured using a calipers to the nearest 0.01 mm and served as the "true length". Repeated measures analysis of difference and Tukey honestly significant difference tests were used to analyze the data ($P < 0.05$). E-speed films were superior to digital systems for the measurement accuracy of the size 08 file ($P < 0.05$). Revealer images gave equivalent results with E-speed films for the measurement of the size 10 file ($P > 0.05$). The most accurate results were obtained with the size 15 file regardless of the image receptor ($P > 0.05$). Size 15 or larger files should be used for endodontic working length determinations. Revealer images gave equivalent results with E-speed films and may be utilized for determining the file length of size 10 files (Betul Ilhan, Ilgın Akcay, Nesrın Dundar. In vitro comparison of three different image receptors for determining the length of endodontic files. *Journal of Dental Sciences* 2014; 9(4): 345-350).

[2]Department of General and Oral Radiology

CBCT FINE PREOPERRATIVE EVALUATION OF INFLAMMATORY RADICULAR CYSTS AND POSTOPERATIVE LOCAL INTEGRATION APPRECIATION OF ALLOPLASTIC GRAFTS MATERIALS (Abstract): The purpose of this paper is to point out the value of CBCT exam in pre and postoperative diagnosis assessment of inflammatory radicular cysts together with full appreciation of local integration of alloplastic graft materials used to repair the osseous defects. There were statistically retrospective evaluated the pre and postoperative results of CBCT and x-ray examinations of 34 patients with inflammatory radicular cysts clinically, biologically and histopathologically assessed at Oral and Maxilo-Facial Surgery Clinic from Timisoara. In all cases we proceeded to surgical radicular cysts removement, extraction of the associated non-vital tooth together with alloplastic graft materials repairement of the osseous defects. The CBCT preoperative scans clearly showed the extent, the morphological characteristics and the topoanatomic reports, in all 34 cases of inflammatory radicular cysts together with regional endodontic status. The CBCT postoperative scans revealed the very local integration of alloplastic graft materials used to repair the osseous defects and, in some cases, the dental rehabilitation by metallic implants. CBCT scan is the imaging method of choice in pre and postoperative diagnosis assessment of inflammatory radicular cysts together with alloplastic graft materials repairement of the osseous defects and dental rehabilitation by metallic implants, due to high specific abilities in bone tissue 3D evaluation. **Keywords**: INFLAMMATORY RADICULAR CYSTS, ALLOPLASTIC GRAFT MATERIALS, CBCT SCAN

The dento-maxillary pathology is a major problem of medicine throughout the world due to the importance of this most anterior portion of the aero digestive tract with essential functions in: speech, mastication, taste, deglutition, aesthetics and general well being. The pathological conditions within the teeth and jaw bones will affect the integrity of the oral cavity with serious implications of all this functions. Any local disease could be the cause of regional and general complications which concern the whole organism with a great impact on health population (1).

The inflammatory radicular cysts are by far the most common pathological conditions within the teeth and jaw bones that will affect the integrity of the oral cavity

with serious implications of all his functions. The so common, inflammatory radicular cysts could be the cause of regional and general complications which concern the whole organism with a great impact on health population. Thus surgical radicular cysts removement and the associated non-vital tooth extraction are the treatment procedures of choice, with alloplastic graft materials repairment of the osseous defect and dental rehabilitation by metallic implants as the immediate required next steps (1, 2).

Examination and diagnosis of inflammatory radicular cysts by radiological and imaging modalities is the immediate of choice algorithm after clinical evaluation. Not only with the teeth and their surrounding bone the oral radiology concern, but also with the entire oral and maxillofacial complex (3, 4).

Among the imaging techniques of dental radiology the most common are panoramic and periapical radiographies together with the classical projections used in the diagnosis of maxilla and mandible pathology (4, 5).

Due to the ability of assessment of both the bone maxillary structures and the regional endodontic status with additional possibility of high-quality multiplanar reconstructions CBCT exam has proved to be an excellent procedure for characterizing the skeletal anatomy and related abnormalities of all oral regions being now the imaging modality of choice in pre and post-therapeutic daily practice (2, 3).

The aim of this paper is to point out the value of CBCT scan in pre and postoperative diagnosis assessment of inflammatory radicular cysts together with regional oral cavity extent, bone repair and dental rehabilitation by metallic implants evaluation.

MATERIAL AND METHODS

We retrospectively reviewed the pre- and postoperative results of CBCT and X-ray examinations of 34 patients with inflammatory radicular cysts clinically, biologically and histopathologically assessed at Oral and Maxilo - Facial Surgery Clinic from Timisoara. In all cases we proceeded to surgical removement, extraction of the associated non-vital tooth together with alloplastic graft materials repairement of the osseous defects and, in some cases, the dental rehabilitation by metallic implants.

All patients were pre and postoperative X-ray examined by dental radiographies obtained after the classical projection techniques protocol and by panoramic radiographies achieved with the usual orthopan tomographic procedure.

Preoperative and post terapeuthic surgical and grafting skeletal and dental procedures CBCT scans were done with the same unit with multiplanar and 3D reconstruction in order to precise regional oral cavity extent and dento-maxillary rehabilitation evaluation.

RESULTS AND DISCUSSION

From the 34 patients with inflammatory radicular cysts, 19 cases (56%) were detected in the mandible and 15 cases have maxillary localization (44%). In mandible 12 cases (63%) were found in aesthetic anterior regions and 7 cases (37%) have non aesthetic posterior localization. In maxillary regions 9 cases (60%) were revealed in aesthetic anterior regions and in 6 cases (40%) the sites were in non aesthetic posterior region.

In all cases radicular cysts removement and the associated non-vital tooth extraction ware the treatment procedures of choice, with alloplastic graft materials repairement

of the osseous defect and in 9 mandibular cases (47%) and only in 6 cases (40%) with maxillary localization we proceed to dental rehabilitation by metallic implants.

Fig. 1. The multiplanar and 3D CBCT- scans and X-ray exam in a pre and postoperative case of left posterior mandible inflammatory radicular cysts with surgical removal and alloplastic graft materials repairement of the osseous defect.

In all patients periapical and panoramic radiographies revealed complete bone lysis done by inflammatory radicular cysts and fine alloplastic graft materials repairement

of the postoperative osseous defect but the CBCT scans were a great deal more accurate in describing the orientation, vicinity and extent in all 3 plans of the lesions.

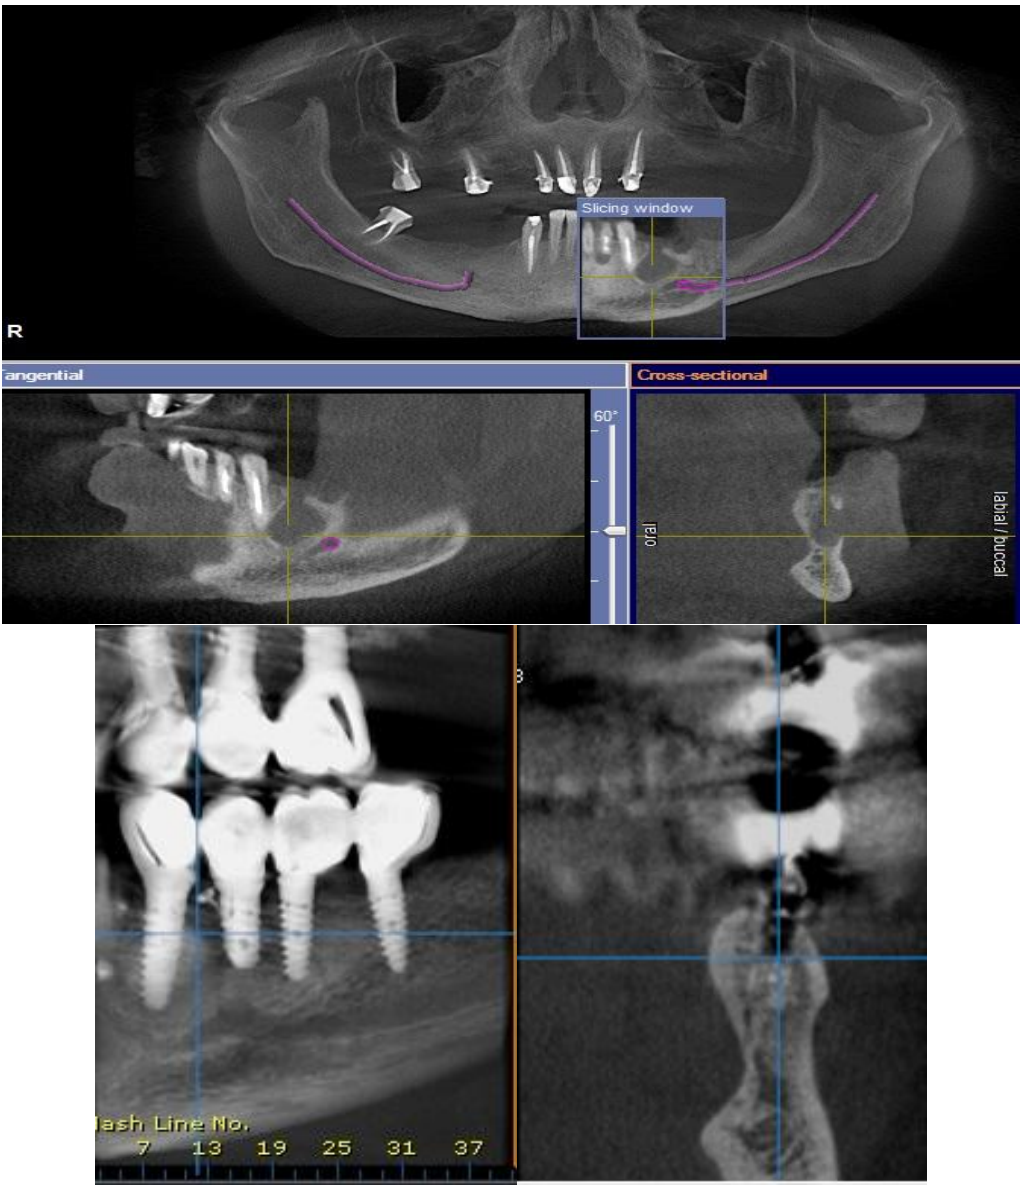

Fig.2. The multiplanar and 3D CBCT- scans in a pre and postoperative case of left anterior mandible inflammatory radicular cysts with surgical removal, alloplastic graft materials repairement of the osseous defect and dental rehabilitation by metallic implants.

In patients with dental rehabilitation by metallic implants we clearly evaluated by CBCT scans the proper alignment, parallelism, direction and mezodistal and

interproximal spacing in aesthetic zone in. The good locations and buccolingual angulations of the implants in non aesthetic zone were investigated with added extra information by postoperative CBCT scans tissue 3 D analyses.

CONCLUSIONS

The CBCT - exam offer a detailed evaluation of the dento-maxillary region together with the accompanying vital structures: the floor of the sinus, the floor of the nose, the roof of the mandibular canal and the position of the mental neurovascular bundle.

CBCT - exam is the imaging modality of choice in the diagnosis algorithms of inflammatory radicular cysts offering high abilities in the evaluation of bone tissue by multiplanar and 3D reconstruction.

CBCT - scan are of great importance value in patients with inflammatory radicular cysts being able to offer subtle and no doubt data for precise skeletal extent diagnosis and local dental status in order to proceed a clearly quantificated treatment with accurate capacities in postoperative evaluation.

The CBCT - exam offer a detailed precise evaluation of alloplastic graft materials integration used in the postoperative osseous defect repairement and proper alignment, parallelism, direction, spacing and angulations in patients with dental rehabilitation by metallic implants.

ECHINOCANDINS - NEW ANTIFUNGAL AGENTS

ECHINOCANDINS - NEW ANTIFUNGAL AGENTS (Abstract): Over the past 10-15 years, the number of clinically available antifungal agents has increased substantially, due to rise in the number of invasive fungal infections, which are a real problem for specialists. Echinocandins are the new class of antifungal agents available for clinical use. This class comprises over 20 natural echinocandins and several semisynthetic ones. Natural echinocandins are not of clinical utility due to their toxicity and low water-solubility (which does not allow obtaining parenteral pharmaceutical forms), although they have good antifungal activity against *Candida* species. Consequently, semisynthetic echinocandins with minimal toxicity, good antifungal activity and high water-solubility were obtained. All echinocandins inhibit β-1,3-glucan-synthase, an essential component of the fungal cell wall. Echinocandins exhibit potent antifungal activity against key pathogenic fungi, including *Candida* species, *Aspergillus* species and *Pneumocystis carinii*. The available echinocandins lack in vitro activity against *Cryptococcus neoformans*. The semisynthetic echinocandins have great advantages, among which low toxicity, fast antifungal activity, favorable pharmacokinetics that allow once-daily administration. The echinocandins recently available for clinical use are: caspofungin, micafungin and anidulafungin. **Keywords:** MICAFUNGIN, ECHINOCANDINS, CASPOFUNGIN, PNEUMOCANDIN, ANIDULAFUNGIN

Antifungal agents were discovered quite late, although some species of pathogenic fungi were discovered in 1835 (Beauvaria bassiana).

Despite intense research carried out in order to discover new antifungal agents, they appeared later than the antibacterial antibiotics on the pharmaceutical market. This happend because it was difficult to find good antifungal agents with low toxicity.

Antifungal agents can be categorized depending on how they are obtained as synthetic antifungal agents and natural antifungal agents (tab. I) (1).

Nowadays, the natural antifungal agents most often used in therapy are: polyenic macrolides (nystatin, natamycin, amphotericin B), spiranic antibiotics (griseofulvin) and cyclic lipopeptide antibiotics (candins- the most popular being echinocandins).

Other natural compounds are in different stages of clinical testing:

- papulacandins – glycolipid antibiotics produced by Papularia species;

- pradimicins and benanomycins – antracyclic antifungal agents isolated from

cultures of actinomycetes;

- nikkomycins and sardarins – antifungal agents isolated from cultures of actinomycetes.

TABLE I

Natural antifungal agents

No	Antifungal agent	Producing miroorganism	Pharmaceutical products
1.	Amphotericin B	Streptomyces nodosus	Fungizone, Fungilin
2.	Azaserin	Streptomyces spp.	-
3.	Candicidin	Streptomyces griseus	Levorin, Vanobid
4.	Dermostatin	Streptomyces viridogriseus	Viridofulvin, Dermastatin
5.	Fungicromin	Streptomyces cellulosae Streptomyces penticus Streptomyces roseoluteus Streptomyces griseus	Cantricin
6.	Filipin	Streptomyces filipenensis	Filimarisin
7.	Griseofulvin	Penicillium griseofulvum Penicillium janczewskii	Fulvicin, Grisactin, Fulcin, Grifulvin
8.	Hachimycin	Streptomyces hachijoensis	Trichomicin, Trichonat
9.	Hamycin	Streptomyces pimprina	Primamycin
10.	Lucensomycin	Streptomyces lucensis	Etruscomicyn,
11.	Natamycin	Streptomyces natalensis Streptomyces chattanoogensis	Pimaricin, Natacyn Pimafucin, Mycophyt
12.	Nystatin	Streptomyces noursei, Streptomyces aureus	Stamicin, Nistatin, Fungicidin, Mycostatin
13.	Partricin	Streptomyces aureofaciens	Ayfactin
14.	Pecilocin	Paecilomyces varioti Bainier var. antibioticus	Supral, Variotin
15.	Perimicin	Streptomyces coelicolor var. aminophilus	Aminomycin
16.	Pirrolnitrin	Pseudomonas pyrrocinia	Pyroace
17.	Siccanin	Helminthosporium siccans Drechsler	Tackle
18.	Trichomycin	Streptomyces hachijoensis	Trichomycin

Echinocandins were discovered in the 70's and 80's, being natural lipopeptidic antibiotics active against the resistant strains of Candida and Aspergillus. These are the most recently aproved antifungal agents, after years of intense research (2, 3).

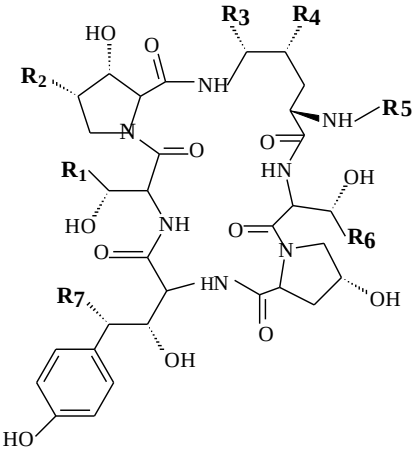
Candida species are the fourth leading cause of nosocomial infections in USA, mortality from candidiasis is reported to be 38% in imunocompromised persons, and complications could appear in over 15% of patients (4, 5). Moreover, during the past decade, the incidence of invasive aspergillosis has increased, especially in imunocompromised, cancer, and transplant patients (6).

Amphotericin B or fluconazole are the first-line therapeutic options in the treatment of such fungal infections, but the utility of amphotericin B is limited due to its nephrotoxicity. Fluconazole is relatively safe, but there are already Candida species resistant to it.

Therefore, because invasive candidiasis and aspergillosis are severe nosocomial infections, there was an urgent need for new antifungal agents. The recent discovery and development of echinocandins is an alternative to amphotericin B and fluconazole as first-line treatment for candidiasis.

Echinocandins are large amphiphilic cyclic hexapeptides molecules with the N-linked acyl fatty acid ("side chain") with a length of 14 to 18 carbon atoms (1).

Echinocandins are a class represented by over 20 isolated natural products, which are divided into several subclasses, and many semisynthetic analogues, derived from natural compounds (fig. 1).



No	Echinocandin	Fatty acid side chain (R5)
1.	Echinocandin B	Linoleic acid
2.	Echinocandin C	Linoleic acid
3.	Echinocandin D	Linoleic acid
4.	Aculeacin Aγ	Palmitic acid
5.	Mulundocandin	12-Methylmyristoic acid
6.	Sporiofungin A	10,12-Dimethylmyristoic acid
7.	Pneumocandin A0	10,12-Dimethylmyristoic acid
8.	Pneumocandin B0	10,12-Dimethylmyristoic acid

Echinocandin	R1	R2	R3	R4	R6	R7
Echinocandin B	CH3	CH3	OH	OH	CH3	OH
Echinocandin C	CH3	CH3	OH	OH	CH3	H

Pneumocandin B0	CH2CONH2	H	OH	OH	CH3	OH

Fig. 1. Natural echinocandins

All natural echinocandins are active by inhibiting enzyme 1,3-β-D-glucan synthetase, being selective and noncompetitive inhibitors of the essential components of the fungal cell wall biosynthesis, making it easy to lysate (1, 7). The enzyme is not present in the cell wall of higher animals, which explains the very few side effects

caused by echinocandins.

They have the advantage of low toxicity, fast antifungal activity and favorable pharmacokinetic that allows once-daily administration (having large molecules should only be given intravenously).

The spectrum of natural echinocandins is limited to Candida species (spp.), but some semisynthetic analogues have a wider spectrum that includes other endogenous fungi, such as: Aspergillus spp., Pneumocystis carinii etc. None of these compounds show activity againts Cryptococcus neoformans strains.

Echinocandin B was first isolated and identified as the major component of the class (which includes echinocandin C and D). It was isolated from the fermentation broths of various fungi of the genus Aspergillus nidulans and Aspergillus rugulosus in 1974, at the same time by the researchers from Ciba-Geigy, Sandoz, and Eli-Lilly. Researchers from Toyo Jozo have isolated echinocandins from aculeacin class, and fermentations broths of Aspergillus aculeatus, those from Hoechst have isolated mulundocandin from Aspergillus sydowi and sporiofungin class was isolated from Criptosporiopsis spp. by Sandoz researchers. The pneumocandin class, with the main component pneumocandin B0, was isolated from the fermentations broths of some fungi of the genus Zalerion arboricola and Glarea lozoyensis by Merck researchers in 1985.

All these compounds are substances with low water solubility, being discovered quite recently. Of these, only the echinocandins and pneumocandins were studied more closely for the development of semisynthetic derivatives.

Natural echinocandins and natural pneumocandins have no therapeutic utility due to their toxicity (they are hemolytic substances), although they have very good antifungal activity against Candida strains (8). They also have low water solubility, which makes them difficult for parenteral formulations. Thus, semisynthetic compounds, non-toxic, with high antifungal activity and enhanced water solubility were obtained. Today three semisynthetic echinocandins, caspofungin, micafungin and anidulafungin are licensed for clinical use (9).

Starting with the natural candins isolated from the culture medium of Glarea lozoyensis species a semisynthetic analogue of pneumocandin B0, called Caspofungin (fig. 2) was obtained and entered the U.S. market in 2001 by Merck (CANCIDAS - Merck, USA, vials 50 or 70 mg lyophilized powder). In Europe it was introduced in therapy in 2002 (CANCIDAS, Merck & Co. Inc., USA, MK-0991). The pharmaceutical product contains caspofungin acetate a water-soluble salt of caspofungin. ($C_{52}H_{88}N_{10}O_{15}\cdot 2C_2H_4O_2$).

It has a good pharmacokinetics: 100% bioavailability, high plasma protein binding (97%) and a half-life of 9-11 h. It has a slow hepatic metabolism and a slow elimination from plasma with a clearence of 10-12 mL/minute. Excretion of drug is through hepatic (34%) and renal (41%) routes. A small amount of caspofungin is excreted unchanged in urine (1.4%).

Caspofungin acetate inhibits the synthesis of 1,3-β-D-glucan synthetase, an essential component of the cell wall of many filamentous fungi.

It is active against Candida albicans, Candida tropicalis, Candida glabrata, Candida krusei, Candida lusitaniae, Candida dubliniensis and Aspergillus species, but is also active against Pneumocystis jirovecii

(7, 10, 11, 12). It is less active against Candida parapsilosis and Candida guilliermondii, with higher minimum inhibitory concentrations for these species. Caspofungin has limited activity against other fungi (e.g. Trichosporon beigelii, Rhizopus arrhizus, Fusarium spp.) and its activity against other pathogens (e.g. protozoa) is undergoing clinical evaluation (13). The minimum inhibitory concentrations (MIC50) of caspofungin against Candida albicans ranges from 0.01 μg/mL to 8 μg/mL (14).

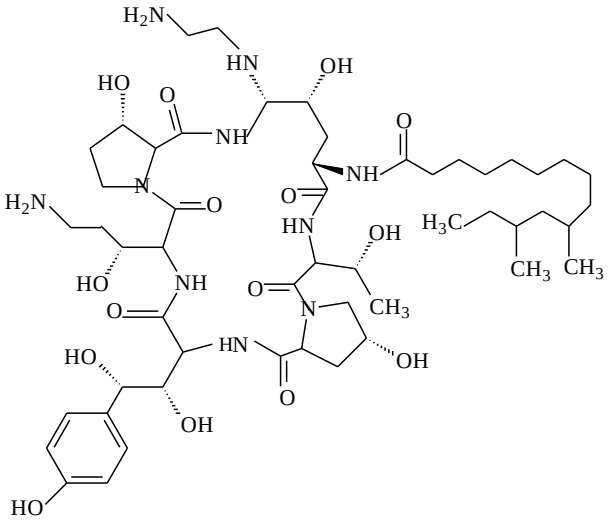

Fig. 2. Chemical structure of Caspofungin

It is administered only intravenously (i.v.), the solution is reconstituted by dissolving the powder exclusively in 0.9% NaCl solution. It is not compatible with dextrose, so diluents containing dextrose have to be avoided. Caspofungin is provided as a lyophilized powder and excipients include sucrose, mannitol, acetic acid, and sodium hydroxide. It can be stored (refrigerated) for up to 24 h after reconstitution (14).

Caspofungin (CANCIDAS) is administered intravenously as first-line treatment for Candida infections: intra-abdominal abscesses, peritonitis, pleural infections and in the treatment of esophageal candidiasis. It is indicated to treat adults, adolescents and children with invasive candidosis and invasive aspergillosis when the patient does not respond to or does not tolerate amphotericin B or itraconazole. (15, 16, 17, 18). It is used successfully in the treatment of invasive candidiasis in immunocompromised patients (19).

Another analog of pneumocandin B0 is Micafungin (fig. 3), a semisynthetic echinocandin obtained by conversion of the natural compounds isolated from fermentation broths of Coleophoma empetri F-11899.

Micafungin is manufactured in Japan and commercialized by Astellas Pharma under the trade name MYCAMINE (Micafungin sodium, 50 mg or 100 mg lyophilized powder per vial). The product has received U.S. market approval from Food and Drug Administration (FDA) on 16 March 2005. European Medicines Agency (EMA) has given approval for European market on 25 April 2008 (MYCAMINE, Astellas Pharma Inc., USA, FK-463).

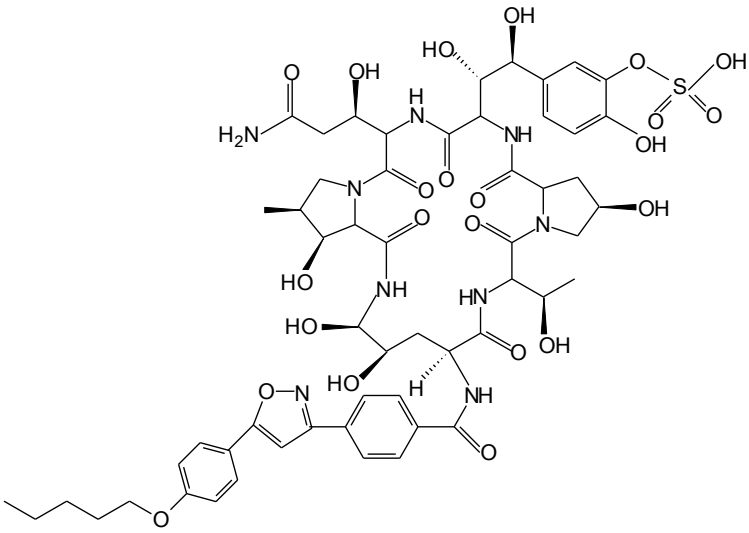

Fig. 3. Chemical structure of Micafungin

Micafungin is a semisynthetic echinocandin, presented as a white hygroscopic powder. The pharmaceutical product contains sodium micafungin a salt readily soluble in water ($C_{56}H_{70}N_9NaO_{23}S$).

It is active against strains of Candida albicans, Candida glabrata, Candida krusei and Candida tropicalis. It is less active against Candida parapsilosis and Candida guilliermondii, with higher minimum inhibitory concentrations for these species. The minimum inhibitory concentrations (MIC50) of micafungin against Candida albicans ranges from 0.01 μg/mL to 0.5 μg/mL (14). Micafungin is characterized by linear pharmacokinetics. It is metabolized into three metabolites which are excreted slowly over many days, mainly in the bile. It is highly bound to plasma protein (99%), and the half-life is 10-17 hours. Micafugin is eliminated via digestive (40%) and renal (15%) routes.

Micafungin is administered intravenously, once daily, to treat Candida infections such as intra-abdominal abscesses and peritonitis (20, 21). Micafungin is approved for use in neonates, children, adults and adolescents in the treatment of invasive candidosis. It is also used, from January 2008, in the prophylaxis of candida infection in patients undergoing allogeneic hematopoietic stem cell transplantation or patients who are expected to have granulocytopenia (22). In addition, micafungin is used in the treatment of esophageal candidosis in adults.

It has few side effects, like other semisynthetic echinocandins being very well tolerated. However, patients who develop abnormal liver function tests during treatment with micafungin should be evaluated for the risk/benefit ratio.

The vials contain sodium micafungin and excipients which include lactose, citric acid and sodium hydroxide. The lyophilized powder is ready for reconstitution by dissolving with NaCl 0.9% or dextrose 5%.

Reconstituted solution is stable at room temperatures for 48 h, if protected from light.

An analogue of echinocandin B is Anidulafungin (fig. 4), marketed by Pfizer (U.K.).

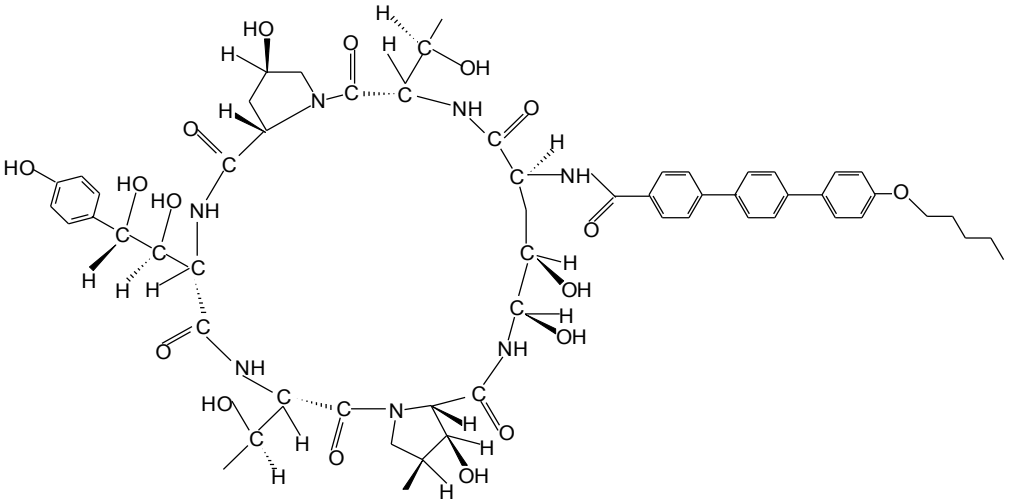

Fig. 4. Chemical structure of Anidulafungin

Pfizer received U.S. market approval from FDA for anidulafungin under the trade name ERAXIS (50 mg or 100 mg vials containing lyophilized powder) in February 2006. EMA has given approval for European market on November 2007 for anidulafungin under the trade name ECALTA (50 mg or 100 mg vial containing lyophilized powder, Pfizer Inc. UK).

It is a semisynthetic echinocandin obtained by converting natural echinocandin B isolated from Aspergillus nidulans species. It was initially researched by Eli Lilly, clinically developed by Vicuron company, and later marketed by Pfizer.

It is a white powder ($C_{58}H_{73}N_7O_{17}$), freely soluble in water, with an alkoxytriphenyl side chain which intercalates with the phosphor-lipid bilayer of the cell membrane.

It is active against strains of Candida albicans, Candida glabrata, Candida krusei and Candida tropicalis. It is less active against Candida parapsilosis and Candida guilliermondii, with higher minimum inhibitory concentrations for these species (23). The minimum inhibitory concentrations (MIC50) of anidulafungin against Candida albicans ranges from 0.01 μg/mL to 8 μg/mL (14). On other fungi anidulagfungin activity is limited (e.g. Acremonium spp., Phialophora spp., Rhizopus spp., Fusarium spp.).

Anidulafungin is slowly metabolized into an inactive open-ring peptide which is excreted in the bile. No liver metabolism has been observed. It is highly bound to plasma protein (99%), and the half-life is 0.5-1 hour. It is eliminated via digestive (30%) and renal (1%) routes.

Anidulafungin is administered intravenously to treat invasive candidosis, invasive aspergillosis in adults who are not

granulocytopenic, but not in children or adolescents below the age of 18 years (23). It is administered once-daily, the duration of treatment depending on patient response, usually at least 14 days. It has few side effects, like other semisynthetic echinocandins being very well tolerated. It can be used in patients with renal and hepatic impairment (14, 23, 24).

The vials contain anidulafungin and excipients as a lyophilized powder. The excipients include fructose, tartric acid, manitol, sodium hydroxide and hydrochloric acid. The lyophilized powder is ready for reconstitution with water for injections and subsequently diluted with NaCl 0.9% or glucose 5% for infusion. Reconstituted solution is stable at room temperatures for 24 h.

Echinocandins are the newest antifungal agents available for clinical use. The semisynthetic echinocandins have great advantages such as, low toxicity, great antifungal activity, high water solubility, and favorable pharmacokinetics, which allow once-daily intravenous administration. They exhibit potent antifungal activity against key pathogenic fungi, including Candida species, Aspergillus species and Pneumocystis species. All clinical trials demonstrate their efficacy in the treatment of invasive candidosis and invasive aspergillosis in patients not responding to other antifungal agents. They can be used successfully in the treatment of invasive candidiasis in immunocompromised patients, or in patients with renal and hepatic impairment.

The echinocandins recently available for clinical use are: caspofungin, micafungin and anidulafungin.

Their safe use, route of administration, fewest interactions with other drugs and their spectrum of action make echinocandins a class of antifungal agents with a secure future, although today they are less accessible due to the cost.

POSSIBILITIES TO ACYLATE 7-AMINOCEPHALOSPORANIC ACID TO OBTAIN SOME CEPHALOSPORINS (Abstract): **Aim**: Acylation of 7-aminocephalosporanic acid with an adequate acyl chloride in order to obtain cefotaxime sodium salt. **Material and methods**: Cefotaxime sodium salt was synthesized by acylating 7-amino cephalosporanic acid with 2-[2`-chloracetamidothiazole-4-yl]-2-(*syn*)-methoxy-imino acetic chloride in four steps. The melting point was determined, and IR spectral analysis and elemental analysis were performed to confirm cefotaxime structure. The quantitative determination was performed. **Results:** The reaction conditions were established. The yield of the synthesis phases (73-80%) and actual yield (45-47%) were very good. The structure of the obtained cefotaxime sodium salt was confirmed by the IR spectral analysis and by elemental analysis (C, H, N). The melting point was 163^0C. The purity of the synthesized cefotaxime sodium salt was 98.9%. **Conclusions:** Cefotaxime sodium salt was synthesized by acylation of 7-aminocephalosporanic acid with 2-[2`-chloracetamidothiazole-4-yl]-2-(*syn*)-methoxy-imino acetic chloride, in aqueous solution, then transformed into sodium salt with sodium 2-ethylhexanoate. The method proved to be very good, yields were good, it is reproducible and simple, and does not involve high risks, so it is also safe. **Keywords:** 7-AMINOCEPHALOSPORANIC ACID, CEFOTAXIME, CEPHALOSPORINS, ACYLATION.

Cephalosporins are often used to treat severe infections with Gram-negative and Gram-positive aerobic and anaerobic microorganisms (1). Cefotaxime is a third generation cephalosporin, being a broad spectrum beta-lactam antibiotic with high resistance to beta-lactamase inactivation. In therapeutic doses it has no toxicity, and it is used as antibacterial agent in severe infections caused by susceptible strains of Gram-positive and Gram-negative bacilli, Gram-positive and Gram-negative cocci. It is a parenteral cephalosporin used as "ex temporae" solution of cefotaxime sodium salt, 1-2 g/day every 8-12 hours. It can be used to treat severe infections in adults, children and infants (2).

Cephalosporins could be obtained by acylation of the 7-amino group of 7-amino cephalosporanic acid (7ACA) with acyl chlorides, mixed anhydrides, activated esters, activated acids, enzymatic acylation and transacylation (3, 4, 5, 6).

This paper presents the possibilities of acylating 7-aminocephalosporanic acid (7ACA) with an adequate acyl chloride in

order to obtain cefotaxime, a third generation cephalosporin.

MATERIAL AND METHODS

Apparata:

- Infrared Spectrophotometer UNICAM SP200;
- Melting point apparatus Mel-Temp Barnstead/Thermolyne 1002 (USA);
- Exeter-Analytical, CE-440 elemental analyzer with thermal conductivity detection.

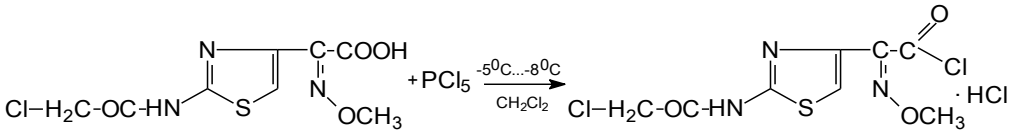
Materials and reagents:

7-aminocephalosporanic acid; 2-[2`-chloracetamidothiazole-4-yl]-2-(*syn*)-methoxy-imino acetic acid; thiourea; sodium 2-ethylhexanoate; phosphorus pentachloride; standard reagents and organic solvents (*p.a.* quality) purchased from Sigma Aldrich Company.

Chemistry

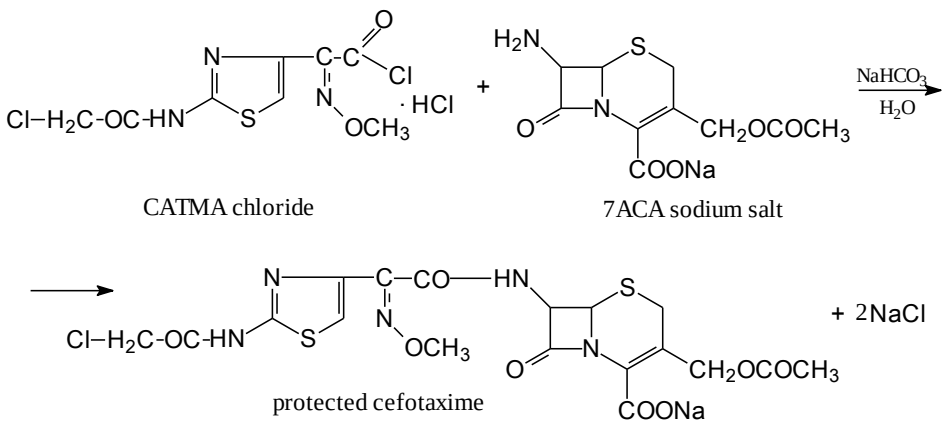
Cefotaxime sodium salt synthesis was performed in four steps:

1. 2-[2`-chloracetamidothiazol-4-yl]-2-(*syn*)-methoxy-imino acetic (CATMA) chloride obtained by treating the methylene chloride solution of the CATMA acid with phosphorus pentachloride at -5^0C (fig. 1);
2. 7ACA sodium salt acylation with CATMA choloride, obtained in the first step, at 10–15^0C, when a protected cefotaxime was formed (fig. 2);
3. deprotection of the second step obtained compound, by treating it with thiourea and then with formic acid untill pH=1.9–2.2 at -5^0C, when cefotaxime free acid was formed (fig. 3);
4. cefotaxime sodium salt obtained by treating the cefotaxime free acid with an isopropanol solution of sodium 2-ethylhexanoate (fig. 4).



CATMA acid CATMA chloride

Fig. 1. Synthesis of CATMA chloride



CATMA chloride 7ACA sodium salt

protected cefotaxime

Fig. 2. Synthesis of protected cefotaxime

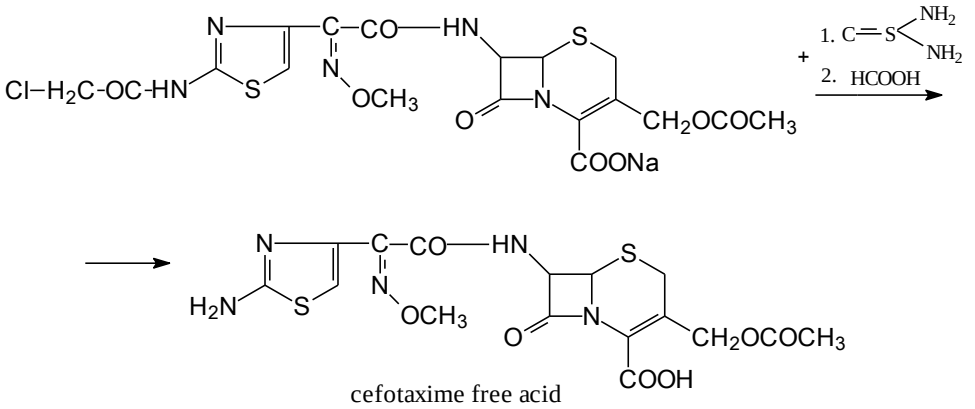


Fig. 3. Synthesis of cefotaxime free acid

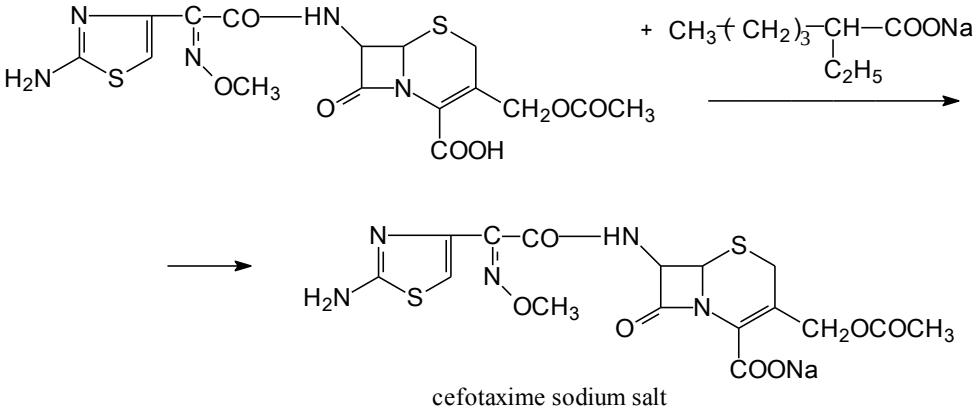

Fig. 4. Synthesis of cefotaxime sodium salt

In the first phase the CATMA chloride was obtained by treating the methylene chloride solution of the CATMA acid with phosphorus pentachloride at -5^{0}C…-8^{0}C. We suspended 5 g of 2-[2`-chloracetamido-thiazol-4-yl]-2-(*syn*)-methoxy-imino acetic acid in 125 ml of methylene chloride and cooled the suspension to -5^{0}C…-8^{0}C. Then, 5.8 g of phosphorus pentachloride were added, and after 30 minutes of stirring 63 ml of *n*-hexane were added. The suspension was filtered and the precipitate washed 2-3 times with *n*-hexane and then dried.

In the second phase, the 7ACA sodium salt was acylated with the previously obtained CATMA chloride. Four g of 7ACA acid were suspended in 72 ml of distilled water. The suspension was cooled to 10–15^{0}C and then 4.7 g of $NaHCO_3$ were slowly added. In 15–20 minutes a solution of 7ACA sodium salt was obtained. The CATMA chloride was slowly added and at

room temperature the acylation reaction was performed for 3 hours. The protected cefotaxime sodium salt was obtained.

In the third phase, the compound obtained in phase 2 was deprotected by treating it with thiourea and then with formic acid until pH=1.9–2.2 at -5^0C; cefotaxime free acid was formed. Over the solution obtained in phase 2, protected cefotaxime sodium salt, 2.8 g thiourea were added and stirred for 6 hours at room temperature. The solution was discolored with activated carbon charcoal and the suspension was filtered. The obtained filtrate was diluted with distilled water, cooled to -5^0C and acidulated with 80% formic acid solution until pH=1.9–2.2. The obtained suspension was filtered, and the precipitate was washed with cold water. The crystals were suspended in 95% ethanol, stirred for 2 hours, then filtered and dried for 3 hours at 25–40^0C.

In the fourth phase the cefotaxime sodium salt was obtained. The methanolic solution of cefotaxime (5 g of cefotaxime dissolved in 17 ml of methanol) was treated with stoechiometric quantities of isopropanolic solution of sodium 2-ethylhexanoate. The mixture was stirred for 10 minutes and then discolored with activated carbon, for other 10 minutes. The activated carbon charcoal was filtered and washed with methanol. After that, over 200 ml of isopropanol the cefotaxime sodium salt methanolic solution was added and the crystallization process of the cefotaxime sodium salt started. The suspension was stirred for 60 minutes and then filtered. The crystals were washed with 10 ml of isopropanol and dried.

The product was purified by recrystallization from 95% ethanol. The pure cefotaxime sodium salt was dried for 5 hours at 40–45^0C.

The IR spectra of the synthesized cefotaxime sodium salt and of the standard one were recorded with an Infrared Spectrophotometer UNICAM SP200. The spectra were acquired over the range of 650 and 5000 cm^{-1}. The elemental analysis was performed with an Exeter-Analytical CE-440. The quantitative determination of the synthesized cefotaxime sodium salt was carried out by titration in non-aqueous medium with perchloric acid in dioxane, according to pharmacopoeia (7, 8).

RESULTS AND DISCUSSION

Using the presented method we obtained cefotaxime sodium salt as a white, white-yellowish crystalline powder, with characteristic odor, bitter taste, and very slightly soluble in water.

The compound was characterized by melting point and elemental analysis (C, H, N) (tab. I).

TABLE I

Physicochemical characteristics of cefotaxime sodium salt

No	Substance	Molecular formula	Molecular weight	Melting point (^{0}C)	C, H, N calculated/ found (%)
1.	Cefotaxime sodium salt	$C_{16}H_{16}N_5NaO_7S_2$	Mr=477.45	163	C:40.24/40.18 H:3.37/3.34 N:14.66/14.61

The yields of the process phases were very good, over 70% for each phase, and also the overall yield of the general process was very good, over 45% (tab. II).

TABLE II
The yields of the process

Phase	**η (%)**			**η (%) average**
Phase 1	77.96	79.23	77.78	78.32
Phase 3	79.61	80.64	80.89	80.38
Phase 4	73.07	74.00	73.46	73.51
General process (overall yield)	45.35	47.27	46.21	46.27

These suggest that the method used to obtain cefotaxime sodium salt is a good one, is reproducible, and the obtained amounts are large. The method is easy to perform, is simple and does not involve high risks, so it is also safe.

The structure of the cefotaxime sodium salt obtained by the above described method was confirmed by IR spectral analyses and compared with the IR spectrum of cefotaxime sodium salt standard. The characteristic absorption bands of all functional groups were recorded (tab. III).

In the IR spectrum of the obtained cefotaxime sodium salt the characteristic absorption bands of all functional groups were observed. The presence of absorption bands at 1760 cm^{-1}, characteristic of CO lactonic group, proved the integrity of the β-lactam ring. The presence of absorption bands at 3320 cm^{-1} proved the presence of the free amine group in the 3-position of the thiazole ring.

The quantitative determination was done by titration in non-aqueous medium with perchloric acid in dioxane. In order to correspond to pharmacopoeia provisions, the obtained cefotaxime sodium salt must contain at least 98.0% and no more than 102.0% cefotaxime sodium salt related to the anhydrous substance (7, 8). The obtained cefotaxime sodium salt had a purity of 98.9%, so it meets the provisions of pharmacopoeia (tab. IV).

TABLE III
Characteristic spectral bands of cefotaxime sodium salt

Substance	**IR characteristic band (cm^{-1})**				
	-NH-	**-CO- lactonic**	**-CO- amidic I**	**-CO- amidic II**	**-C=N- thiazolic**
Synthesized cefotaxime sodium salt	3320	1760	1650	1540	1730
Cefotaxime sodium salt standard	3350	1770	1660	1540	1730

TABLE IV

Cefotaxime sodium salt concentration

No.	Substance	Concentration (%)
1.	Cefotaxime sodium salt	98.9

CONCLUSIONS

In this study we synthesized cefotaxime sodium salt by acylation of 7ACA sodium salt with CATMA chloride, in aqueous solution, when cefotaxime free acid was formed, followed by the transformation in sodium salt with sodium 2-ethylhexanoate.

The method proved to be a very good one, having good yields, is reproducible, and the obtained amounts are large. It is not difficult to perform, is simple, and does not involve high risks, so it is safe.

IMPORTANCE OF SULFONAMIDE MOIETY IN CURRENT AND FUTURE THERAPY (Abstract): Sulfonamides and their different derivatives are extensively used in therapy due to their pharmacological properties. Sulfa drugs were amongst the oldest synthesized antimicrobial agents and are still widely used today to treat different microbial infections. Clinical treatment with sulfonamides has regained confidence with the use of a combination of sulfamethoxazole and trimethoprim to treat urinary tract bacterial infections. Today, they are widely used as antimicrobial agents, chiefly because of their low cost, low toxicity and excellent activity against bacterial diseases. Over the course of time, the application of sulfonamides has been extended from their use as antimicrobial agents to anticancer agents, antiglaucoma agents, inhibitors of γ-secretase, cyclooxgenase-2 and lipoxygenase, anticonvulsivant agents, hypoglycemic agents. **Keywords:** SULFONAMIDES, ANTIMICROBIAL, LOW TOXICITY.

The introduction of sulfonamides in 1935 marked a turning point, a true „therapeutic revolution", and opened the era of ''miracle drugs''. After the discovery of penicillin followed by other antibiotics sulfonamides became less used, but later they started to attract attention for their synergic activity in the combination with trimethoprim.

Sulfonamides proved to be the starting point for a series of structural changes and this has led to the discovery of new drugs or classes of drugs used today not just in combating bacterial infections, but also in other diseases. They have widespread use in a variety of applications including antibacterials, antitumor agents, diuretics, carbonic anhydrase inhibitors, hypoglycaemic agents, thyroid inhibitors, and protease inhibitors (1). In recent years, molecules containing sulfamide group have also been investigated as inhibitors of ATP-sensitive potassium channels, carboxy-peptidase A, γ-secretase, glycosidase, HCV polymerase (NS5B), HIV-1 integrase, HIV-1 protease, histone deacetylase, human chymase, human leukocyte elastase, kinesin spindle protein, monoamine reuptake, plasma cell membrane protein-1, and thrombin; as agonists of androgen receptor, β_3-andrenergic receptor, and as antagonists of CXCR2 (2).

The chemical class of sulphonamides shares a common sulfanilamide moiety with

an aromatic amino group at the C_4-position, differing in the substitution of sulfamoil group at the C_1-position. A tetrahedral sulfur atom and multiple vectors for substitution of the nitrogen atoms lead to conformational and structural diversity (fig. 1).

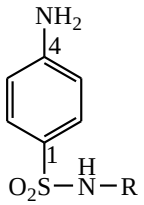

Fig. 1. The backbone of the sulphonamides

The characterization of sulfonamides as chemotherapics is more than half a century old. Since then, the sulfonamide group -*SO_2NH*- has been found as a key structural motif shared by a large number of bioactive compounds, spanning a wide variety of biological effects, such as antimicrobial activity, specific enzyme inhibition, hormone regulation, among others. They are usually classified as short-acting sulfonamides, with half lives (in serum) of 5–10 hours (i.e. sulfisoxazole, sulfadiazine and sulfamethizole); intermediate-acting sulfonamides, with half lives of 10–12 h (i.e. sulfamethoxazole, sulfadimethoxine and sulfamethazine); and finally long-acting sulfonamides, with half lives from 40 h onwards (i.e. sulfadoxine and sulfamethoxypyridazine) (3). Sulfadiazine and more recent compounds, including sulfafurazole (sulfisoxazole), sulfa-methoxazole, sulfametrole, sulfacitine and sulfamethizole, are quickly absorbed and eliminated. Compared with the older generation they are more soluble, less toxic, and probably less allergenic. Long-acting sulfonamides include sulfametoxydiazine, sulfadimethoxine, and other compounds, of which many are no longer available, due to the fact that they were associated with severe hypersensitivity reactions.

SULFONAMIDES AS ANTIVIRAL AGENTS

The effectiveness of sulfonamides has also been proven over time in the context of viral infections. A large number of structurally novel sulfonamide derivatives have ultimately been reported to show substantial antiviral activity *in vitro* and *in vivo*. Hepatitis C virus (HCV) is a common pathogen that can lead to cirrhosis, hepatocellular carcinoma (HCC), and liver failure. It is estimated that 170 million people were infected worldwide by the year 2000, and that the virus is responsible for at least 10.000 deaths annually in the United States alone. Moreover, existing therapies are hampered by drug-related toxicities. Therefore, there is a particular need for new therapies directed to genotype 1 HCV infection. An attractive strategy for the treatment of liver infection with hepatitis C virus was the synthesis of some compounds with sulfonamidic structure (4). On the other hand, Delavirdine (Figure 2), a second-generation bis(heteroaryl) piperazine, is licensed for the treatment of HIV infection and it is used in combination with other anti-HIV agents (5).

SULFONAMIDES AS ANTIBACTERIAL AGENTS

They are used in urinary tract infections, meningitis, streptococcal pharyngitis, bacillary dysentery, trachoma, chancroid, malaria, toxoplasmosis, nocardiasis, and conjunctivitis. The most popular sulfonamides are p-aminobenzensulfonamides, or sulfanilamides, which are bacteriostatic due to their resemblance to p-aminobenzoic acid (PABA), used by bacteria in the biosynthesis of folic acid required for their growth (6). They interfere with the use of *p*-aminobenzoic acid (PABA) in the bio-

synthesis of tetrahydrofolic acid, which is a growth factor that is vital for bacterial metabolism. Sulfonamides have a wide range of antimicrobial activity against both *Gram-positive* and *Gram-negative* bacterial strains. These drugs act on the bacteria themselves and either prevent their growth (bacteriostatic) or act as germicides (bactericides).

The topical use of sulfonamides has been limited, because of the high risk of hypersensitivity.

Nevertheless, sulfacetamide and sulfadicramide are still used topically for eye infections.

Because systemic antibiotics are ineffective in reducing bacterial counts in granulation wounds, the use of a suitable topical antibacterial agent may substantially decrease wound sepsis and benefit overall management. The actions of topical 1% silver sulfadiazine and of topical 5% mafenide acetate in *Acinetobacter strains* wound infection have been investigated (7). Metal-based drugs for the treatment of many ailments have gained much attention over the last decade. The ability of metal ions to bind *in vivo* with proteins and peptides is an important feature of metal-based drugs. Simple and *N*-substituted sulphonamides have attracted much attention in this context. Modified toxicological and pharmacological properties have been observed when some of these sulphonamides are administered in the form of their metal complexes. For example, Ag(I)-sulfadiazine, Ce(III)-sulfadiazine, Ni(II)-sulfadimethoxine and Cu(II)-sulfacetamide have shown higher antimicrobial activity than free ligands. Several authors have conductingstudies on the coordination forms of sulphonamides with Cu (II), reported the versatility of these ligands and the importance of their complexes in coordination chemistry (8). Some sulphonamide complexes have proved to be relevant catalysts in chemical reactions, such as Zn-sulfonamide complexes that catalyze enantio selective cyclopropanations, and also reagents for the cleavage of nucleic acids. On the other hand, numerous sulphonamide complexes have been studied as simple models of metal-protein interactions. In addition, some metal sulfonamides have drawn much attention due to the fact that they are mainly used in medicine as antibacterial drugs (9).

Sulfonamides and their different derivatives are among the most widely used antimicrobial agents, chiefly because of their low cost, low toxicity and excellent activity against bacterial diseases.

SULFONAMIDES AS ANTICANCER AGENTS

Among the wide range of compounds tested as antitumor agents, sulphonamides have attracted great attention, as many sulphonamide derivatives were reported to have interesting antitumor activity.

Recently, it has been showed that β-carbonic anhydrase from *Mycobacterium tuberculosis*is inhibited by several sulfonamides at low concentration. Sulfa methoxazole was shown to inhibit dihydropteroate synthase of *Mycobacterium avium* and affected the growth of three strains of *Mycobacterium avium* complex with MIC50/80 about 30 mg/mL. Also other sulfonamides were active against *Mycobacterium avium* complex (10).

There are a variety of mechanisms for their anticancer action, such as disruption of microtubule assembly, cell cycle arrest in the G1 phase, functional suppression of the transcriptional activator NF-Y, angiogenesis and carbonic anhydrase inhibition (11). The most prominent of these mechanisms was the inhibition of carbonic anhydrase isozymes (12). It has been shown that

two carbonic anhydrase isozymes (CA IX and CA XII) are prominently associated in many tumors. They are involved in crucial processes associated with cancer progression and response to therapy. Aromatic or heteroaromatic sulfonamides have been shown to reverse the effect of tumor acidification; consequently they inhibit the growth of cancer cells and supress carbonic anhydrase-mediated tumor invasion (13).

Methanesulfonamides ($CH_3SO_2NH_2$) are also used in drug industry because of their biological activity on a large scale. Methanesulfonamide derivatives have DNA binding ability, show cytostatic effects, and some of them, such as Amsacrine (Fig. 2), are used in cancer chemotherapy. In addition, some sulfonyl hydrazines are known to have antineoplastic effects which prevent malignant cells growth and spread (14).

SULFONAMIDES AS ANTIGLAUCOMA AGENTS

Several sulfonamides, such as acetazolamide, methazolamide, ethoxzolamide or dichlorophenamide, are clinically used as systemic antiglaucoma agents for more than 50 years. In the mid 90s, the first clinically used, topically effective antiglaucoma sulfonamide, dorzolamide, was discovered (15). More recently, another topically acting antiglaucoma sulfonamide is also available: brinzolamide (Figure 2). However the main drawback of these compounds, and of many sulfonamides reported so far in the literature, is their lack of selectivity, as they usually inhibit most of the catalytically active isoforms of carbonic anhydrase in the low nano/ micromolar range (16).

SULFONAMIDES IN ALZHEIMER'S DISEASE

Furthermore, recent studies suggest that carbonic anhydrase activation may provide a novel therapy for Alzheimer's disease (17), the most prevalent form of dementia that affects approximately 24 million people worldwide. A number of structurally diverse γ-secretase inhibitors have been reported and several advanced into clinical trials. Recently, the structure–activity relationships of a series of N-bridged bicyclic sulfonamides as inhibitors of γ-secretase have been reported (18). Begacestat (Fig. 2) is a novel thiophene sulfonamide gamma-secretase inhibitor that selectively inhibits cleavage of amyloid precursor protein (APP) (19).

SULFONAMIDES AS ANTICONVULSANT AGENTS

A new class of anticonvulsant structures that belong to the family of sulfamides has been designed. In recent years, several compounds, such as topiramate and zonisamide (Fig. 2) have been approved as anticonvulsant drugs. Their anticonvulsant action is probably due to CO_2 retention secondary to inhibition of red cell and brain carbonic anhydrase enzyme, but other mechanisms of action, such as sodium channels blockade were proved for some of them (20).

SULFONAMIDES AS COX-2 AND LIPOXYGENASE INHIBITORS

Sulfasalazine (salicylazosulfapyridine), a compound in which sulfapyridine is linked to 5-aminosalicylate by a diazo bond has been and still is widely used to treat ulcerative colitis and regional ileitis (Crohn's disease). Sulfasalazine is not used for the antibacterial properties of the sulfapyridine, but for the local anti-inflammatory effect of 5-aminosalicylate. Selective cyclooxygenase-2 inhibitors (COX-2) (Celecoxib, Parecoxib, Valdecoxib) are compounds with sulfonamide struc-

ture that are indicated for the relief of signs and symptoms of osteoarthritis and rheumatoid arthritis but also for the treatment of primary dysmenorrhea.

Recently, sulfonamide group has been found to be the key constituent of a new class of compounds as potential inhibitors of lipoxygenase (21), enzyme that catalyzes the oxidation of polyunsaturated fatty acids.

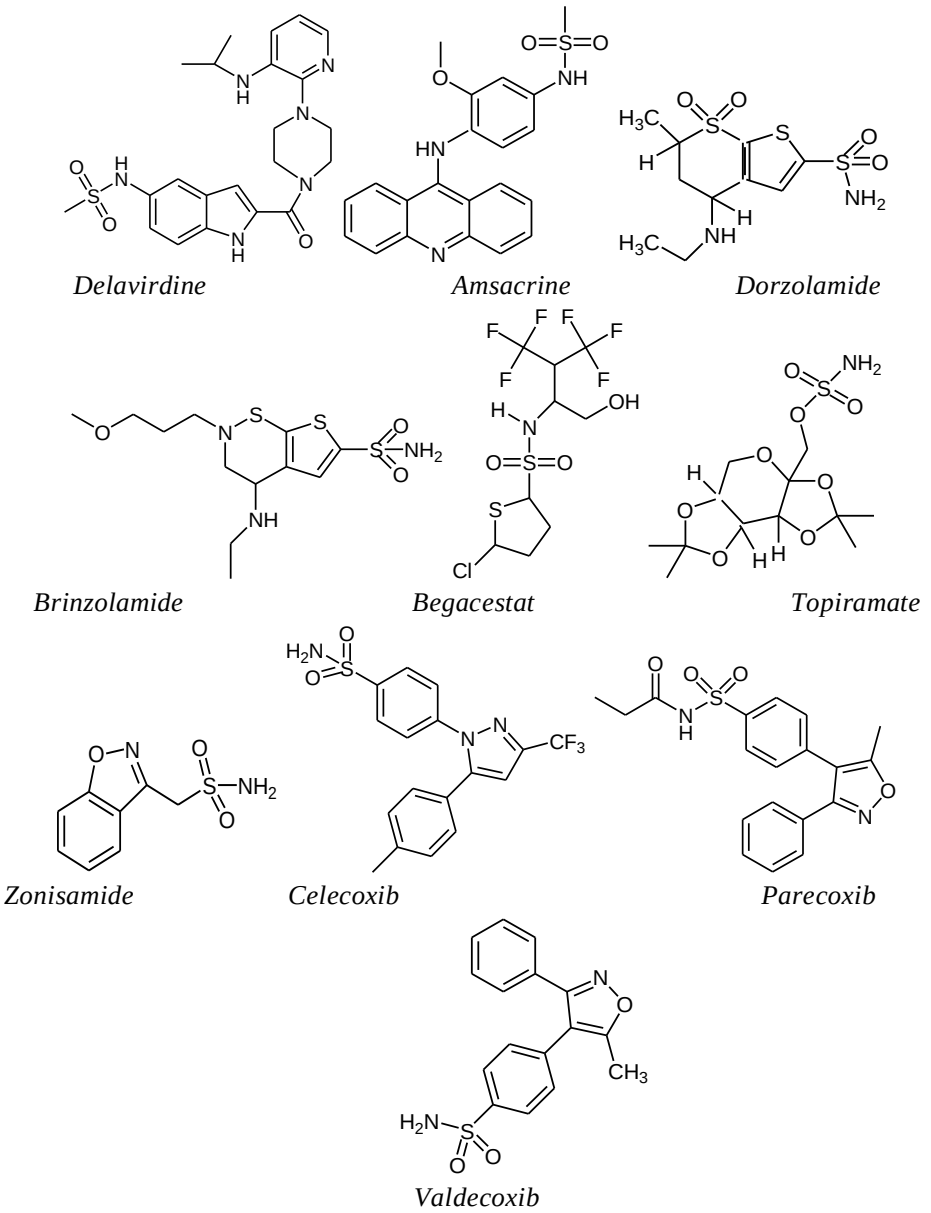

Fig. 2. Drugs with sulfonamide structure

SULFONAMIDES AS HYPOGLYCEMIC AGENTS

Sulfonylureas are known to act by closing the adenosine triphosphate-sensitive potassium (KATP) channels in the pancreas through binding to the sulphonylurea receptor (SUR) 1 (an integral component of pancreatic KATP channels), leading to beta cell insulin release. The beta cells of patients taking these drugs are chronically stimulated. Sulfonylureas have been regarded as being unsuitable for overweight diabetics, who primarily need to lose weight. However, KATP channels are also found in coronary vascular smooth muscle cells and cardiomyocytes, but here the SUR components are of the SUR 2A and SUR 2B subtypes, respectively (22).

OTHER APPLICATIONS OF SULFONAMIDES

Today, one of the most widely used sulfonamide drugs is *sildenafil*, marketed as Viagra®. It is a drug used to treat erectile dysfunction and pulmonary arterial hypertension by inhibiting cGMP specific phosphodiesterase type 5, an enzyme that regulates blood flow in the penis. Sildenafil, as a selective PDE5 inhibitor, inhibits cGMP degradation and improves the relaxation of the smooth muscles in the corpus cavernosum (23).

CONCLUSIONS

Compounds with sulfonamide structure enjoy a vast applicability. In this context, they have been widely studied for many years, for their chemotherapeutic activity. The application of sulfonamides has greatly been extended over the years from their function as antimicrobial agents to COX-2 inhibitors, diuretics, carbonic anhydrase inhibitors and even as an anti-impotence drug. In conclusion, sulfonamides represent a diverse and relevant class of therapeutic drugs. The sulfonamide group remains a important strating point for the discovery of new compounds to treat an increasing portfolio of diseases.

RESEARCH STUDIES ON THE QUALITY OF BIO-MUCOADHESIVE TABLETS CONTAINING MICONAZOLE NITRATE

Magdalena Bîrsan,[1] Iuliana Popovici [2], Laura Palade [1], Ileana Cojocaru [2]
University of Medicine and Pharmacy "Grigore T. Popa" – Iasi

1. Ph.D. student
2. Discipline of Pharmaceutical Technology

RESEARCH STUDIES ON THE QUALITY OF BIO-MUCOADHESIVE TABLETS CONTAINING MICONAZOLE NITRATE (Abstract): Biomucoadhesive tablets are widely used to formulate topical antifungal drugs for treating acute oral candidiasis. The research focuses on the pharmaco-technological control of certain bio-mucoadhesive tablets containing miconazole nitrate, formulas developed and prepared by the authors based on the original formulas. The analyzed parameters were: macroscopic aspect, physical-chemical (pH) and pharmacotechnical properties (hardness, friability, mass uniformity, in vitro disintegration).The used methods are described in literature, most of them included in the Romanian and European Pharmacopoeia. The obtained results allow us to conclude that of the five original formulas, two (formulas IV and V) meet the criteria for oral mucosa drug by their tolerance (pH 5.77 to 5.84) and retention time (65-90 min.), the intimate contact of the tablet with the oral mucosa determining a high concentration of active substance. **Keywords**: MICONAZOLE NITRATE, BIOMUCOADHESION, ORAL BIOADHESIVE TABLETS.

During the last years, bioadhesive tablets have been developed to improve oral drug bioavailability. Drug administration through epithelial routes avoids first-pass effect (or presystemic metabolism), is safe and efficient (1-3). Oral cavity is a convenient area for placing them and is well-accepted by users. Five formulas of bio-mucoadhesive tablets containing miconazole nitrate in a concentration of 0.25 g have been developed and analyzed (4). Quality control of the obtained biomucoadhesive tablets was done by macroscopic, physical-chemical (pH) and pharmacotechnical (hardness, friability, mass uniformity, *in vitro* disintegration) tests.

MATERIAL AND METHODS

Five formulations of mucoadhesive tablets containing miconazole nitrate in a concentration of 0.25 g were prepared and evaluated using quality control tests:

Macroscopic Characteristics: the following visual and olfactory characteristics have been analyzed: aspect, uniformity, colour, smell, taste, shape and size.

Tablets Size: diameter (d2) and height (h) were determined using PHARMA-TEST equipment, Germany. Tablet area calculation was done by the formula:

$$S = \frac{\pi * d^2}{4}$$, where: S- tablet area (mm^2). r - tablet radius (mm).

Mass Uniformity was determined according to FR X and Eur. Ph. on a BD 202 Mettler Toledo analytical balance.

Tablets Hardness was determined by using PHARMA TEST equipment (Germany), the average value for 10 tablets from each formulation batch being obtained.

Tablets Friability for exposing tablets to rolling and vibration was analysed by using a ROCHE brittling machine. Friability was calculated by using the formula:

Friability = Lost Mass/Initial Mass x 100

The procedure consists in weighing 10 tablets that are tumbled in the brittling machine. The unit was set at 100 RPM for 4 minutes.

Tablet pH. The pH value of the biomucoadhesive tablets containing miconazole nitrate was obtained by potentiometric analysis (Cyberscan 2500 with pH electrode using data fitting software)

Disintegration Time of tablet was determined using method B from Romanian Pharmacopoeia 10th edition. Disintegration test was carried out on 6 tablets of each formula in a glass with 500 ml distilled water at a temperature of 37°C ± 2ºC.

For processing the experimental data, we used the descriptive statistics of the ANOVA analysis of variance.

RESULTS AND DISCUSSION

The resulting biomucoadhesive tablets have a lenticular disc shape, are flat, uniform, with full margins, flat, white, uniform surface, spotless and odourless.

The biomucoadhesive tablets are 8.99 mm in diameter and 2.75 mm in height, with small differences between the five formulations (tab. I, II).

The degree of asymmetry of distribution (skewness) around the mean, compared to the normal distribution, is represented by a frequency distribution:

- as an asymmetrical ”tail”, in the ”positive” values range for formulas I, III, IV, and V

- as an asymmetrical ”tail”, in the ”negative” values range for the IInd formula, explained by the presence in the tablet of CMC-Na 60 mg, and PEG 6000 40 mg.

TABLE I

The Physical Characteristics of Biomucoadhesive Tablets Containing Miconazole Nitrate

Formula	Bulk (h) (mm)	Diameter (mm)	Area $S = \frac{\pi * d^2}{4}$	Hardness (N)	Friability %	pH	Disintegration Time (min)
I	2.753 [1](0.0033)	8.988 [1](0,008)	63.447	60.06	0.9404	5.487	25
II	2.518 [1](0.008)	9.002 [1](0.002)	63.645	54.98	0.9268	5.500	45

Maximum	63.400	65.700	85.600	85.300	73.500
Sum	600.600	549.800	723.800	761.400	701.500
Count	10	10	10	10	10

Mass Uniformity. Compared to the calculated average mass, the individual mass agrees with percentage deviations provided by Romanian Pharmacopoeia 10th

edition (219 mg / tablet ± 7.5%).

Tablet Hardness. Tablet hardness values are shown in table I and statistical calculation in table III. The differences are explained by the polymers used in the formulas.

The degree of asymmetry of distribution (skewness) around the mean value, compared to the normal distribution, is represented as a frequency distribution:

- as an asymmetric"tail", in the "positive" values range for formula II;

- as an asymmetric"tail", in the "positive" values range for formulas I, III, IV, and V.

The degree of "flattening" of the distribution (Kurtosis), compared with the normal distribution, indicates a relatively flat curve for formulas I, III, IV and V (higher hardness for these four formulae) and a curve with a higher peak than the normal distribution, for formula II, that is a lower hardness for this formula.

Higher mechanical strength (hardness) values have been obtained for formulas III, IV and V.

Tablet Friability. Mechanical strength of the tablets (tab. IV) is unsatisfactory when a maximum limit of 1% is exceeded. Statistical calculation is shown in table IV.

TABLE IV

Tablet Friability (%). Descriptive Statistics

	Formula I	**Formula II**	**Formula III**	**Formula IV**	**Formula V**
Mean	0.9242	0.9268	3.0506	0.2376	0.6264
Median	0.926	0.925	0.717	0.22	0.449
Mode	0.881	0	0	0.044	0
Standard Deviation	0.045523	0.008385	3.319278	0.198244	0.244786
Standard Error	0,00041446	0,00001406	2,20352186	0,00786016	0,026306012
Sample Variance	0.002072	7.03E-05	11.01761	0.039301	0.05992
Kurtosis	-2.98068	0.276745	-3.32187	-3.00978	-3.323805
Skewness	0.015806	0.678451	0.606655	0.110428	0.610101
Range	0.093	0.022	6.271	0.396	0.455
Minimum	0.881	0.917	0.489	0.044	0.446
Maximum	0.974	0.939	6.76	0.44	0.901
Sum	4.632	4.633	15.253	1.188	3.132
Count	5	5	5	5	5

The degree of asymmetry of distribution (skewness) around the mean compared to the normal distribution is represented by a frequency distribution:

- as an asymmetrical"tail", in the "positive" values range for all the five formulas.

The degree of "flattening" of distribution (Kurtosis) compared with the normal distribution indicates a relatively flat curve for formulas III, IV and V (lower friability for the fourth formulas) and a curve with a higher peak than the normal distribution for formula, fact that implies a higher hardness for this formula.

The biomucoadhesive tablets with high hardness have low friability. After analysing the formulas, it can be noticed that formulas IV and V have friability less than 1%. Formulas IV and V have an adequate friability of 0.237% and 0.626, respectively.

pH. As seen in table I, pH values ranged between 5.487 and 5.840.

Disintegration time. The analysis of the results obtained following the disintegration of the five tablet-formulas containing miconazole nitrate (tab. V) revealed different disintegration times for the five tablet-formulas.

TABLE V

Disintegration Time (min.) of Miconazole Nitrate

Descriptive Statistics

	F I	F II	F III	F IV	F V
Mean	25.015	45.035	60.06	65.54	90.03666667

Median	25.015	45.035	60.06	65.54	90.04
Mode	25.01	45.03	60.05	65.08	90.05
Standard Deviation	0.005477226	0.005477226	0.010954451	0.503904753	0.016329932
Sample Variance	3E-05	3E-05	0.00012	0.25392	0.000266667
Kurtosis	-3.33333333	-3.333333333	-3.33333333	-3.333333333	-0.3
Skewness	6.66134E-17	2.91887E-12	1.45943E-12	-6.34826E-14	-0.85732141
Range	0.01	0.01	0.02	0.02	0.04
Minimum	25.01	45.03	60.05	65.08	90.01
Maxi-mum	25.02	45.04	60.07	66	90.05
Sum	150.09	270.21	360.36	393.24	540.22
Count	6	6	6	6	6

Faster disintegration was recorded for formula I (25 min.), while formulas II, III, IV and V have very long disintegration times (45 min., 60 min., 65 min. and 90 min, respectively).

The long disintegration time of formulas II, III, IV and V is explained by the CMC-Na and miconazole nitrate polymer ratio, which is: 0.6: 0.25 for formula II and 1.00: 0.25 for formulas III, IV and V.

CONCLUSIONS

This study deals with the five formulas of miconazole nitrate biomucoadezive tablets developed by the authors, such as statistical analysis, proved that these formulas meet the quality requirements regulations regarding macroscopically characteristics, hardness, friability, mass uniformity, pH, and disintegration. The obtained data and especially the long disintegration time recommend formulas IV and V for further studies.

SILIBININ - PROTECTIVE ACTIVITY AGAINST *STAPHYLOCOCCUS AUREUS* PNEUMONIA

Staphylococcus aureus, a virulent Gram-positive pathogen, is responsible for nosocomial and community-acquired diseases which threaten human health such as soft tissue infections, septicemia and pneumonia. In the last decade, the emergence of methicillin-resistant *S. aureus* challenged the potency of traditional antibiotics, imposing major restrictions on the treatment options of *S. aureus* pneumonia. Recent reports have established and demonstrated in animal models that α-toxin plays a key role in the pathogenicity of staphylococcal pneumonia. Silibinin is the main biologically active ingredient in silymarin, a flavonolignan complex extracted from *Silybum marianum* fruits. Silibinin is known for its anti-inflammatory, antioxidant, hepatoprotective and anticancerigenic activity. This study shows that silibinin inhibits the expression of α-toxin in a dose-dependent manner and alleviates α-toxin-induced lung cells injury. Moreover, silibinin provides effective protection on the lung injury of staphylococcal pneumonia. Therefore, silibinin may potentially be used in combination with β-lactam antibiotics to treat *S. aureus* infections (Wang X, Dong J, Dai X, Zhang Y, Wang J, Li H, Lu C, Tan W, Gao X, Deng X, Bu S, Niu X. Silibinin *in vitro* protects A549 cells from *Staphylococcus aureus*-mediated injury and *in vivo* alleviates the lung injury of staphylococcal pneumonia. *Planta Med* 2013; 79: 110–115).

CONTRIBUTION OF CERTAIN INDIVIDUAL FACTORS AND OF THE ENTOURAGE TO THE HEAVY SMOKER STATUS IN TIMIS COUNTY STUDENTS

Mihaela Popa, R. Bagiu, Brigitha Vlaicu
"Victor Babeş" University of Medicine and Pharmacy, Timişoara, Romania

CONTRIBUTION OF CERTAIN INDIVIDUAL FACTORS AND OF THE ENTOURAGE TO THE HEAVY SMOKER STATUS IN TIMIS COUNTY STUDENTS (Abstract): The study aimed for a hierarchy of factors associated to the heavy smoker status in young people. **Material and methods**: The representative sample of students included into the study totalized 2076 young subjects in Timis County universities, with urban residence, 62.5% girls and 37.5% boys, aged between 18-25 years. The working method was the transversal population study based on the CORT 2004 questionnaire regarding health risk behaviors in adolescents and young people. Data processing used the *EpiInfo* software. The strongest predictors of the heavy smoker status in young people are the existence of suicidal thoughts, the increased number of friends who smoke the smoker status without the wish to quit. **Results and conclusions**: Students with an increased intensity of smoking more frequently experienced suicidal thoughts as compared to students smoking with a medium intensity. Students with a medium smoking intensity have significantly more friends who smoke as compared to students who are light smokers. Students, who tried to quit smoking, smoke significantly less cigarettes a day than those who did not wish to quit smoking**.** **Keywords**: STUDENTS, HEAVY SMOKER STATUS, ASSOCIATED FACTORS

In a study conducted in New Zealand (1), the authors demonstrated that early tobacco consumption was a important predictor for suicidal ideation but lost significance when increased levels of stress and depression, as well as low attachment for parents, were included into the multivariate model.

The affiliation of adolescents and young adults with friends who practice risk behaviors, especially substance consumption, is a strong predictor for the adherence to such behaviors (2, 3). The smoking habit in friends and the perception of smoker friends are associated to the smoking behavior in adolescents (4, 5, 6).

Individuals who cease smoking benefit from a significant decrease of the risk for all fatal disturbances (7). There is a clear relation between the age when a smoker quits and the risk of premature death. While smoking cessation has benefits over the general mortality, the benefit degree varies depending on the disease (8).

MATERIAL AND METHODS

The representative sample of Timis County students totalized 2976 young subjects from Timis County universities, urban residents (the size of the stratified cluster sample was determined with the the *EpiInfo* software). The gender distribution

was: 62.5% girls and 37.5% boys. The students were aged between 18-25 years, the highest proportion being aged 21 years, 27.2%.

The working method was the transversal population study based upon the CORT 2004 Questionnaire regarding health risk behaviors in adolescents and young people, designed on the occasion of the type A CNCSIS grant, code 1167, 2003-2005, entitled: "Assessment of the dimensions of risk behaviors in high school pupils and young subjects in undergraduate, postgraduate, occupational and university teaching systems in Timis County". The CORT 2004 Questionnaire represents an original working instrument belonging to the research team of the project and it was built upon other questionnaires used for the investigation of risk behaviors, mainly the European ESPAD and the American YRBSS. The Questionnaire was validated by the Commission of Ethics of the "Victor Babeş" University of Medicine and Pharmacy Timişoara, Romania.

High school pupils were only included into the study after freely expressed informed consent was obtained from each participant. The general response rate in students was 40%. Data processing and interpretation used advanced modern methods of medical statistics, with the *EpiInfo* software, version 3.5.1, 2008.

RESULTS AND DISCUSSION

1. The heavy smoker status. The logistic regression test was applied to determine the impact of multiple personal and entourage-linked factors on the heavy smoker status (high intensity smoking means over 10 cigarettes/day) in young people. The model includes 19 independent variables (gender, last school graduated by the father, last school graduated by the mother, satisfaction concerning the financial situation of the family, number of friends who smoke, number of friends who get drunk, number of friends who consume marijuana, smoking status of the father, mother and siblings, number of days he/she skipped classes, school grades, age when he/she smoked the first cigarette, the wish to quit smoking, number of days of binge drinking, marijuana consumption, feelings of sadness, suicidal thoughts, knowledge on the effects of smoking). The model including these predictors is statistically significant, $\chi^2(19)=110.36$, $p<0.001$, showing that the proposed model may discriminate between young people who smoke and those who do not. The model may explain between 21.7 and 30.0% of the heavy smoker status variance and may correctly classify 73.8% of the cases (tab. I).

The strongest predictor of the heavy smoker status in young people is the presence of suicidal thoughts, those reporting these thoughts having 2.18 times more chances to be high intensity smokers. The increased number of friends who smoke is an important predictor, young people with a high number of smoker friends having 2.1 times more chances to smoke with high intensity than those without friends who smoke, provided the other factors in the model are constant. The smoker status without the wish to quit is also an important predictor, young people who do not have the wish to cease smoking having 1.7 times more chances to smoke with increased intensity. The other statistically significant predictors are: the increased number of friends who smoke marijuana, the high number of days he/she skipped school, the non-smoker status of the mother and the female gender.

Legend: (1)= first category that was taken as reference to categorical variables introduced in the model; B= β coefficient; SE= standard error of the β coefficient; Wald= Wald coefficient; df= degrees of freedom; Sig.= p value; OR=odds ratio

The strongest predictor of the heavy smoker status in young people is the presence of suicidal thoughts, those reporting these thoughts having 2.18 times more chances to be high intensity smokers. The increased number of friends who smoke is an important predictor, young people with a high number of smoker friends having 2.1 times more chances to smoke with high intensity than those without friends who smoke, provided the other factors in the model are constant. The smoker status without the wish to quit is also an important predictor, young people who do not have the wish to cease smoking having 1.7 times more chances to smoke with increased intensity. The other statistically significant predictors are: the increased number of friends who smoke marijuana, the high number of days he/she skipped school, the non-smoker status of the mother and the female gender.

2. Suicidal thoughts during the previous year. In the non-smoker group 7.3%

(102) students experienced suicidal thoughts during the previous year. In the smoker group, the percent of students with suicidal thoughts is 10.2% (65). The smoker group had 1.42 times more frequent suicidal thoughts during the previous year as compared to the non-smoker group, χ^2=4.61, p<0.05 (fig. 1).

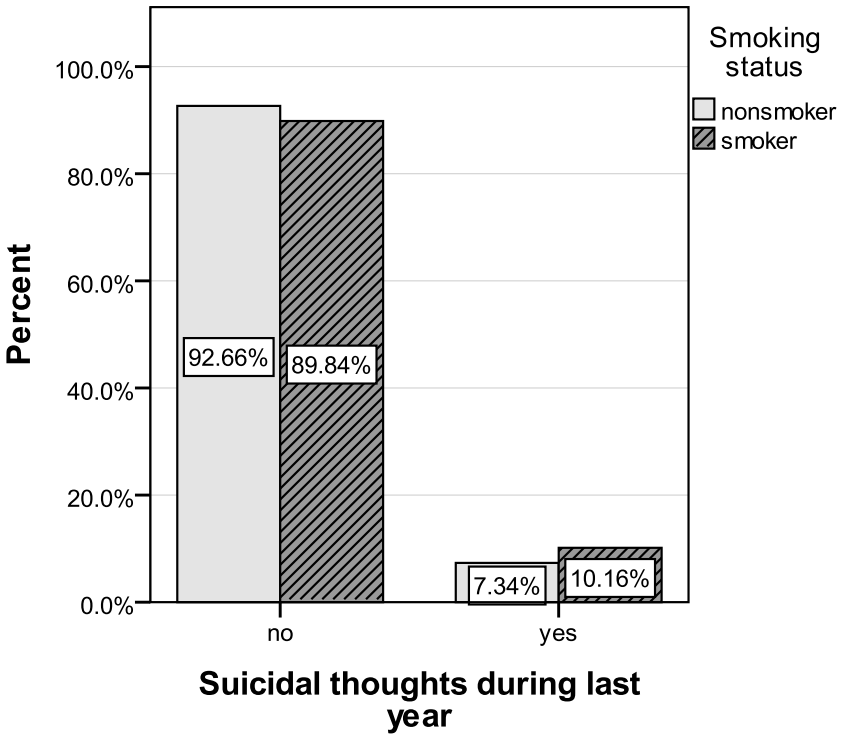

Fig. 1. Percent distribution of students according to the existence of suicidal thoughts and to the smoker status

Researchers conducted by Choi et al. (9) revealed that persons without depression and who did not smoke increased their chances to develop depression if they started smoking. Further studies (10) found that smoker adolescents and those who were ex-smokers at the beginning of the study had 1.5-2 times higher chances to develop depression symptoms in the future as compared to non-smokers.

3. Smoking among friends. Of the friends of non-smoker students, several smoke in a percent of 56.5% (787), most of them smoke in a percent of 31.1 (433) and all of them in a percent of 3.3 (46). 9.1% (127) of the non-smoker students have no friends who smoke. Of the friends of smoker students the majority smoke in a percent of 63.3 (407), several in a percent of 26.0 (167) and all in a proportion of 9.2% (59).

1.6% (10) of the smoker students has no friend who smokes. Smoker students have significantly more friends who smoke as compared to non-smoker students, U=267197, z=-16.11, p<0.001, the association being of medium size (fig. 2).

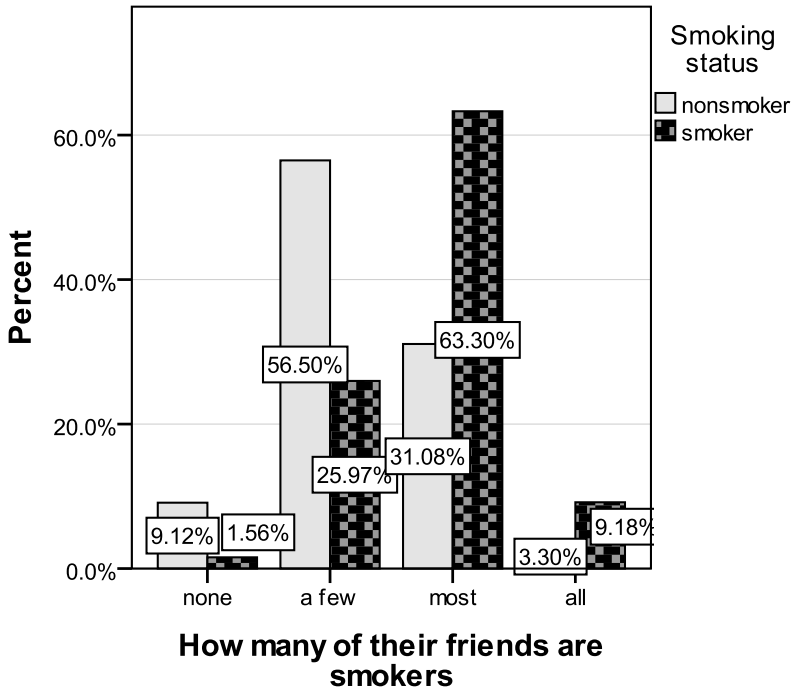

Fig. 2. Percent distribution of students according to the smoker status of friends and to their own smoker status

Regarding the non-smoker students, we found that smoking intensity is influenced by the number of friends who smoke, $H(2)=37.26$, $p<0.001$. We applied the Mann-Whitney test to investigate this result. We applied the Bonferroni correction and the effects were reported to a level of significance of 0.0167. We found that students with a medium smoking intensity have significantly more friends who smoke, as compared to light smoker students, $U=15342.5$, $z=-4.07$, $p<0.001$, and there are no differences between students who smoke with medium or high intensity regarding the number of friends who smoke (fig. 3).

The similarity or homogeneity of tobacco consumption patterns in adolescents and their peers, led researchers to the conclusion (6, 11) that the entourage of friends influences the smoking habit in adolescents. The most often incriminated mechanism is social learning (12), by which adolescents learn about the use of tobacco by observing friends who smoke and they are encouraged to use tobacco by perceiving apparent advantages such as gaining group acceptance or establishing an apparent social identity. Other transmission mechanisms from friends are direct pressure to smoke and offering cigarettes and other tobacco products.

4. Attempt to cease smoking. Regarding the attempt to cease smoking, 25% (513) of respondents admit they tried to quit smoking and 9.1% (186) did not try to quit smoking (fig. 4).

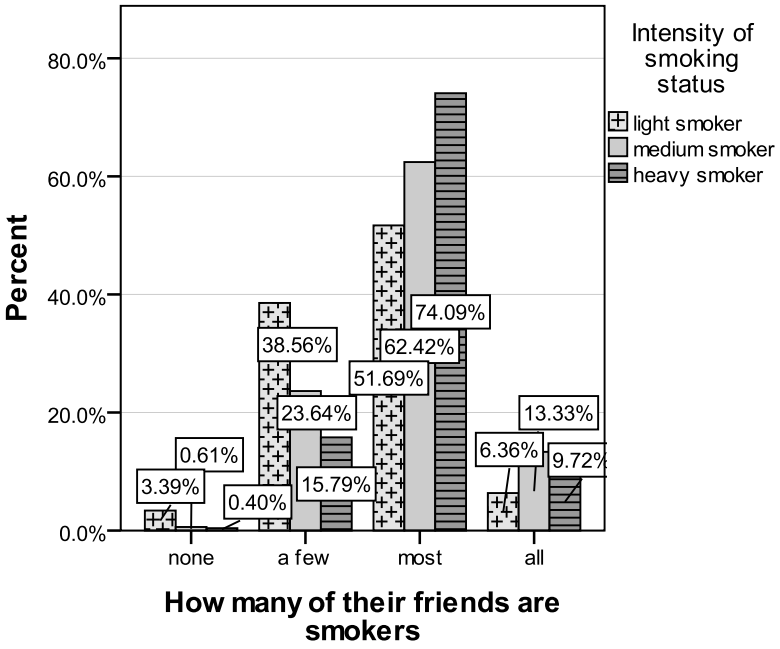

Fig. 3. Percent distribution of smoker students according to the number of friends who smoke and to the intensity of smoking

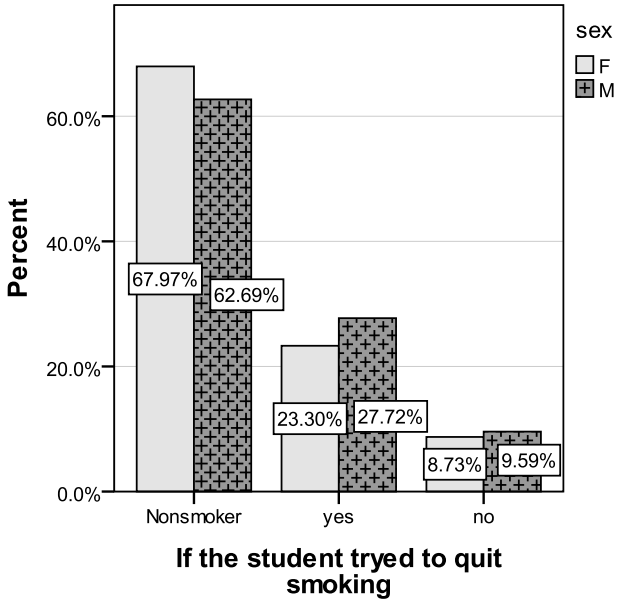

Fig. 4. Percent and gender distribution of students according to their attempt to quit smoking

After excluding the students who do not smoke, we wanted to find out if there were gender differences regarding the attempt to quit smoking. There are no significant differences in the distribution of gender related responses, $p>0.05$.

Using only the smoker students, we found out that those who tried to quit, smoked their first cigarette at a significantly older age than those who did not try to quit smoking, $U=38623$, $z=-4.08$, $p<0.001$. These results are concordant to other studies (13), concerning the fact that young age at the onset of smoking is associated to the permanent smoker status at adult age.

Naive smoking experiments in adolescents frequently transform them into regular users, frequently causing a strong addiction which counteracts smoking cessation efforts. Efforts to reduce smoking in future adults must focus on experimental as well as on regular smoking.

In smoker students, we found that those who tried to quit, smoke significantly less cigarettes a month than those who did not wish to cease smoking, $U=38931$, $z=-4.13$, $p<0.001$. Using only smoker students, the results showed that those who tried to cease smoking, smoke significantly less cigarettes a day than those who did not wish to cease smoking, $U=36473$, $z=-4.77$, $p<0.001$.

Previous research (14, 15) demonstrated that the earlier individuals start smoking the higher are their chances to develop pulmonary carcinoma or to have an altered health during adult life. Globally, one third of the young people who become regular smokers to adult age will die due to consequences of smoking (16). There is evidence that sometimes smoking is the first step to triggering the abuse of other substances, and preventing or delaying this first step will decrease the risk for the use of other substances (17-19).

CONCLUSIONS

The strongest predictors of the heavy smoker status in young people are the existence of suicidal thoughts, the increased number of friends who smoke the smoker status without the wish to cease smoking.

In non-smokers / smokers we obtained the following results: 7.3% / 10.2% of the students had suicidal thoughts during the previous year. Students who smoke at high intensity more frequently experienced suicidal thoughts as compared to medium intensity smokers.

The friends of non-smoker / smoker students also smoke: several in 56.5% / 26% of cases; most in 31.1% / 63.3%; all in 3.3% / 9.3%. Students who smoke with medium intensity have significantly more friends who smoke as compared to light smoker students.

Depending on the attempt to cease smoking, 25.0% of respondents tried to cease smoking and 9.1% did not. Students, who tried to cease smoking, smoke significantly less cigarettes a day than those who did not wish to quit.

DIAGNOSIS OF MENINGOCOCCAL INFECTION BY QPCR: DETECTION AND QUANTIFICATION OF DNA/*NEISSERIA MENINGITIDIS* (Abstract): We present the case of a patient with clinical signs of meningococcemia and negative bacterial culture. Microbiological diagnosis was possible only by testing with Real Time PCR technique the cerebrospinal fluid and blood samples. Both pathologic samples were positive for *Neisseria meningitidis* by this rapid and sensitive diagnostic method. **Key words:** MENINGOCOCCEMIA, REAL TIME PCR DIAGNOSIS..

Neisseria meningitidis is an important cause of morbidity and mortality worldwide, causing a spectrum of diseases ranging from asymptomatic porting to meningitis, and even septicaemia (meningococcemia), sometimes with fulminant development (1). Because of the difficulty of early diagnosis and rapid progression, the invasive meningococcal disease (sepsis and /or meningitis) is a potentially fatal disease, which can also cause long-term sequelae (2, 3). Despite the advances in resuscitation and intensive care, case fatality rate remained at 10% in developed countries and can reach 50% in developing countries (4, 5). Of those who survive, 11% have severe complications (6).

CASE REPORT

We present the case of a 22 months old child, male, from a family of average condition from rural area, transferred from The "*St Marie*" Universitary Clinical Children's Hospital, where he was hospitalized for 24 hours with a diagnosis of "febrile syndrome, acute nasopharyngitis, dispeptic syndrome". The onset of the disease was sudden, 12 hours prior to his admission to Children's Hospital with fever (39.9°C), chills, coldness, phenomena which occurred on a background of vomitting, diarrhea and watery rhinorrhea (which evolved about 14 days and were treated symptomatically in ambulatory). In pediatrics there was rapid worsening of the general condition and the petechiaes, rash, exanthema appearing on the chest, with rapid generalization throughout the body, having shock and meningeal contracture syndrome. Biohumoral test revealed 6280 leukocytes /mmc with PMN 72.4%, the decreasing

number of thrombocytes (from 257000/ mmc to 83000/mmc), increased TQ and PTTK clotting time, decreased prothrombin activity and the lumbar puncture reveals 8 elements / mmc. Ceftriaxone was administered (1 g), and then the patient was referred to the Clinic of Infectious Diseases. Family history record: parents apparently healthy, smokers. Personal history of pathology: insignificant for the present disease; the only one to mention is the nasopharyngitis on which the present disease started. The clinical examination performed at admission in our unit showed a bad general condition, weakness, generalised necrotic petechial, rash exhantema (fig. 1), hemodynamic instability (BP 87/64 mmHg, 173/min PP AV, cold limbs) and meningeal contracture syndrome. Prognostic score (determined according to Stiehm-Damroch and Niklasson criteria) was 5 (very severe).

Fig. 1. Petechial rash

The petechial necrotic rash with rapid expansion, accompanied by fever, shock phenomena and the meningeal syndrome suggested a meningococcal infection (purpura fulminans, acute meningococcemia or meningococcal meningitis). Biohumorally leukocytosis with neutrophil polynucleosis (NL 14820/mmc, 81%), thrombocytopenia (Tr 67000/mmc). The prognostic score 24 hours after admission was thus 2, a good prognostic indicator. Blood culture, direct bacteriological culture and latex agglutination (LA) of cerebrospinal fluid (CSF) were negative. A sample of CSF and one of blood collected on admission were sent to the Virology Laboratory of the Microbiology Discipline for RT-PCR analysis.

Real Time PCR Diagnosis: DNA / *Neisseria meningitidis* was purified using the kit *PrimerDesign Precision*^{TM} *Gram Negative Bacterial DNA extraction.* The kit has the advantage of rapidity (a sample of DNA can be purified in 16 minutes) and required the use of *Beckman Coulter* microcentrifuge and of the *Biosan* thermoblock. The purity and concentration of DNA were analysed with *NanoDrop Pearl* and RT PCR amplification used *Mx3005P Stratagene* thermocycler.

The first stage of the RT - PCR analysis, according to the protocol established in the project application was the detection of DNA / *N. meningitidis* through the method *qualitative end point PCR.* This meant the inclusion in the RT-PCR plate of a positive control and of negative controls (between 1 and 3) to find out the contamination that which can lead to false positive results. If the positive control shows significant fluorescence, it certifies the fact that all the negative results of the tested samples are truly negative, and are not just the result of a PCR experiment failed because of primers, samples quality or polymerase. In the case of qualitative *end point PCR method*, the final calls are based on the value of the final fluorescence; the analysis was made within the experiment of *Quantitative Analysis Plate Read,* which allows the software to mark the positive and negative samples with "+" and "-". This software performs the calculation of a *t test* based on the final values of the fluorescence, the final normal-

ized fluorescence and the fluorescence change pre - and post-experiment. The DNA purified from CSF and blood has been detected as positive for *Neisseria meningitidis* and in fig. 2. a), can be observed the amplification plots of the experiment (for positive control, DNA/meningococci from CSF and from blood respectively).

The second stage involved testing the purified DNA from the same patient through the *Quantitative PCR method*, which uses the standard curve.

The *PrimerDesign*™ genesig kit for *N. meningitidis* use the *TaqMan* principle. Preparation of the standard curve was done by performing 10-fold dilution of the positive control (from 2 x 10^6/µl up to 2 copies/µl). The pathogen detection mix contained 10 µl of 2 x *Precision*^{TM} *Mastermix*, 1 µl *N.meningitidis* Primer/Probe mix, 1 µl internal extraction control primer/probe mix and 3 µl RNAse/DNAse free water for a final volume of 15 µl. Five µl of diluted DNA template was added into each well. To confirm extraction of a valid biological template, endogenous actin beta (ACTB) was quantified in parallel through the FAM channel. The amplification protocol included one cycle for enzyme activation for 10 min at 95°C and 50 cycles of 10 sec denaturation at 95°C, 60 sec annealing and extension at 60°C (7). The *N. meningitidis* specific primer and probe mix was detected through the FAM channel and the internal control were detected through the VIC channel (11). The parameters of the standard curve (efficiency, slope, Rsq) were in the accepted limits by the *Stratagene*'s software and the values obtained were: for CSF sample – 6.801 x 10^3 DNA copies / ml, Ct = 28.47 and for blood sample: 3.406 x 10 DNA copies / ml, Ct = 37.26 (fig. 2, b).

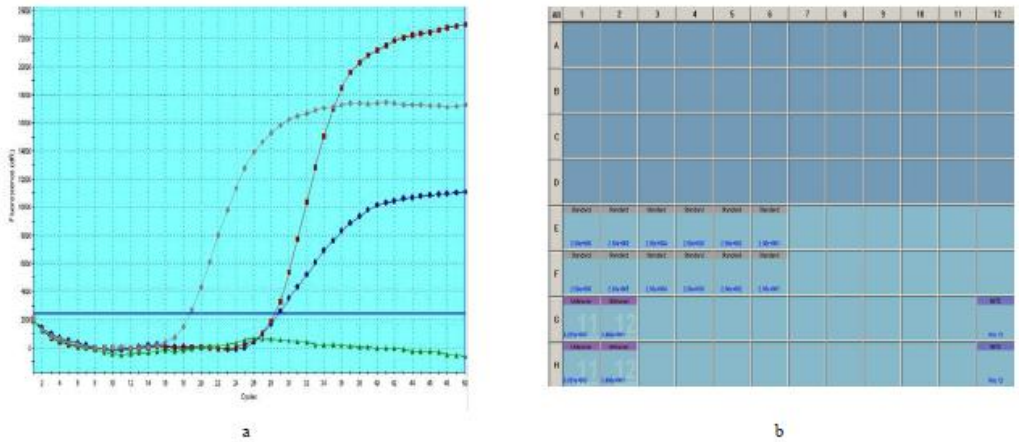

Fig. 2. a) Amplification plots for positive control, CSF and blood sample – end point PCR

b) Initial template quantity of DNA/meningococci in CSF and blood sample – absolute quantification

Under the treatment with Ceftriaxone, 1.5g/day, 10 days, the pathogenetic treatment for shock and cerebral edema, with symptomatic and hygienic-dietary regime, the evolution was favorable, with remission of fever in the 3rd day of hospitalization; he became hemodynamically stable after two days from admission and the meningeal contracture syndrome disappeared after the

7th day. During hospitalization there were no new cutaneous elements. It is still worth mentioning a fever attack (39.2°C) on day 10 of hospital stay without other signs of severity, considered to be of immunological origin, which resolved rapidly under corticotherapy. The final diagnosis, based on the previous clinical data correlated with the laboratory data (RT-PCR of blood and CSF positive for *Neisseria meningitidis*) was that of „Meningococcemia (acute form) with meningitis". The patient was discharged, with improved status after 10 days of treatment, with the persistence of a single petechia (faded) on the trunk.

DISCUSSION

Invasive meningococcal disease (IMD) is a potentially fatal disease which requires prompt treatment and prevention measures to close contacts. In the absence of a rapid diagnostic test for determining causation it is necessary to recognize the typical clinical signs (8). Clinical suspicion of meningococcal infection is based on the presence of hemorrhagic rash associated with symptoms of meningitis / sepsis. Unfortunately, the rash is not present in each case. Therefore, in more than half of the cases presented in the initial stages of the disease the opportunity of an early diagnosis is missed. Also, the initial stages of this infection, signs and symptoms are nonspecific; they are common with the ones specific to simple viral illness, thus making their positive predictive value for IMD to be low. Certain signs, such as cold limbs and pallor may be specific for early diagnosis of sepsis, but their diagnostic value remains to be proven. The number of leukocytes and the C-reactive protein (CRP) are often used by clinicians to differentiate invasive bacterial infection from self-limiting viral diseases, but their diagnostic value in the initial stages of IMD is reduced, none of these investigations being sufficiently sensitive or specific. Procalcitonin (PCT) is an excellent biomarker for invasive bacterial infections. It typically grows in the first 2 h of symptom onset, much earlier than CRP, and can be detected quickly and accurately to bedside (12). PCT was found to be more sensitive and specific than the number of leukocytes and the CRP in the prediction of IMD in children. CSF examination (biochemical data and PMN counting) may be useful for differentiating acute viral meningitis from the bacterial ones. On the other hand, the gold-standard of the microbiological diagnostic remains cultivation from a sterile *situs* such as blood or CSF. Currently, it becomes increasingly difficult to confirm the diagnosis of meningococcal infection by conventional microscopy and culture techniques, because of the early antibiotic treatment, which is recommended by current guides, to improve management and case prognosis (9).

The rate of positive blood cultures ranges from 25-50% and decreases to about 5% when given antibiotics before admission (10, 11). Direct microscopic examination and culture of CSF are positive in 80-90% of untreated cases of meningococcal meningitis, but this rate also decreases in the case of previous administration of antibiotics. In addition, for many patients lumbar puncture it is not possible in the early stages of the disease due to fears of inducing clinical deterioration. Other limitations of conventional diagnostic methods include the time interval until culture positivity and poor sensitivity and specificity of rapid tests such as LA (12).

PCR has the potential to overcome these limitations, through the detection of small

amounts of bacterial DNA in the absence of viable bacteria and under antibiotics treatment. Detection or confirmation of meningococcal infection by DNA amplification was very efficient so that about 50% of meningococcal infections in the UK for which no isolation is available are now confirmed by PCR. The proportion of cases confirmed by non-culture techniques is also increasing in many other countries. Furthermore, PCR can be used to define sero subtypes of meningococci that were previously nontypeable. The screening for the DNA specific to meningococci is carried out currently using the *ctrA s*equence (segment of meningococci capsular biosynthesis locus) specific for clinically significant serogroups (A, B, C, Y, W135, X and 29E) (13).

CONCLUSIONS

RT-PCR is potentially more sensitive than conventional PCR. RT-PCR tests allow rapid and accurate quantification of bacterial load (made of viable and nonviable bacteria). The case shown above proves the fact that the RT-PCR technique is a rapid and sensitive method for the diagnosis of cases of meningococcal infection with classical negative diagnosis following the administration of antibiotics before admission to hospital.

CARACTERISTICILE DESPICĂTURILOR ORO-FACIALE ÎN COLECTIVITĂȚI ÎNCHISE

Georgeta Zegan, Gabriela Lesner
Universitatea de Medicină şi Farmacie "Grigore T. Popa" - Iaşi,
Facultatea de Medicină Dentară,
Disciplina de Ortodonție şi Ortopedie Dento-facială

THE CHARACTERISTICS OF OROFACIAL CLEFTS IN SMALL COMMUNITIES (Abstract): **Aim**: Establishing the prevalence of orofacial clefts in a community of institutionalized children and the correlations with sex, weight at birth, life environment, maternal age and children's associated diseases. **Material and methods**: The study was conducted on a batch of 37 living newly-born (15 boys and 22 girls) from 1987 to 1997, with orofacial clefts, institutionalized in placement centers from Iasi, who survived and were treated medical and surgical. The data were collected from the records found in the archives of these centers and were statistically processed with the EpiInfo 3.4.3. software a Center for Disease Control and Prevention C.D.C. (U.S.A.). **Results**: In 1987, children with orofacial clefts represented 7.42% and in 1997, 2.18% from the total of all children institutionalized. The average rate of prevalence of live births with orofacial clefts was 3.7/year. The frequency of clefts lip and palate in children who survived was 54.06%, clefts lip was 37.84% and clefts palate of 8.10%. Statistically significant correlations were found between the types of orofacial clefts and sex, weight at birth, life environment, maternal age and children's associated diseases ($F_{calculat} > F_{Fisher}$). **Conclusions:** The results confirm the decreased incidence of children with orofacial clefts, the high prevalence of clefts lip and palate the existence of orofacial cleft complications and the need for orthodontic treatment. **Key words:** OROFACIAL CLEFTS, PREVALENCE OF CLEFTS LIP AND PALATE, RISK FACTORS, SURGERY, ORTHODONTIC TREATMENT

Despicăturile oro-faciale sunt tulburări de coalescență a mugurilor faciali, care apar în timpul embriogenezei, fiind prezente la naştere, la nivelul buzei, palatului sau a ambelor, în forme izolate sau în cadrul unor sindroame cromozomiale.

Centrul pentru Prevalența şi Controlul bolilor din S.U.A. (CDC-NBDPN) a consemnat o incidență a despicăturilor de buză cu/fără palat de 10,63 şi de palat de 6,35 per 10.000 nou-născuți vii, 70% reprezentând formele cu despicături izolate (1).

Cauzele acestor malformații nu sunt elucidate, fiind combinația factorilor genetici cu alți factori (mediul, dieta, fumatul şi medicamentele maternale).

Tratamentul este complex, de lungă durată, depinzând de severitate şi de asocierea sindroamelor genetice sau a altor defecte (2). Acesta se impune datorită dificultății de alimentație a sugarului, urmând restabilirea funcționalității şi esteticii maxilofaciale. În primele luni de viață, repararea defectului se face chirurgical, apoi copiii

au nevoie de chirurgie adiţională, dar în special de terapie ortodontică.

Aspectul facial monstruos încă de la naştere produce traume psihice asupra familiilor acestora, iar copiii şi adolescenţii cu despicături au problemele psihice critice (3). Specialiştii din unele ţări consideră despicăturile oro-faciale ca serioase handicapuri, iar după apariţia metodelor precoce de diagnostic fetal (4), au permis avortul.

În acest sens, scopul studiului este de a stabili prevalenţa despicăturilor oro-faciale dintr-o colectivitate de copii instituţionalizaţi, de a determina corelaţiile cu sexul, greutatea la naştere a nou-născuţilor, mediul de proveniență, vârsta maternă şi cu afecţiunile asociate ale copiilor şi de a compara aceste date cu rezultatele studiilor anterioare.

MATERIAL ŞI METODE

Studiul a fost efectuat pe datele din foile de observaţie ale unui lot de 37 de nou-născuţi vii (15 băieţi şi 22 de fete) în perioada 1987 - 1997, cu despicături oro-faciale, proveniţi din Centrele de Plasament din Iaşi ("Sf. Parascheva" nr. 1 şi 2, "Sf. Andrei" şi Bucium). După domiciliul mamelor, nou-născuţii cu despicături oro-faciale proveneau din judeţele Iaşi (n = 16), Botoşani (n = 9), Neamţ (n = 5), Vaslui (n = 3), Bacău (n = 2) şi Slobozia (n = 2), 59% din mediul urban şi 41 % din mediul rural. Copiii au fost diagnosticaţi de la naştere şi au supravieţuit. Lotul de studiu a beneficiat de tratamente chirurgicale la Spitalul "Sf. Maria" din Iaşi, au fost monitorizaţi medical, dar nu şi trataţi ortodontic.

Pentru prelucrarea şi interpretarea statistică s-a utilizat programul *EpiInfo 3.4.3.*, cu analiza variabilelor prin statistică descriptivă, testul Fisher, regresie liniară şi multiplă.

REZULTATE

În 1987, cei 160 copii cu despicături oro-faciale reprezentau 7,42% din totalul copiilor instituţionalizaţi (n = 2150), respectiv 1:13,44 copii, comparativ cu 1997, când cele 25 cazuri reprezentau 2,18% (n = 1146), respectiv 1:45,80 copii (fig. 1). În 1987, cel mai mare procent l-au înregistrat despicăturile de buză 65,30%, cu o distribuţie aproape egală pe sex (50,84% masculin şi 49,16% feminin), iar în 1997, despicăturile de buză au avut o prevalenţă de 42,50% (41,07% masculin şi 58,93% feminin), iar despicăturile de buză şi palat de 57,50% (33,65% masculin şi 66,35% feminin). Distribuţia despicăturilor de palat pe sex a fost de 61,21% la masculin şi de 38,79% la feminin.

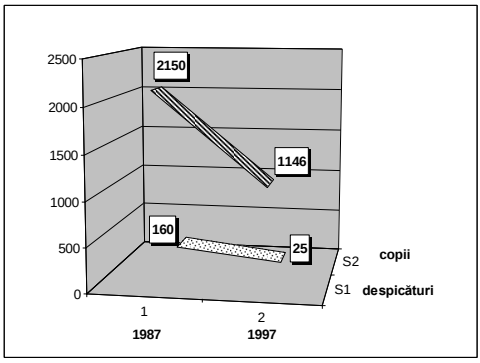

Fig. 1. Dinamica frecvenţei copiilor cu despicături oro-faciale (1987-1997)

Media anuală pentru perioada 1987 - 1997 a nou-născuţilor vii cu malformaţii oro-faciale, a avut o rată de frecvenţă de 3,7/an, respectiv de 1,4/an a despicăturilor de buză, de 2,0/an a despicăturilor de buză şi palat şi de 0,3/an a despicăturilor de palat.

Prevalenţa celor de buză şi palat a fost de 54,06%, a despicăturilor de buză de 37,84% şi a despicăturilor de palat de 8,10%. Despicăturile de buză şi palat sau numai de palat au fost mai frecvente la

sexul feminin, iar despicăturile de buză au fost mai frecvente la sexul masculin. Despicăturile oro-faciale unilaterale au fost mai frecvente de partea stângă (tab. I).

TABELUL I

Distribuția formelor anatomo-clinice ale despicăturilor oro-faciale

Tipul despicăturii	Cazuri		Băieți		Fete	
	n	%	n	%	n	% *
Buză incompletă unilaterală	3	8,11	3	8,11	-	-
Buză incompletă bilaterală	7	18,92	4	10,81	3	8,11
Buză completă unilaterală	4	10,81	1	2,70	3	8,11
Buză şi palat unilaterale	14	37,84	5	13,52	9	24,32
Buză şi palat bilaterale	6	16,22	3	8,11	3	8,11
Palat incompletă	1	2,70	-	-	1	2,70
Palat completă	2	5,40	-	-	2	5,40
Total	37	100,00	16	43,25	21	56,75

* Pentru valorile mai mici de 10, proporțiile sunt orientative

Greutatea la naştere a nou-născuților vii cu despicături oro-faciale a fost normală la 54,06% de cazuri, 18,91% au fost distrofici şi 27,03% au fost supraponderali (tab. II).

Vârsta mamelor care au născut copii vii cu despicături oro-faciale a fost sub 20 de ani în proporție de 5,40%, între 21 şi 34 de ani de 91,89% şi peste 34 de ani de 2,71% (tab. III).

TABELUL II

Formele anatomo-clinice ale despicăturilor oro-faciale în funcție de greutatea la naştere a nou-născuților

Greutate (g)	Despicături de buză		Despicături de buză şi palat		Despicături de palat		Total	
	n	%	n	%	n	%	N	% *
< 2900	2	5,41	4	10,80	1	2,70	7	18,91
3000 – 3900	10	27,03	8	21,62	2	5,41	20	54,06
> 4000	2	5,41	8	21,62	-	-	10	27,03

* Pentru valorile mai mici de 10, proporțiile sunt orientative

TABELUL III

Formele anatomo-clinice ale despicăturilor oro-faciale în funcție de vârsta maternă

Vârsta maternă	Despicături de buză		Despicături de buză şi palat		Despicături de palat		Total	
ani	n	%	n	%	n	%	n	% *
< 20	1	2,70	1	2,70	-	-	2	5,40
21 - 34	12	32,43	18	48,65	4	10,81	34	91,89
> 35	-	-	1	2,71	-	-	1	2,71

* Pentru valorile mai mici de 10, proporțiile sunt orientative

Utilizând testul Fisher ($F_{calculat} > F_{Fisher}$), s-a constatat o pantă de regresie liniară pozitivă pentru corelația semnificativ statistic a formelor anatomo-clinice ale despicăturilor oro-faciale cu vârsta maternă şi pante de regresie liniară negative pentru corelația formelor anatomo-clinice ale despicăturilor oro-faciale cu sexul, greutatea nou-născuților vii şi cu mediul urban/rural al mamelor (tab. IV).

TABELUL IV

Corelațiile formelor anatomo-clinice ale despicăturilor oro-faciale cu variabilele independente

Variabile	r (coeficientul de corelație)	β (panta dreptei de regresie)	F (testul Fisher)
Sex	- 0.31	- 0.8090	3.5902
Greutatea la naştere	- 0.04	- 0.0009	0.0487
Mediul de proveniență	- 0.20	- 0.5363	1.4920
Vârsta maternă	0.22	0.0764	1.8615

Prin regresie multiplă s-au calculat corelațiile formelor anatomo-clinice ale despicăturilor oro-faciale cu afecțiunile asociate ale copiilor care au supraviețuit şi cu unele analize de laborator şi s-au găsit valori semnificativ statistic direct proporționale cu hipodezvoltarea musculară facială, asimetriile faciale, tahicardia, extrasistolelor, timpul de sângerare şi invers proporționale cu tulburările nervilor faciali şi trigemeni şi hipoplazia osoasă facială (tab. V).

TABELUL V

Corelațiile formelor anatomo-clinice ale despicăturilor oro-faciale cu afecțiunile asociate ale copiilor

Variabile	β (panta dreptei de regresie)	F (testul Fisher)
Hipodezvoltare musculară	0.6449	1.04 < F < 1.3999
Asimetrii faciale	0.8601	5.62 < F < 18.3784

DISCUȚII

Un studiu epidemiologic realizat în 34 de state şi 30 de țări între 2002 - 2006 a arătat o creştere în S.U.A. şi o scădere la nivel internațional a prevalenței nou-născuților vii cu despicături de buză cu/fără palat sau a altor malformațiilor congenitale (5).

În lotul studiat, scăderea incidenței copiilor cu despicături oro-faciale, în decursul anilor, este conform datelor de la nivel internațional, dar şi a scăderii numărului de copii instituționalizați în Centrele de Plasament din Iaşi. Dacă în 1987, distribuția

pe sex era aproximativ egală, în 1997, sexul feminin a avut o frecvenţă mare a despicăturilor de buză cu/fără palat, iar cel masculin a despicăturilor de palat.

Studiile epidemiologice estimează că în fiecare an se nasc în S.U.A. 2.651 copii cu despicături de palat şi 4.437 copii cu despicături de buză cu/fără palat (1). Ratele prevalenţei raportate la nou-născuţii vii cu despicături oro-faciale au fost diferite după grupurile rasiale: nativii americani, 3,74/1000; japonezi, 0,82/1000 şi 3,36/1000; chinezi, 1,45/1000 şi 4,04/1000; caucazieni, 1,43/1000 şi 1,86/1000; latinii americani, 1,04/1000; africanii americani, 0,18/1000 şi 1,67/1000. Prevalenţa despicăturilor de luetă a variat între 0,02% şi 18,8%, cea mai mare fiind la indieni şi cea mai mică la africanii americani (6).

În lotul studiat, media anuală a ratei frecvenţei nou-născuţilor vii cu despicături oro-faciale a fost similară cu nativii americani, fiind rata cea mai ridicată din grupurile rasiale a studiilor prezentate.

Despicăturile oro-faciale prezintă variate forme anatomo-clinice, astfel că în 1976, Tessier a descris 16 linii de despicături orofaciale, însă frecvenţa lor de apariţie este mult mai rară (7). În general, sunt definite trei entităţi separate: despicături de buză, despicături de palat şi despicături de buză şi palat. Despicăturile de buză apar mai frecvent de partea stângă sau bilateral. Despicăturile de palat sunt mai frecvente la sexul feminin şi afectează toate rasele umane. Despicăturile de buză şi palat, în care există o comunicare dintre gură şi nas, se numesc şi insuficienţe velo-faringiane şi sunt mai frecvente la sexul masculin, de partea stângă, bilaterale, la asiatici şi la africanii americani.

În studiul nostru, la sexul feminin au fost mai frecvente despicăturile de buză şi palat sau numai de palat, iar la masculin despicăturile de buză. De asemenea, despicăturile unilaterale au fost mai frecvente de partea stângă, aşa cum arată şi datele din literatură.

Cauzele despicăturilor oro-faciale sunt multifactoriale, incluzând factorii genetici, de mediu, chimici/medicamente. Unii autori au menţionat ca factori de risc hipoxia maternală determinată de fumat, alcoolismul şi hipertensiunea maternală.

Prezentul studiu analizează greutatea la naştere a nou-născuţilor vii şi vârsta mamelor la naştere, pentru a găsi o cauzalitate cu despicăturile oro-faciale. Procentul ridicat al cazurilor cu despicături oro-faciale cu greutate normală la naştere a demonstrat că dezvoltarea intrauterină a fătului nu a fost afectată de existenţa unei embriopatii. Numărul mic de copii cu despicături orofaciale aparţinând mamelor cu vârste extreme, nu permite concluzii definitive privind factorii de risc ai despicăturilor. Nu am avut date despre vârsta taţilor şi posibilelor con-sanguinităţii dintre părinţi.

Testul Fisher a arătat o corelaţie semnificativ statistic între despicăturile de palat şi sexul feminin, greutatea mică la naştere a nou-născuţilor şi mediul rural maternal. De asemenea, Testul Fisher a arătat o corelaţie semnificativ statistic între despicăturile de buză şi palat şi greutatea mare la naştere a nou-născuţilor, mediul urban maternal şi vârsta maternă sub 20 ani la naştere.

Complicaţiile care apar la copiii cu despicături oro-faciale sunt multiple. Dezvoltarea maxilo-facială a copiilor este aproape normală în despicăturile oro-faciale necorectate chirurgical, în cele operate apare un deficit de dezvoltare tridimensională, datorită cicatricelor postoperatorii şi a hipoplaziei osoase, cu consecinţe grave asupra funcţiilor complexului dento-maxilar (8).

CONCLUZII

Datele obținute concordă cu cele din literatură, ele demonstrează că despicăturile oro-faciale respectă frecvența populației generale. Valorile mai mari sunt probabil rezultatul structurii populației cercetate din Centrele de Plasament din Iaşi. Realizarea unor astfel de studii oferă date pe termen lung a monitorizării medico-chirurgicale a populației în studiu. Este posibilă extinderea unor studii în alte domenii de interes, pentru unele facilități corecționale.

Mulțumiri

Mulțumim directorului Centrelor de Plasament "Sf. Parascheva" nr. 1 şi 2 pentru ajutorul acordat în realizarea bazei de date aferente acestui studiu.

OVERWEIGHT AND GASTROINTESTINAL SYMPTOMS AMONG ADULTS OF WORKING AGE IN IASI, ROMANIA (Abstract): The objectives were to determine the presence of gastrointestinal symptoms and overweight in a sample of working age adults, from Iasi city (North-East Romania) and relationship with eating habits. **Material and methods:** For this survey a sample was randomly chosen from family doctors records and 158 adults participated (65 males and 93 females, aged 19-64 years). Eating habits and food-frequency questionnaires were conducted, and *Body Mass Index* (BMI), waist and *Body Fat Percent* (FAT) were measured. For recent symptoms we used *Gastrointestinal Symptom Rating Scale* (GSRS). **Results**: 43.1 % of male and 47.3% of female were overweight and 21.5 % of male and 21.6 % of female were obese. The total body fat exceeded its normal limits in 70.8 % of men and in 32.3 % of women. Waist was high (abdominal obesity) in 49.5 % of women and in 26.2 % of men. Present gastrointestinal symptoms were: reflux (23.4%), abdominal pain (8.9%), indigestion (32.9%), diarrhea (6.3%) and constipation (8.9%). Overweight or obese subjects accused reflux, indigestion ($p<0.01$) and constipation ($p<0.05$) more frequently than those with normal weight. *Odd ratio* value and 95 % confidence interval for obese versus normal weighted subjects was 8.23 (2.15-37.58) for reflux and 11.65 (3.34-45.5) for indigestion. **Conclusions**: Our findings up-date epidemiological data and suggest the need to promote healthy eating habits in order to reduce the tendency of obesity and to improve digestive function in population. **Key words**: OVERWEIGHT, GASTROINTESTINAL SYMPTOMS, ADULT AGE.

Many studies in the literature refers to the association between obesity and liver disease, but less has been studied the relationship between nutrition, obesity and gastrointestinal disorders. The objectives of the current work were to determine the presence of gastrointestinal symptoms in a sample of overweight adults of working age, from Iasi City (North-East Region of Romania) and the relationship with eating and life habits.

MATERIAL AND METHODS

For this survey a sample was randomly chosen from family doctors records. The sample size was calculated using population survey or descriptive study random sampling formulas in *EpiInfo 3.5.1*. Final-

ly, 158 adults participated (65 males and 93 females, aged between 20-65 years). A questionnaire about life and eating habits and a food-frequency questionnaire was conducted (1). *Body Mass Index* (BMI), waist and *Body Fat Percent (*FAT) were measured. Obesity was defined by BMI over 30 kg/m^2 and overweight by BMI between 25 and 30 kg/m^2. Waist over 88 cm in women and over 102 cm in men defined abdominal obesity. FAT was measured by bioelectric impedance (OMRON BF306) and classified into low, normal, high and very high categories. Age- and sex- specific body fat cut-offs were used to define excess body fat (2, 3).

For recent symptoms we used Gastrointestinal Symptom Rating Scale (GSRS). The GSRS is a 15-item instrument combined into 5 symptom clusters depicting reflux, abdominal pain, indigestion, diarrhea, and constipation. The GSRS uses a 7-point, Likert-type scale with 1 representing absence of bothersome symptoms and 7 representing very bothersome symptoms. Respondents rated the severity of symptoms over the past week. The reliability and validity of the GSRS are well-documented for use in measuring a range of gastrointestinal symptoms and disorders including gastro-esophageal reflux disease and dyspepsia (4, 5).

For statistical analyses we have used *SPSS 17.0* and *EpiInfo 3.5.1*. Spearman`s rank correlation, cross tabulation chi square test and *odd ratio* revealed relationship between variables (6-8).

RESULTS

Prevalence

Using *BMI criteria*, 28 male (43.1%) and 44 female (47.3%) were overweight and 14 male (21.5%) and 20 female (21.6%) were obese (fig. 1).

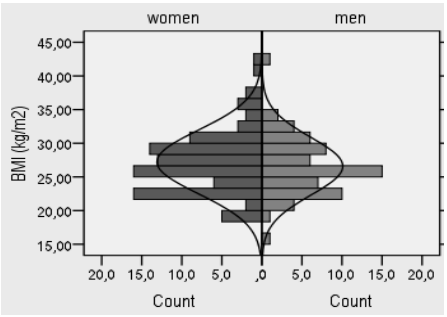

Fig. 1. BMI distribution, by gender

The total body fat was higher in female than male and exceeded its normal limits in 46 men (70.8%) and in 30 women (32.3%), with very high category in 21 men (32.3%) and 8 women (8.6 %) (fig. 2).

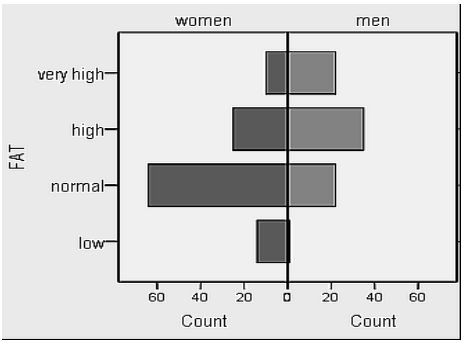

Fig. 2. Body fat categories

Abdominal obesity was present in 46 women (49.5%) and in 17 men (26.2%) (fig. 3).

Fig. 3. Waist categories

Gastrointestinal symptoms were present in the last 7 days preceding the survey: reflux (23.4%), abdominal pain (8.9%), indigestion (32.9%), diarrhea (6.3%) and constipation (8.9%), predominantly in women than men (fig. 4).

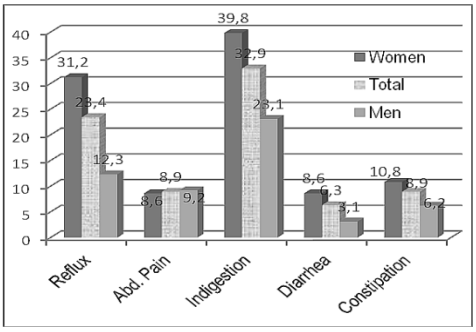

Fig. 4. Gastrointestinal symptoms (%)

Using of Spearman`s rank correlation coefficient and chi square test revealed multiple relationship between variables. All gastrointestinal symptoms were more frequent in the obese than in normal weighted subjects (2 to 5.7 times). Overweight or obese subjects accused indigestion ($p<0.001$), reflux ($p=0.001$), and constipation ($p=0.026$) more frequently than those with normal weight (table I).

Odd ratio value and 95 % confidence interval for obese versus normal weighted subjects was 11.65 (3.34-45.5) for indigestion and 8.23 (2.15-37.58) for reflux.

In our cross-sectional study, using Spearman's rank correlation test, we found statistically significant correlation between frequency of consumption of different food and gastrointestinal symptoms or nutritional status (tables II and III).

TABLE I

Gastrointestinal symptoms and nutritional status cross-tabulation (percent within BMI categories)

			BMI categories			*Total*	*p value ($\chi 2$ test)*

We have found a significant inversely correlation between dairy products, animal fats, vegetables, cereals, fast food and constipation or diarrhea. Reflux was positively related with consumption of herb tea or pulses (table II).

All nutritional status indicators were inversely correlated with consumption of cereals or confectionary. BMI and waist were inversely correlated with meat, animal fats, vegetables and fast-food. FAT percentage was inversely related with dairy products and fish (table III).

DISCUSSION

Our results were compared with national and international studies and we found higher prevalence of overweight / obesity. WHO reported for Romania (2000): overweight 33.1% (28.6% females and 38.1% males) and obesity 8.6% (9.5% females and 7.7 % males) (9). In 2003, a study conducted in our area (Iasi county) revealed 28.7% obesity and 57.8% abdominal obesity, emphasizing with age (between 42.8 and 73%) (10).

An increased prevalence of upper and lower gastrointestinal symptoms was associated with obesity /overweight, as it emerged from previous studies published (11, 12).

The cross-sectional study cannot establish causality, only the relationship between the studied elements. A correlation can have several possible explanations:

1. Frequent consumption of a particular food may positively or negatively influence the presence of disease (for example, pulses are positively correlated with gastro-esophageal reflux, vegetable are inversely related with overweight or constipation);

2. A disease can lead to a certain life-style, sometime in compliance with dietary recommendations (frequently use of herb teas, rarely consumption of animal fat, confectionary and fast-food in obesity);

3. Both factors (disease and diet) may be dependent on a third factor - for example socio-economical status.

CONCLUSIONS

Our findings update epidemiological data and suggest the need for strategies and coordinated efforts at all levels to promote healthy eating habits to reduce obesity and high body fat and to improve digestive function in population.

ACKNOWLEDGEMENTS

We are extremely grateful to the family care physicians from Pacurari Medical Center, esp. Dr. Anca Deleanu and Dr. G. B. Murariu, who helped us to contact and to question their patients. We also thank Mr. L. V. Boiculese for guidance in application of statistical tests.

The research was partially supported by the project POSDRU/88/ 1.5/S/63117.

MORPHOPATHOLOGICAL CHANGES IN GLAUCOMA-INDUCED TRABECULAR MESHWORK (Abstract): Glaucoma causes trabecular meshwork and Schlemm canal changes, resulting in the obstruction of the aqueous flow at this level. **Aim**: To show the histological changes in the surgically removed trabecular meshwork tissues. **Material and method**: Trabecular meshwork fragments were histologically processed for histological diagnosis. **Results**: 29.87% of all patients had ordered structure with high eosinophilia, 20.12% a rare structure with high eosinophilia, 21.34% a voluminous trabecular meshwork with fusiform cells, 21.03% tissue fibrosis and 7.62% had tissue necrosis. **Conclusions**: Aqueous flow obstruction in trabecular meshwork is produced by the histological changes at this level, found in all tissue specimens removed during surgery. **Key words**: GLAUCOMA, TRABECULAR MESHWORK, PATHOLOGY, IRIS STROMA

Glaucomul cu unghi deschis (GUD) este o formă tipică caracterizată prin următorii parametri: presiune intraoculară (PIO) mai mare de 21 mm Hg la cel puţin un ochi; un unghi deschis al camerei anterioare, de aspect normal, cu nici o modificare aparentă oculară sau sistemică, care ar putea determina o presiune intraoculară crescută; câmp vizual tipic, de tip glaucomatos şi/sau afectarea capului nervului optic.

Conjunctiva, corneea şi sclera în general au aspect normal. Uneori, în stadiu mai avansat, se constată dilatarea vaselor episclerale. Pe faţa endotelială a corneei pot fi găsite granule pigmentare iar în stadiu mai avansat, irisul prezintă zone întinse de atrofie care se manifestă printr-o rarefiere difuză a stromei anterioare şi a stratului pigmentar cu atrofia coleretului pigmentar, irisul prezintă în unele locuri orificii, iar la nivelul corpului ciliar, musculatura este înlocuită cu ţesut fibros (2,5).

Reţeaua trabeculară în glaucomul cu unghi deschis (GUD) nu are o afectare singulară. Creşte numărul de teci care înconjoară fibrele elastice, uneori umplând regiunea cribriformă. Studii cantitative au arătat întecuirea fibrelor elastice din regiunea cribriformă la 12% din ochii normali şi aproximativ 22% din ochii cu glaucom (1). O altă afectare a reţelei trabeculare în GUD este îngroşarea traveelor corneosclerale şi uveale. Unirea traveelor trabeculare se poate întâmpla în spaţiile unde membrana bazală este expusă umorii apoase, obliterând spaţiile apoase la acest nivel. O altă ipoteză poate fi acumularea de material amorf

care întăreşte reţeaua trabeculară şi nu ii permite expansiunea şi mişcarea indusă de contracţia muşchiului ciliar (2). Aceste întecuiri pot fi groase în ochi cu PIO maximală de 26 mm Hg sau pot fi normale la ochi cu presiune maximală de 36 mm Hg. Îngroşarea reţelei trabeculare acompaniază glaucomul dar nu este cauza singulară a creşterii PIO (2). Materialul care îngroaşă traveele trabeculare se găseşte şi la nivelul peretelui extern al canalului Schlemm şi în spaţiile interstiţiale dintre prelungirile anterioare ale fibrelor muşchiului ciliar (1).

Studiu histologic urmăreşte să evidenţieze modificările primare de cele secundare care pot fi cauzate de terapia medicamentoasă, modificări reactive din timpul intervenţiilor chirurgicale sau fibroză reactivă. Este posibil ca îngroşarea traveelor trabeculare să nu fie urmare a tratamentului medicamentos sau a fibrozei reactive (5).

Lucrarea urmăreşte să evidenţieze modificările morfopatologice, pe preparatele pentru biopsie trabeculare obţinute prin trabeculectomie.

MATERIAL ŞI METODĂ

Am efectuat un studiu retrospectiv pe 328 de pacienţi cu glaucom internaţi în Clinica II Oftalmologie Iaşi, în perioada 1 ianuarie 2001-31 decembrie 2010, care au fost supuşi trabeculectomiei ca urmare a unor glaucoame decompensate tensional (PIO peste 21,5 mm Hg sub triplă asociere). Biopsiile rezultate au fost examinate în serviciul de anatomie patologică din spitalul Prof. „N. Oblu" Iaşi iar rezultatele au fost interpretate în relaţie cu gradul de afectare glaucomatoasă şi cu durata în care a acţionat o PIO crescută. Prelucrarea datelor a fost realizată prin sisteme MS Excel 2007 şi *SPSS 16.0*.

REZULTATE

Lotul a fost format din 328 de pacienţi dintre care 166 (50,60%) bărbaţi, iar pe grupurile de vârstă 60-79 (28,4% feminin şi 24,6, masculin) (tab. I).

TABELUL I.

Repartizarea pacienţilor după grupe de vârstă şi sex

Grupuri de vârstă (ani)	Feminin		Masculin		Total cazuri	
	Nr.	%	Nr.	%	Nr.	%
0-9	18	6,89	27	10,37	45	17,26
10-19	1	0,38	5	1,91	6	2,29
20-29	1	0,38	1	0,38	2	0,76
30-39	9	3,44	6	2,29	15	5,73
40-49	5	1,91	12	4,59	17	6,50
50-59	21	8,04	28	10,72	49	18,76
60-69	42	16,09	45	17,24	87	33,33
70-79	51	19,54	36	13,79	87	33,33
80-89	12	4,59	6	2,29	18	6,88
90-100	2	0,76	0	0	2	0,76
Total	162	-	166	-	328	100,00

Pacienţii au fost examinaţi clinic, oftalmologic: acuitatea vizuală; gonioscopia; ex. FO şi a CV.

Pacienţii care prezentau PIO peste 21,5 mm Hg sub triplă asociere sau la care aceasta era normală (sub 21,5 mm Hg) dar cu modificări ale nervului optic (creşterea excavaţiei papilare) sau cu o evoluţie nefavorabilă a câmpului vizual, au fost supuşi trabeculectomiei.

Fragmentele de trabecul excizate au fost fixate în formol 15%, incluse în parafină, realizându-se secţiuni longitudinale de 50 şi grosimea de 4 microni. Secţiunile au fost colorate cu hematoxilin-eozină şi examinare de microscopul optic. (fig. 1, 2, 3, 4, 5).

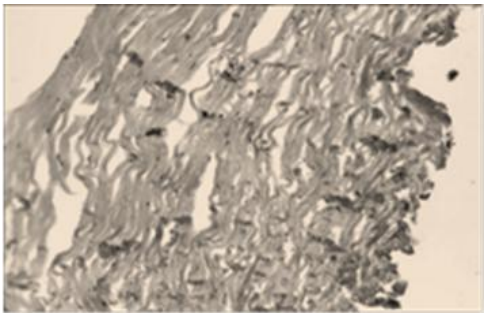

Fig. 1. Fragment de sclerotică.
Se observă structura ordonată a straturilor de ţesut conjunctiv dens.

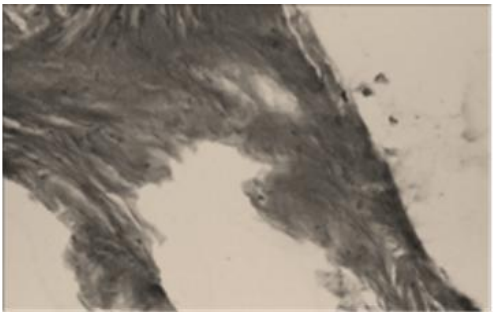

Fig. 2. Fragment mic trabecular slab celularizat.
Se observă o densitate rară a celulelor.

Fig. 3. Se observă numeroase celulele fuziforme, cu citoplasmă eozinofilă şi nuclei alungiţi situaţi în centrul celulei

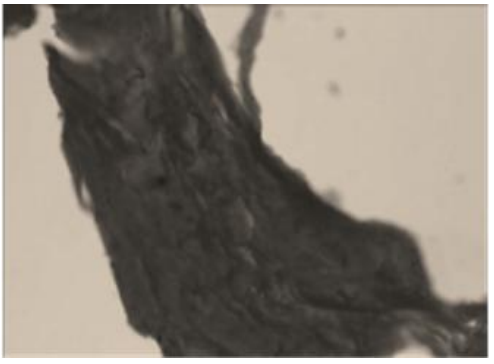

Fig. 4. Aspect de sclerozare a ţesutului conjunctiv prin bogăţia de colagen.

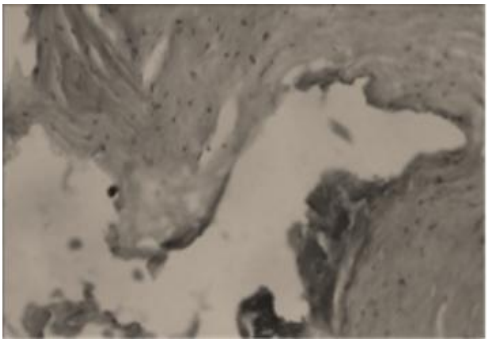

Fig. 5. Lamele trabeculare si spatii intertrabeculare cu modificări minime.
Se evidenţiază o zona necrozată întinsă pe una din margini.

TABELUL II.

Modificările histopatologice evidenţiate pe fragmentele de trabecul excizate chirurgical

Modificări histopatologice	Nr.	%
Structură ordonată a trabeculului cu eozinofilie	98	29,87
Structură celulară rară cu eozinofilie	66	20,12
Trabecul voluminos cu structură celulară densă, celule fuziforme	70	21,34
Fibroză tisulară	69	21,03
Necroză tisulară	25	7,62

Modificările histologice determinate în apariţia glaucomului au fost evidenţiate la nivelul unghiului camerular (tab. II). Constatările histomorfologice ale unghiului formează baza teoriilor referitoare la etiopatogenia bolii. Aplazia sau hipoplazia canalului Schlemm, se observă destul de rar şi apare ca fenomen secundar. În unghiul camerular se descrie persistenţa unei membrane mezodermale care acoperă sistemul trabecular.

Cercetările noastre au evidenţiat abundenţa colagenului cu sclerozarea trabeculului, creşterea importantă a celularităţii urmată de îngroşarea lamelor şi pensarea spaţiilor, aspecte de necroză pe întinderi variate, pe una din feţele trabeculului.

DISCUŢII

Preparatele rezultate prin trabeculectomie de la pacienţi care nu beneficiază de tratament înaintea intervenţiei chirurgicale au fost similare: îngroşarea traveelor şi a lamelelor cu prezenţa abundentă a colagenului(3). Alt studiu (2) a arătat că ochii cu GUD enucleaţi la autopsie sunt cu un grad de afectare glaucomatoasă mai redus decât cei care sunt supuşi intervenţiei chirurgicale. Comparaţia ochilor trataţi cu diverse medicaţii topice (beta blocanţi, pilocarpină sau analogi prostaglandinici) nu a arătat diferenţe histologice(5). Dacă există o supresie cronică a fluxului apos care determină modificări secundare ale reţelei trabeculare (compactarea debriurilor şi a materialului extracelular la acest nivel), acestea devin aparente în regiunea cribriformă şi compactarea lamelelor în regiunea corneoscleralã.

Rohen et al. (3) a observat că celulele trabeculare sunt în număr scăzut la ochii cu GUD dar fără a fi posibilă menţionarea stării anterioare în ce priveşte densitatea celulelor trabeculare la naştere. Gottanka et al. (2) consideră că un proces patologic determină creşterea pierderii celulelor trabeculare în glaucom, descoperirea şi stoparea sa ar favoriza eficienţa tratamentului. În contrast, dacă ochii cu GUD au mai puţine celule trabeculare, pierderea legată de vârstă poate cauza glaucomul printr-o simplă lipsă a celulelor trabeculare pentru a menţine un flux apos fiziologic.

Lutgen-Drecoll et al. (1) menţionează rezultatele unui studiu realizat pe ochii enucleaţi la necropsie şi pe preparatele obţinute prin trabeculectomie, când a evidenţiat modificări celulare şi artefacte ca urmare a manevrelor impuse de examinarea histologică.

În studiile noastre anatomopatologice am observat prezenţa de colagen abundent cu sclerozarea trabeculului (70 preparate), creşterea importantă a celularităţii şi îngroşarea lamelor cu pensarea spaţiilor intertrabeculare (98 preparate), aspecte de ne-

croză pe arii mai mici sau extinse pe una din feţele trabeculului (25 preparate).

CONCLUZII

Rezultatele studiului nostru sunt în concordanţă cu cele ale altor autori, evidenţiază blocarea dinamicii umorii apoase la nivel trabecular, datorită modificărilor histologice care determină creşterea PIO cu modificări consecutive la nivelul papilei nervului optic, urmate de scăderea parametrilor funcţionali. Stoparea sau anularea acestor modificări histologice ar putea fi realizată printr-o terapie farmacologică care să determine ameliorarea evoluţiei fără intervenţie chirurgicală.

NOUTĂȚI

SIRT3: ŢINTIND DIRECT PROCESUL DE ÎMBĂTRÂNIRE

O enzimă, vsirtuina sau Sirt3, reprezentând o diacetilază mitocondrială, ar putea revoluţiona, prin combaterea extrem de activă a oxidărilor celulare, întârzierea îmbătrânirii. Studii efectuate pe animale de laborator au arătat faptul că restricţionarea aportului caloric are ca efect direct o creştere substanţială a concentraţiei Sirt3 în organism. Sirt3 elaborată în exces va interveni prin reducerea nenumăratelor specii reactive de oxigen (produse în mitocondrii în cadrul reacţiilor declanşate de stresul oxidativ), care stau la baza îmbătrânirii. La rozătoare,scăderea aportului caloric determină scăderea potenţialului de membrană la nivel mitocondrial, cu prăbuşirea ratei de producere a radicalior liberi şi neutralizarea acţiunii lor de către Sirt3. Stoparea de către Sirt3 a proceselor complexe de degradare celulară ar putea duce la o încetinire considerabilă a îmbătrânirii. (Liu Y.,Zhang D.,Chen D.SIRT3: Stricking at the heart of aging. *Aging* 2011;3(1):1-3).

SURFACE CHARACTERISTICS OF THE ACRYLIC RESINS ACCORDING TO THE POLISHING METODS (Abstract): **Aim:** The objective of this study was to evaluate the effect of the polishing technique and glazing on the porosity of the dental resins. **Material and methods:** The studied resins were: Castapress/Vertex, Prothyl Hot/Zermack, Rapid Simplified/Vertex, Duracryl Plus/Spofa Dental, Vertex-Soft/Vertex, Superacryl Plus/Spofa Dental. Thirty specimens, five for every resin, of 50/25/2 cm in size were done. One surface of each sample was polished with extrahard tungsten carbide burs, the other surface being polished with extrahard extrafine and diamond burs. The final polishing was done using a conventional method: pumice, water and lathe bristle brush for 90 seconds, 1500 rpm and soft leather polishing wheel for 90 seconds, 3000 rpm. Twenty surfaces were glazed after polishing with Glaze™/Bosworth. Vertex Soft specimens were not polished because this is a resilient material. Surface porosity of the acrylic resin specimens was measured by optical microscopy. **Results:** The lowest porosity was obtained by conventional polishing combined with glazing techniques. No differences between glazed and non/glazed self-curing resin specimens were noticed, but there were differences between self-curing and heat-curing resins. **Conclusions:** Conventional lathe polishing method is an effective and reliable technique for polishing dental resins. Specimens of self-curing resin had a higher porosity than heat curing resin following the same surface treatment. Higher surface smoothness was obtained by conventional lathe polishing completed by glazing. **Key words**: ACRYLIC RESINS, POROSITY, POLISHING, GLAZING

Protezele dentare trebuie să prezinte suprafețe externe netede, perfect lustruite pentru a preveni colonizarea microorganismelor, acumularea plăcii bacteriene, modificările cromatice şi structurale, menținând astfel confortul şi sănătatea țesuturilor orale (1).

Porozitatea răşinilor este un fenomen complex cu origine multifactorială (2). Deşi numeroase studii au avut ca obiectiv evaluarea calitativă şi/sau cantitativă a porozității răşinilor acrilice, încă nu a fost impusă o standardizare unanim acceptată a dimensiunilor porilor. Conform Asociației Dentare Americane (ADA) "nu trebuie să existe bule sau goluri când sunt vizualizate fără magnificație", subliniind faptul că evidențierea clinică este dificil de realizat. Literatura de specialitate incriminează porozitățile

rășinilor acrilice ca factor favorizant al stomatopatiilor paraprotetice şi al fracturilor bazelor protezelor, obiectivată de prezența acestora pe linia de fractură şi la nivelul interfeței dinte artificial/baza protezei. Referitor la porozitatea rășinilor acrilice, rezultatele studiilor experimentale au fost extrem de variabile, dimensiunile încadrându-se între 10 şi 300 μm (3) fiind raportate însă şi valori mult mai mari - 500μm (4). Clasificarea acceptată şi utilizată în prezent îi diferențiază în pori mici (circa 10 μm diametru), pori medii (10-30 μm diametru) şi pori mari (peste 30 μm diametru).

Scopul studiului a constat în analiza prin microscopie optică a morfologiei suprafețelor (prezența impresiunilor mecanice rezultate în urma şlefuirii), a porozităților şi a incluziunilor, urmărind dimensiunea şi repartiția acestora, precum şi starea de suprafață după procesul de glazurare, a şase rășini acrilice cu regim de polimerizare diferit (autobaropolimerizare şi termopolimerizare) care au fost supuse la prelucrări mecanice diferite.

MATERIAL ŞI METODĂ

Rășinile studiate au fost alese dintre cele mai frecvent utilizate în protetica dentară: Castapress/Vertex, Prothyl Hot/Zermack, Rapid Simplified/Vertex, Duracryl Plus/ Spofa Dental, Vertex - Soft/Vertex, Superacryl Plus/Spofa Dental. S-au realizat treizeci de probe, împărțite în şase grupe (A-F) formate din cinci plăcuțe pentru fiecare tip de rășină.

Probele au fost realizate sub formă de plăcuțe paralelipipedice cu lungimea de 50 mm, lățimea 25 mm şi grosimea 2 mm. Machetele plăcuțelor au fost transformate în probe finale respectând algoritmul tehnologic specific fiecărei clase de rășină acrilică: termopolimerizare (B, C, D, F) şi autobaropolimerizare (A, E).

Prelucrarea şi lustruirea probelor s-a făcut în mod diferit pe fiecare suprafață a plăcuțelor, viteza şi timpul de prelucrare fiind identice (30 secunde, 1500 rpm). Suprafețele au fost notate cu literele A-F, respectiv A'-F'.

Prelucrarea mecanică s-a făcut cu o freză extradură din carbură de tungsten cu granulație fină (galbenă) pentru suprafețele: A, B, C, D, E, F iar pentru suprafețele A', B', C', D', E', prelucrarea s-a făcut atât cu o freză extradură cu granulație extrafină de 53-63 μ de formă conică cât şi cu o freză diamantată cu granulație fină (roşie) de formă cilindrică, cu vârful rotunjit.

Lustruirea finală a avut ca obiectiv obținerea unui "luciu de oglindă" şi s-a realizat cu praf abraziv pentru lustruit (Polishing powder/Astar Fedent) şi pastă abrazivă (High lustre polishing paste) acționate de perii şi filțuri.

Proba F', fiind dintr-un material rezilient, care se utilizează doar pe suprafața mucozală a protezei, a beneficiat de o prelucrare uşoară cu praf Vertex™ Soft. Lustruirea a fost făcută cu praf abraziv (Astar-Fedent) şi pastă abrazivă, încărcate pe un con din pâslă (filț) şi puf de bumbac (tab. I).

Glazurarea a fost realizată în cazul probelor: C, C', D' şi E, cu agentul de glazurare Bell Coat/K B Mutsumi (glazură fotopolimerizabilă pentru rășini acrilice şi materiale compozite). Acesta a fost aplicat prin pensulare în strat subțire, după ce suprafața a fost în prealabil uscată foarte bine, şi apoi fotopolimerizat timp de patru minute

Examinarea probelor s-a realizat prin microscopie optică în scopul analizării morfologiei suprafețelor, porozităților şi incluziunilor, urmărind dimensiunea şi repartiția acestora, precum şi starea de suprafață după procesul de glazurare. Am utilizat microscopul optic cu lumină fluorescentă şi polarizată Leica SM 2500 M, cu magnificație

x20 şi x50. Stocarea şi prelucrarea datelor a fost realizată cu ajutorul programului Apllication Leica. Inițial s-a realizat o inspecție de ansamblu a întregii suprafețe a probelor pentru aprecierea omogenității stării de suprafață. Deoarece starea de suprafață la magnificație x20 a fost omogenă pe toată aria, analiza detaliilor a fost realizată la o magnificație x50, pe trei câmpuri alese aleator.

TABELUL I
Regimul de polimerizare pentru fiecare probă

Proba	Denumirea comercială	Regimul de polimerizare
A, A’	Castapress/Vertex	30 minute la 55º C şi 2.5 bar
B, B’ C (glazurat) C’(glazurat)	Prothyl hot/Zermack	5 minute de la 80° la 100°C + 20 minute la 100°C
D D’(glazurat)	Rapid Simplified/Vertex	20 minute la 100°C
E (glazurat) E’	Duracryl Plus/Spofa Dental	30 - 40°C / 0,2 - 0,3 MPa.
F’	Vertex- Soft/ Vertex	3 ore la 70º C, urmat de 30 de minute la 100º C
F	Superacryl Plus/Spofa Dental	Temperatura creşte în 30 minute până la 70ºC, 30 minute se menține la 70ºC, urcă în 30 minute până la 100ºC, 30 minute ramâne la 100ºC.

REZULTATE ŞI DISCUȚII

În cazul răşinii Castapress/Vertex, suprafețele A au prezentat numeroşi pori de dimensiuni de până la 2 µm, repartizați uniform, şi incluziuni de dimensiuni mari (până la 24,5 µm) cu repartiție neuniformă în câmpurile analizate (fig.1). S-a constatat faptul că incluziunile de dimensiuni mari au o formă neregulată spre deosebire de porozitățile caracterizate de forma sferică. Suprafețele A’ s-au caracterizat, în general, prin absența incluziunilor de dimensiuni mari şi o prezență redusă a porilor, cu păstrarea liniilor de prelucrare mecanică.

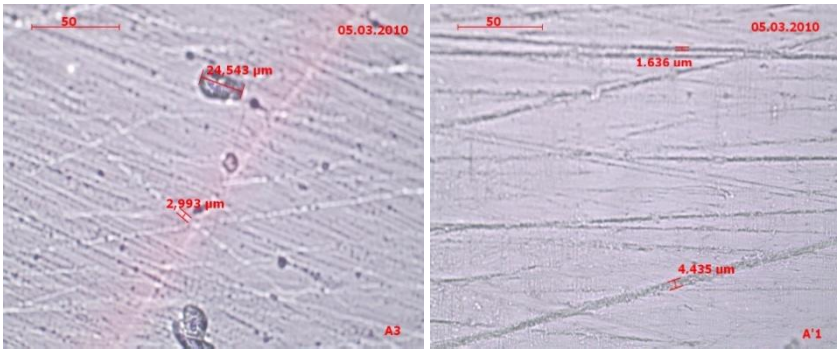

Fig. 1. Aspecte microscopice ale suprafețelor răşinii Castapress/Vertex X50

În cazul răşinii Prothyl Hot/Zermack, suprafețele B şi B’ rezultate consecutiv celor două tipuri de prelucrare, s-au caracterizat printr-o prezență redusă a porilor pe suprafață. În cazul suprafețelor B s-au evidențiat mai multe impresiuni mecanice (fig. 2).

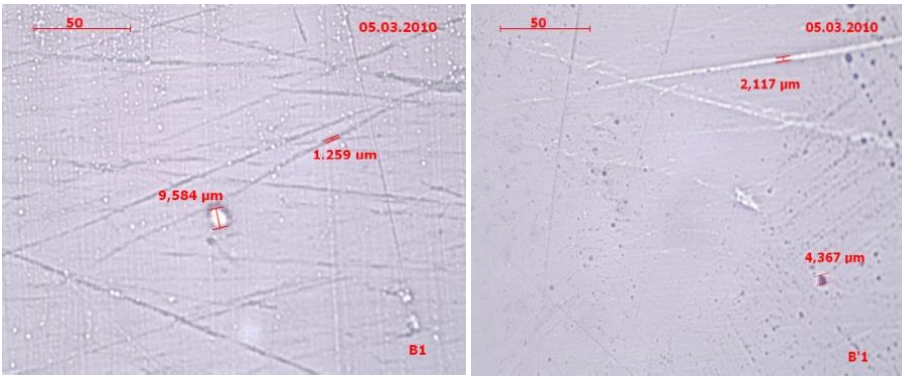

Fig. 2. Aspecte microscopice ale suprafețelor rășinii Prothyl Hot/Zermack X50

În cazul probelor din rășina Prothyl Hot/Zermack, la care ambele suprafețe au fost glazurate cu Bell Coat, s-a observat că după prelucrarea cu freza de carbură de tungsten pelicula de glazură acoperă impresiunile mecanice produse de instrumentarul abraziv, prezentând în acelaşi timp ea însăşi pori de dimensiuni foarte mici, de aproximativ 2 µm (fig. 3). Suprafața C', prelucrată cu freze extrafine şi freze diamantate a prezentat doar porii de mici dimensiuni (circa 3 µm) ai peliculei de glazură.

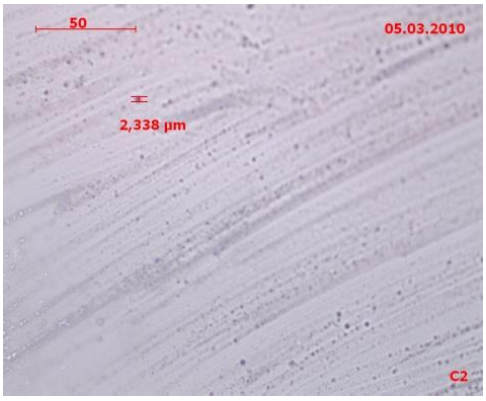

Fig. 3. Aspecte microscopice ale suprafețelor C ale rășinii Prothyl Hot/ Zermack (glazurată) X50

Aceleaşi aspecte s-au regăsit şi în cazul probelor realizate din rășina Rapid Simplified/ Vertex (fig.4).

În cazul rășinii Duracryl/Spofa Dental analiza microscopică a suprafețelor glazurate cu Bell Coat a evidențiat faptul că incluziunile de mari dimensiuni nu au putut fi acoperite de agentul de glazurare. In cazul imaginilor suprafețelor E' (neglazurate) s-a constatat prezența porilor cu dimensiuni de aproximativ 6,5 µm şi prezența impresiunilor de şlefuire (fig.5).

Imaginile captate în cazul rășinii Superacryl Plus/Spofa Dental au evidențiat suprafețe regulate, cu puțini pori, de mici dimensiuni şi absența impresiunilor consecutive prelucrării mecanice. Suprafețele F' căptuşite cu materialul rezilient Vertex Soft, au prezentat o textură spongioasă din cauza încorporării de incluziuni de aer în material (fig.6).

În studiul nostru, repartiția incluziunilor nu a fost uniformă la toate tipurile de rășini luate în studiu, rășinile autobaropolimerizabile prezentând astfel de incluziuni şi o porozitate mai mare, rezultatele fiind concordante cu cele ale altor studii (5). Incluziunile pot fi de diferite forme şi dimensiuni, repartizate în toată grosimea acrilatului, având drept cauze: repartiția defectuoasă a monomerului, variația prea mare a masei moleculare a polimerului sau lipsa omogenizării pastei de acrilat (6).

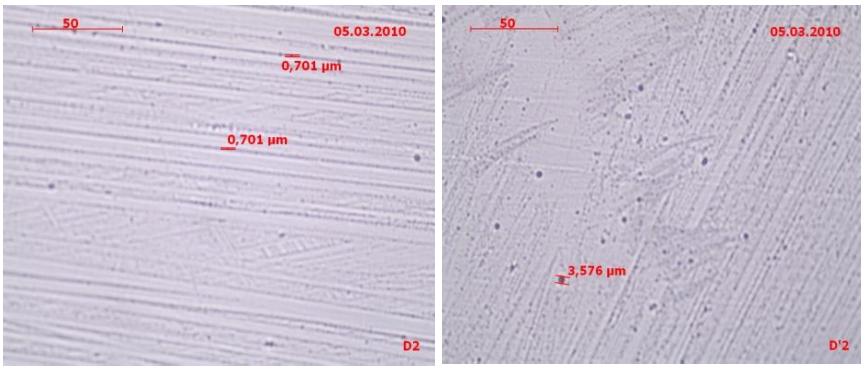

Fig. 4. Aspecte microscopice ale suprafețelor rășinii
Rapid Simplified/ Vertex X 50 (D- neglazurată, D - glazurată)

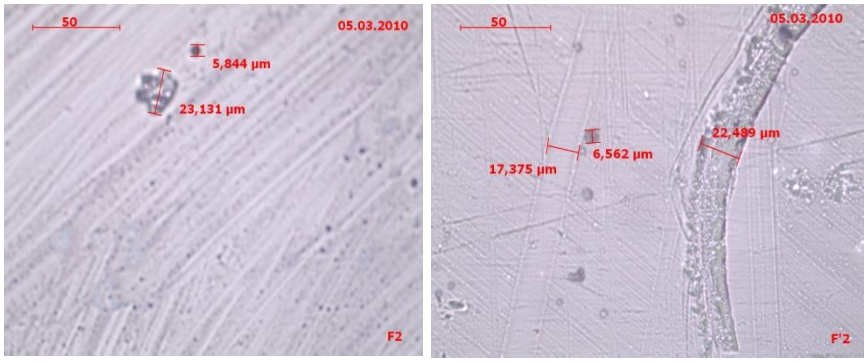

Fig. 5. Aspecte microscopice ale suprafețelor rășinii
Duracryl Plus/Spofa Dental- E glazurată, E' neglazurată X50

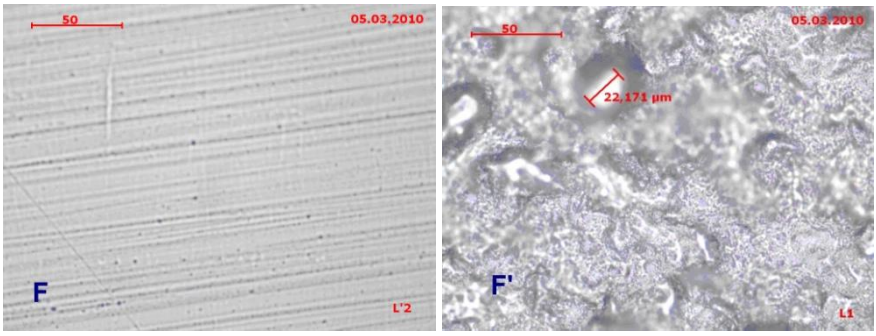

Fig. 6. Aspecte microscopice ale suprafețelor rășinii Superacryl Plus (F) și a rășinii Vertex Soft (F') x50

Indiferent de porozitatea materialului, s-a observat că prelucrarea și lustruirea până la "luciu de oglindă" determină o reducere a dimensiunii și numărului porilor de suprafață, valorile obținute fiind de până la 10 µm diametru. La examinarea prin microscopie optică s-a observat că prin prelucrarea cu ambele tipuri de freză - extradură și diaman-

tată -, porozitatea a fost mai mică decât în cazul prelucrării doar cu freza extradură. In acelaşi timp, prelucrarea numai cu freza extradură induce existența unor impresiuni mecanice mult mai evidente. Analizând aceste două aspecte calitative ale stării de suprafață, apreciem că prelucrarea cu freză extradură şi freză diamantată induce o suprafață cu calități mult mai bune comparativ cu prelucrarea doar cu freză extradură.

Referitor la glazurare, pe baza imaginilor obținute prin microscopie optică putem afirma că starea de suprafață după procesul de lăcuire prezintă calități superioare suprafețelor nelăcuite sub aspectul porozității şi impresiunilor mecanice postprelucrare.

CONCLUZII

S-a observat că indiferent de porozitatea materialului, prelucrarea şi lustruirea determină o reducere a dimensiunii şi numărului porilor de suprafață.

Prelucrarea realizată atât cu freza extradură cât şi cu freza diamantată, conduce la reducerea numărului de impresiuni mecanice.

În studiul nostru, repartiția incluziunilor a fost diferită pentru rășinile luate în studiu, cele autobaropolimerizabile prezentând incluziuni şi porozități mai numeroase. Prezența incluziunilor poate influența negativ rezultatul prelucrării mecanice a suprafeței, ele apărând evidente în timpul contactului dintre instrumentarul rotativ şi rășină, determinând creşterea rugozității materialului.

Utilizarea procedurii de glazurare permite optimizarea parametrilor de suprafață.

CONTRIBUŢII LA ALEGEREA FAZEI MOBILE ÎN VEDEREA SEPARĂRII PRIN HPLC ŞI IDENTIFICAREA – DETERMINAREA CANTITATIVĂ A UNOR ANTIINFLAMATOARE NESTEROIDIENE FOLOSIND DETECTORUL UV-VIS

J. Negru[1], A.F. Şpac[2], V. Dorneanu[1]
Universitatea de Medicină şi Farmacie "Gr.T. Popa" Iaşi

2. Disciplina Chimie Fizică

CONTRIBUTION TO THE MOBILE PHASE SELECTION FOR HPLC SEPARATION IN ORDE TO MAKE THE IDENTIFICATION AND QUANTITATIVE DETERMNATION USING THE UV-VIS DETECTOR (Abstract): The aim of this study is to elaborate a HPLC with UV detection method for the analysis of some AINS, method which can be transferred in a system with mass spectrometry detection. **Material and methods**: More AINS drugs (diclofenac sodium, ibuprophen, ketoprofen, meloxicame, piroxicame, tenoxicame, nimesulide, phenylbutazone and indomethacin) were studied by UV spectrophotometry and by HPLC. **Results**: The UV spectra of the studied AINS were recorded in pure solvents or in a mixture of solvents in order to establish the absorbance that will be used for HPLC detection in UV. To establish the optimum chromatographic parameters, the influence of the flow and of the composition of the mobile phase (both of the aqueous and organic phases) were studied too. **Conclusions**: The proposed procedure is easy and relatively with low cost regarding the MS detection. **Key words**: AINS, HPLC, SPECTROPHOTOMETRY.

Pentru medicamentele antiinflamatoare nesteroidiene (AINS), care sunt de importanţă majoră în terapeutică, în literatura de specialitate studiată nu există o singură metodă analitică pentru separarea şi determinarea cantitativă a fiecărui component din amestec, ci numai metode pentru fiecare compus în parte sau pentru un număr restrâns dintre AINS (1-7). O asemenea metodă poate fi aplicată pentru analiza AINS din probe biologice, determinând componentul administrat dintr-o gamă mai largă de AINS. Ne-am propus realizarea unei metode de separare prin HPLC a unui amestec de AINS cu detecţie în UV în scopul transferării acestei metode pentru detecţie cu spectrometrie de masă (MS).

MATERIAL ŞI METODĂ

Reactivi utilizaţi: diclofenac sodic (etalon secundar Mark Int'l S.R.L.), ibuprofen, ketoprofen (etaloane secundare Terapia S.A.), piroxicam, meloxicam şi tenoxicam (etalone secundare Labormed Pharma S.R.L.), apă Chromasolv V®Plus pentru HPLC (Sigma – Aldrich), metanol şi acetonitril gradient grade pentru HPLC (Merck), acid acetic p.a., acetat de sodiu p.a.

Aparatură: spectrofotometru UV-VIS Agilent Technologies, cromatograf de lichide 1100 Agilent Technologies, coloană cromatografică StableBond SB C 18 (4,6 x 150 mm, 5 mm), balanţă analitică Kern, pH-metru Hanna Instruments.

Metode: s-au înregistrat spectrele de absorbţie pe domeniul 200 – 400 nm pentru

AINS luate în studiu folosind diverşi solvenţi sau amestecuri ale acestora pe un spectrofotometru tip Hewlett Packard 8453 în cuvă de 1 cm faţă de mediul de dizolvare. S-au înregistrat cromatogramele amestecului unor AINS folosind un HPLC tip 1110 Agilent Technologies, pe o coloană Stable-Bond SB C 18 (4,6 x 150 mm, 5 mm) cu diverse faze mobile, la debite diferite şi cu detecţie în UV.

REZULTATE ŞI DISCUŢII

Analizând datele prezentate în tabelul I se constată faptul că antiinflamatoarele nesteroidiene luate în studiu (diclofenac sodic, ibuprofen, ketoprofen, piroxicam, meloxicam şi tenoxicam) prezintă o solubilitate mai mare în solvenţi polari de tipul apă, metanol, etanol. Acest lucru prezintă importanţă deoarece aceşti solvenţi sunt folosiţi de obicei în compoziţia fazelor mobile utilizate cel mai des în HPLC.

Având în vedere aceste date am înregistrat spectrul de absorbţie în UV-VIS pentru compuşii studiaţi folosind ca solvent pentru dizolvarea acestora apă, metanol, acetonitril şi soluţie tampon acetat pH = 5). Analizând spectrele obţinute (fig. 1) se constată mai multe aspecte. În primul rând, pentru toţi compuşii studiaţi se obţin mai multe maxime de absorbţie, unul în jurul valorii de 200 nm, iar altele la valori mai mari ale lungimii de undă. Având în vedere domeniul de lungimi de undă 200 – 210 nm unde prezintă absorbţie maximă compuşii analizaţi dar şi alte substanţe, am luat în studiu maximele de absorbţie ce se obţin la valori mai mari ale lungimii de undă.

În al doilea rând, maximele de absorbţie alese (tab. II) se găsesc la aceleaşi valori ale lungimii de undă (sau foarte apropiate) în cazul folosirii ca solvent a apei sau a soluţiei tampon pH = 5, în timp ce în cazul folosirii metanolului sau acetonitrilului ca solvent maximele rămân la aceleaşi valori ale lungimii de undă (pentru ibuprofen) sau se deplasează spre valori mai mari (pentru diclofenac sodic) sau mai mici (pentru ketoprofen, piroxicam, meloxicam şi tenoxicam). Pe de altă parte, valorile absorbanţelor la aceste lungimi de undă prezintă şi o serie de modificări (crescătoare sau descrescătoare, în funcţie de compusul studiat şi de solventul în care a fost dizolvat acesta). De exemplu, diclofenacul şi ibuprofenul prezintă absorbanţe mai mari în metanol,

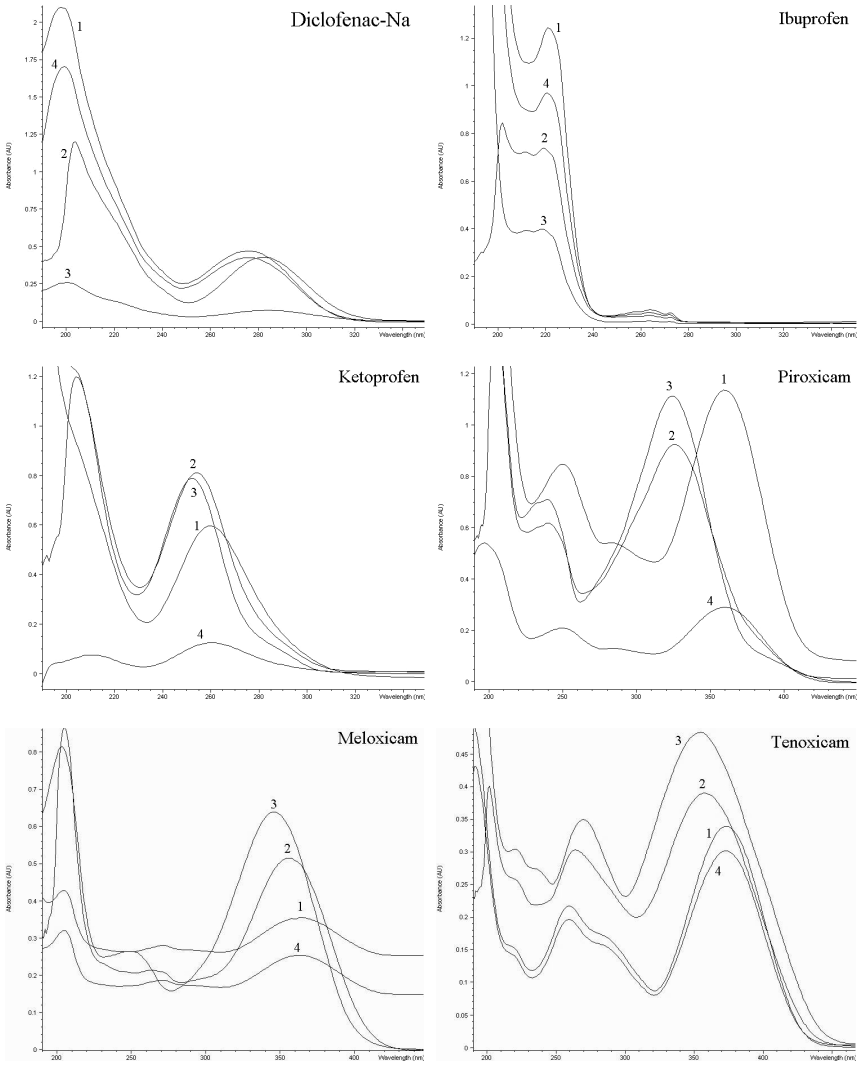

Fig. 1. Spectrele de absorbţie pentru diclofenac sodic, ibuprofen, ketoprofen, piroxicam, meloxicam şi tenoxicam în 1 - apă, 2 - metanol, 3 - acetonitril şi 4 - tampon acetat pH = 5

cei trei oxicami în acetonitril, iar ketoprofenul are absorbanţe asemănătoare în metanol şi respectiv acetonitril. În orice caz, folosind datele obţinute se pot trage o serie de concluzii referitoare la lungimile de undă de detecţie ce vor fi utilizate în cazul separării prin HPLC. Lungimile de undă optime vor fi stabilite abia după ce se va optimiza compoziţia fazei mobile, ştiut fiind faptul că spectrul de absorbţie poate suferi modificări în ceea ce priveşte lungimea de undă ce corespunde maximului de absorbţie funcţie de solvent (în acest caz de compoziţia fazei mobile).

Având în vedere faptul că scopul final urmărit constă în elaborarea unei metode de separare a compuşilor luaţi în studiu prin HPLC este foarte posibil ca faza mobilă să fie constituită din amestecul mai multor solvenţi.

TABELUL II

Maxime de absorbţie pentru diclofenac sodic, ibuprofen, ketoprofen, piroxicam, meloxicam şi tenoxicam în apă, metanol, acetonitril şi tampon acetat pH = 5

Compus studiat	Solvent			
	Apă	Metanol	Acetonitril	Tampon pH 5

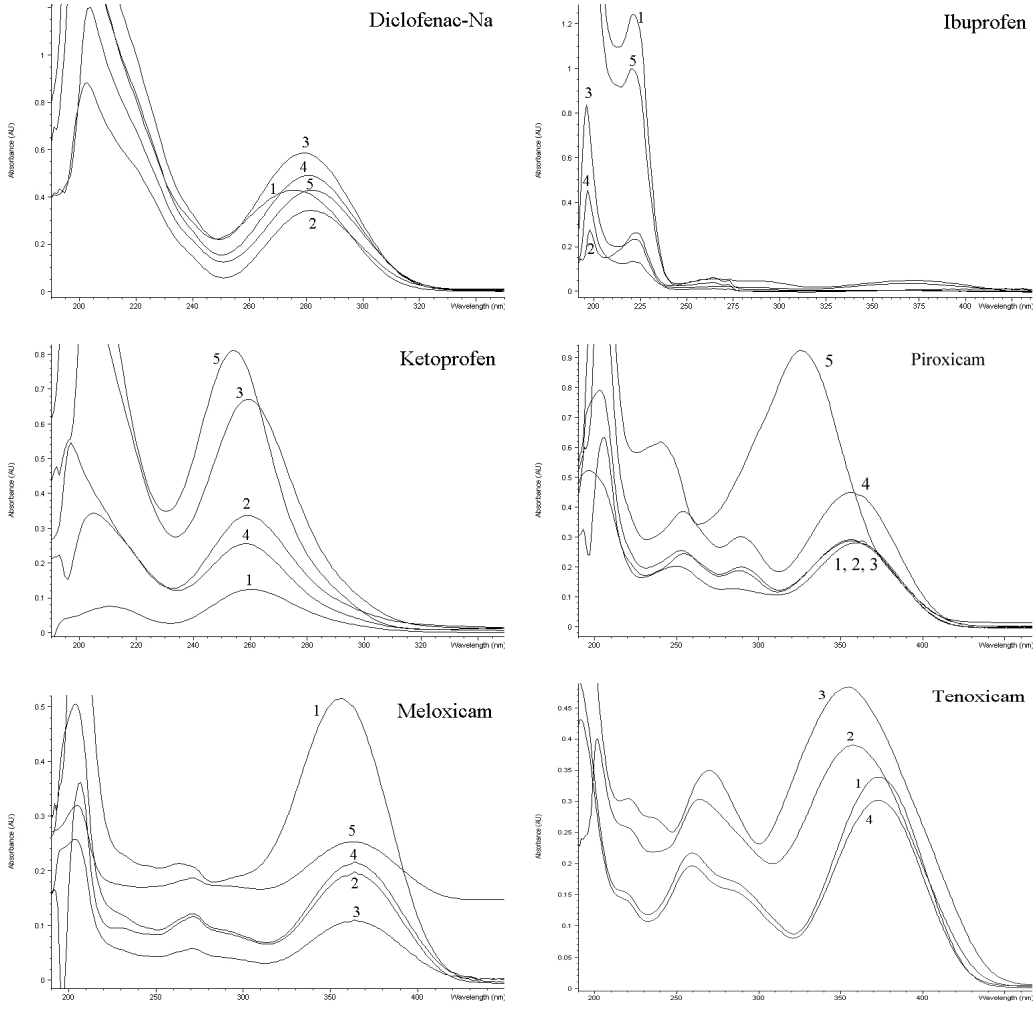

Fig. 2. Spectrele de absorbţie pentru diclofenac sodic, ibuprofen, ketoprofen, piroxicam, meloxicam şi tenoxicam în tampon pH = 5 / metanol (1 - 100/0 ; 2 - 70/30 ; 3 - 50/50 ; 4 - 30/70 şi respectiv 5 - 0/100)

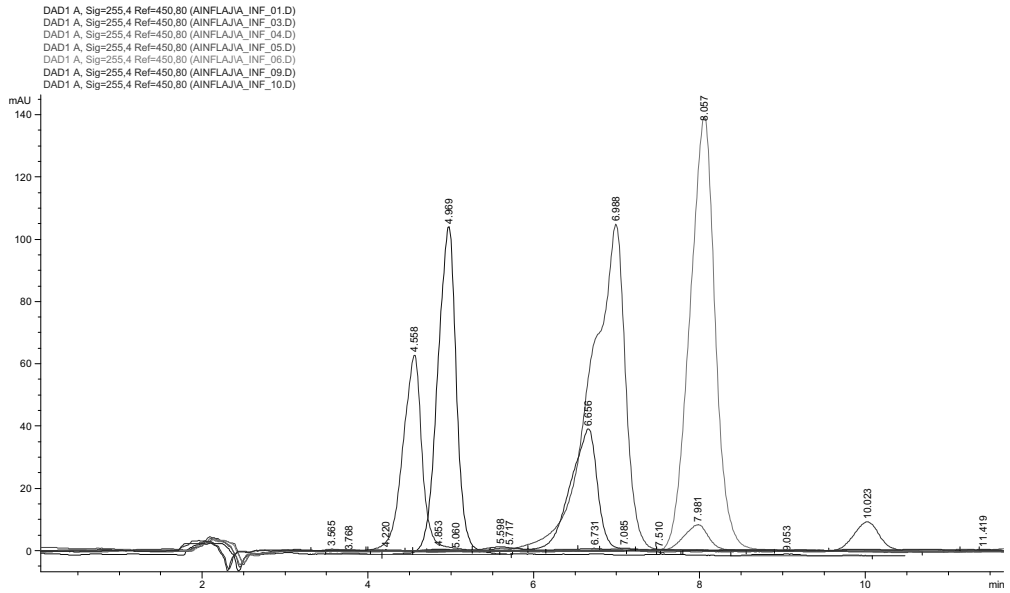

Fig. 3. Cromatogramele obţinute pentru diclofenac, piroxicam, ketoprofen, nimesulid, fenilbutazonă indometacin şi ibuprofen ; fază mobilă formată din acetonitril / metanol / tampon pH 3,6 în raportul 35 / 25 / 40

Având în vederea aceasta, dar şi faptul că aceşti compuşi prezintă o comportare asemănătoare faţă de metanol sau acetonitril, au fost înregistrate spectrele de absorbţie în soluţii metanolice de diferite concentraţii. Astfel, în figura 2 sunt redate spectrele de absorbţie obţinute în cazul în care ca solvent de dizolvare au fost folosite amestecuri tampon pH = 5 / metanol în proporţiile de 100 / 0, 70 / 30, 50 / 50, 30 / 70 şi respectiv 0 / 100.

Analizând spectrele din figura 2 se concluzionează faptul că aceşti compuşi prezintă modifiări semnificative ale absorbanţei în funcţie de raportul în care se află solvenţii (tampon pH = 5 / metanol) şi anume, valori mai mari ale absorbanţei pentru ketoprofen şi piroxicam la dizolvare în metanol 100%, mai mici pentru diclofenac (50%) şi tenoxicam (30%) şi respectiv pentru ibuprofen (0%). Ca şi o consecinţă, este de preferat să se folosească o valoare intermediară pentru raportul dintre faza apoasă şi cea organică astfel încât toţi compuşii să prezinte valori ale absorbanţelor suficient de mari pentru a putea fi decelate spectrofotometric după separarea prin HPLC. În acelaşi sens, având în vedere rezultatele experimentale obţinute, este de preferat să se folosească un amestec de solvenţi organici (metanol şi acetonitril).

Compuşii menţionaţi au fost studiaţi şi la dizolvare în soluţie tampon acetat 0,1M (pH = 3,6) observându-se o uşoară creştere a absorbanţei faţă de soluţii tampon acetat pH = 5, motiv pentru care în determinările ulterioare s-a folosit sistemul tampon acetat cu pH = 3,6.

Un studiu similar a fost realizat şi pentru alte AINS cum sunt nimesulidul, fenilbutazona şi indometacinul.

Având în vedere toate aceste aspecte s-a trecut la separarea cromatografică. Astfel, iniţial s-a folosit o coloană cromatografică de tipul StableBond SB C 18 (4,6 x 150 mm, mm) cu o fază mobilă formată din amestec acetonitril / metanol / tampon pH 3,6 în raportul 35 / 25 / 40 la un debit de 0,7 mL/min analizându-se mai întâi fiecare component în parte. În fig. 3 se prezintă

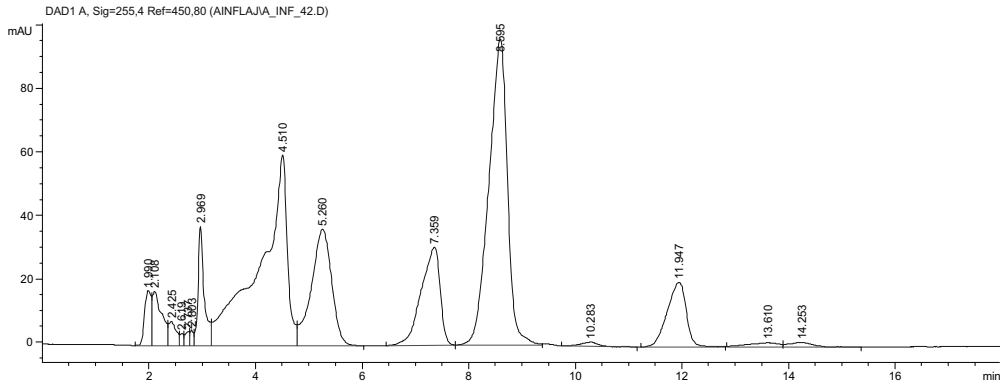

Fig. 4. Cromatogramele obţinute pentru diclofenac, piroxicam, ketoprofen, nimesulid, fenilbutazonă indometacin şi ibuprofen ; fază mobilă formată din acetonitril / metanol / tampon pH 3,6 în raportul 30/30/40 parametri cromatografici, valori prezentate în tab. III.

cromatogramele pentru diclofenac, piroxicam, ketoprofen, nimesulid, fenilbutazonă indometacin şi ibuprofen.

Analizând figura 3 se constată faptul că, în acest caz, compoziţia fazei mobile nu este optimă deoarece există suprapuneri între componenţii amestecului. Acest aspect a fost rezolvat modificând raportul între metanol şi acetonitril din compoziţia fazei mobile. Astfel, pentru o fază mobilă formată din acetonitril / metanol / tampon pH 3,6 în raportul 30 / 30 / 40 se obţine o cromatogramă ca şi cea din figura 4.

Pentru a creşte rezoluţia separării se poate micşora debitul fazei mobile, caz în care, evident, timpul de analiză total creşte. Comparând valorile experimentale obţinute pentru un debit al fazei mobile de 0,7 mL/min şi respectiv 0,5 mL/min se constată că alura spectrelor de absorbţie şi poziţia maximelor de absorbţie nu se modifică, în schimb absorbanţa scade odată cu scăderea debitului fazei mobile ; indiferent de valoarea debitului, înălţimea vârfului rămâne constantă ; odată cu scăderea debitului fazei mobile creşte aria şi înăţimea vârfului. Acest ultim fapt ar putea constitui un avantaj în situaţia în care în proba de analizat nu există toate antiinflamatoarele studiate, deci nu apar probleme în ceea ce priveşte calitatea separării, deoarece o creştere a ariei vârfurilor conduce la o creştere a sensibilităţii de detecţie, deci la o scădere a limitelor de detecţie şi de cuantificare. Trebuie avut însă în vedere şi alţi parametri cromatografici ca, de exemplu, simetria vârfurilor.

Pentru a studia influenţa compoziţiei fazei organice din faza mobilă asupra separării cromatografice a unui amestec de antiinflamatoare nesteroidiene, am ales ca fază mobilă un amestec format din acetonitril, metanol şi tampon acetat. În analizele efectuate, debitul a fost menţinut constant (0,7 mL/min), la fel şi proporţia între faza apoasă şi cea organică (40 / 60). Au fost modificate doar proporţiile de metanol şi acetonitril astfel încât conţinutul în metanol să crească în paşi de câte 10% de la 0 la 30%. Din cromatogramele obţinute se obţin o serie de informaţii referitoare la unii

Analizând aceste date, odată cu creştera conţinutului de metanol în faza mobilă în detrimentul acetonitrilului, se desprind următoarele observaţii :

1) se observă o creştere a timpilor de retenţie, fapt ce poate fi explicat printr-o solubilitate mai mică a acestor componente în metanol decât în acetonitril ;
2) pentru compuşii 1, 2 şi 3, odată cu creşterea conţinutului în metanol din faza mobilă în detrimentul acetonitrilului, se observă faptul că aria vârfurilor este rela-

TABELUL III
Modificarea unor parametri cromatografici în funcţie de raportul dintre metanol şi acetonitril din compoziţia fazei mobile

	50 : 10	10,823	508,5	26,7	0,2924
	40 : 20	12,316	509	18,8	0,4145
	30 : 30	13,873	2397,8	67,4	0,5526

tiv constantă în timp ce înălţimea vârfurilor scade, iar lăţimea creşte ;

3) pentru compusul 4 aria şi înălţimea vârfurilor scad, în timp ce lăţimea creşte ;
4) pentru componenţii 5 şi 6 apare o anomalie, şi anume : aria, înălţimea, cât şi lăţimea vârfurilor nu prezintă o modificare uniformă.

Având în vedere faptul că în proba analizată există un număr de 7 componenţi şi tinand cont de observaţiile (3) şi (4) se poate afirma faptul că din ultimii patru compuşi care eluează, unul suferă o deplasare mai rapidă prin coloană decât ceilalţi trei, în fiecare situaţie în parte obţinându-se picuri suprapuse, deci impure lucru confirmat prin verificarea purităţii picului şi confirmare spectrală. În consecinţă, metoda în cauză nu poate fi aplicată în situaţia în care în proba de analizat se găsesc toţi aceşti patru compuşi.

Pentru justificarea alegerii tamponului acetat din compoziţia fazei mobile în loc de apă argumentul decisiv este că acesta este mai volatil decât alte soluţii tampon, lucru util în situaţia în care metoda de separare prin HPLC cu detecţie UV va fi transferată pentru o detecţie prin spectrometrie de masă.

Pe de altă parte, dacă se analizează parametrii cromatografici pentru două cromatgrame realizate pe faze mobile formate din acetonitril / metanol / apă şi respectiv acetonitril / metanol / tampon acetat în raportul 30 : 30 : 40 se obţin datele prezentate în tab. IV.

Analizând aceste date, dacă se utilizează soluţie tampon în loc de apă, se desprind următoarele concluzii :

TABELUL IV
Modificarea unor parametri cromatografici în funcţie de faza apoasă din compoziţia fazei mobile

Component separat	Faza apoasă	Timp retenţie (min)	Arie pic	Înălţime pic	Lăţime pic
1	apă	4,746	798,6	44,2	0,2588
	tampon acetat	2,971	350,2	37,5	0,1314
2	apă	6,464	913,8	43,8	0,3136
	tampon acetat	4,508	2145,2	60,1	0,4549
3	apă	7,401	720,4	26,1	0,421
	tampon acetat	5,26	975,9	36,7	0,4001
4	apă	10,815	1782,5	40,9	0,6522
	tampon acetat	7,356	781,1	31,3	0,349
5	apă	13,873	2397,8	67,4	0,5526
	tampon acetat	8,594	2387	96,8	0,358
6	apă	15,78	510,8	12,8	0,6203
	tampon acetat	11,946	501,3	20,3	0,3871

- timpii de retenţie scad, ceea ce înseamnă un timp de analiză per global mai mic ;
- pentru primii trei compuşi separaţi, calitatea separării scade, vârfurile obţinându-se suprapuse, din acest motiv un studiu al modificărilor ariei, sau înălţimii picurilor nefiind util ;
- pentru compusul 4 apare o scădere semnificativă a ariei, înălţimii şi lăţimii vârfului corespunzător ;
- pentru compuşii 5 şi 6 aria este relativ constantă, în timp ce se observă o creştere a înălţimii vârfurilor compensată de scăderea lăţimii acestora.
- pentru optimizarea metodei este indicat să se lucreze cu soluţie tampon acetat, dar de o concentraţia mai mică de 0,1M şi cu un pH mai mare de 3,6.

CONCLUZII

Pentru punerea la punct a unei metode de separare ce va fi utilizată la identificarea şi ulterior determinarea cantitativă prin HPLC a unor antiinflamatoare nesteroidiene, după studiul solubilităţii compuşilor ce urmează a fi analizaţi, se pleacă de la studiul proprietăţilor fizico – chimice ce constituie parametrii ce vor fi urmăriţi (în cazul de faţă, absorbanţa în diverşi solvenţi utilizaţi la solubilizarea probelor). Astfel, a fost studiat spectrul de absorbţie al unor medicamente antiinflamatoare nesteroidiene în apă, metanol, acetonitril şi soluţie tampon acetat pentru elucidarea lungimilor de undă optime de detecţie. Având în vedere faptul că în analiza cromatografică nu se utilizează ca fază mobilă solvenţi puri ci mixturi de solvenţi, s-au studiat şi spectrele de absorbţie ale unor amestecuri de solvenţi. După stabilirea unui raport optim între faza apoasă şi faza organică ce vor intra în compoziţia fazei mobile, se alege raportul optim între constituenţii fazei organice, respectiv a fazei apoase, având în vedere solubilitatea fiecărui component în parte, lungimea de undă corespunzătoare maximului de absorbţie, dar şi a parametrilor cromatografici esenţiali (timp de retenţie, aria, înălţimea şi lăţimea picului cromatografic etc.)

În urma tuturor acestor etape a fost elaborată o metodă de analiză prin HPLC a unui amestec de antiinflamatoare. Unul dintre avantajele acestui mod de abordare a problemei constă în costul relativ redus în ceea ce priveşte punerea la punct a metodei HPLC cu detecţie în UV în situaţia în care această metodă de separare va fi transferată pe un sistem ce permite detecţia prin spectrometrie de masă, modalitate de detecţie mai precisă în ceea ce priveşte puritatea picurilor cromatografice, sensibilitatea, evitarea utilizării de substanţe etalon etc.

FRECVENŢA ANOMALIILOR DENTO-MAXILARE CLASA A-II-A ANGLE – ANALIZĂ COMPARATĂ ÎN CADRUL ANOMALIILOR DENTO-MAXILARE ŞI ÎN INTERIORUL CLASEI A-II-A

C. Romanec, Valentina Dorobăţ
Universitatea de Medicină şi Farmacie "Gr.T. Popa" Iaşi
Facultatea de Medicină Dentară
Departamentul de Ortodonţie şi Ortopedie dento-facială

CLASS II ANGLE MALOCCLUSIONS FREQUENCY (Abstract): This study, based on a survey of 1018 children, aged between 6-13 years, from urban and rural areas, aims at estimating the frequency of malocclusions among those patients who required specialized orthodontic treatment. A comparison is made between Class II Angle malocclusions within malocclusions in general. The results show that malocclusions recorded in some specialized orthodontic services reveal significant differences function of the children's provenience, age and sex. **Key words**: CHILD, FREQUENCY OF MALOCCLUSION, CLASS II ANGLE

Anomalia dento-maxilară a devenit astăzi o problemă de sănătate publică datorită caracteristicelor pe care aceasta le înglobează, larga răspândire în populaţie şi tendinţa de creştere (1). Datele din literatură oferă o largă variabilitate a frecvenţei. În Europa frecvenţa variază între 40,8-99% (2,3,4,5, 6,7,8,9,10); pe continentul american este de 75% (11,12); în Asia între 19,6-90% (13); în România între 41-77,6% (14,15, 16,17). Prin urmare, este necesară stabilirea necesităţilor de tratament şi cunoaşterea indicelui de adresabilitate al populaţiei către serviciile de asistenţă medicală stomatologică în general şi cele de ortodonţie şi ortopedie dento-facială în special.

SCOPUL CERCETĂRII

Stabilirea frecvenţei anomaliilor dento--maxilare în funcţie de adresabilitatea către serviciul de asistenţă medicală ortodontică. Identificarea formelor clinice şi a reprezentativităţii malocluziei cls. a-II-a; analiza comparată în cadrul clasei a II-a Angle;

OBIECTIVE

Stabilirea frecvenţei şi a formelor clinice ale anomaliilor dento-maxilare în funcţie de prezentarea la cabinetul de stomatologie.

Cercetarea corelaţiei între frecvenţa tipului de anomalie dento-maxilară cu mediul de provenienţă, vârstă şi sex;

Analiza comparată a clasei II/1, II/2 din punct de vedere al frecvenţei şi gravităţii.

MATERIAL ŞI METODĂ

Studiul se bazează pe datele culese din foile de observaţie clinică întocmite la 1018 subiecţi, cu vârstele cuprinse între 6-13 ani, provenind din mediul rural şi urban, care s-au prezentat pentru prima dată în Clinica de Ortodonţie şi ortopedie dento-facială, UMF Iaşi şi la un cabinet privat, pentru evaluarea stării de sănătate şi tratament de specialitate. După excluderea a 77 de cazuri incomplet identificate, grupul de studiu s-a redus la 941 subiecţi - 486 fete (51,6%) şi 455 băieţi (48,4%). După mediul de provenienţă,

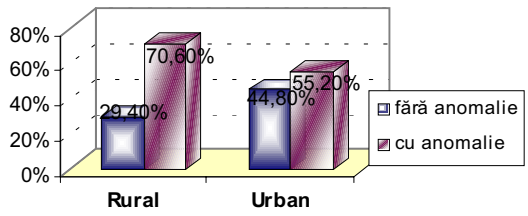

Fig. 1. Repartiţia cazurilor pe mediu de proveniență după prezenţa anomaliei

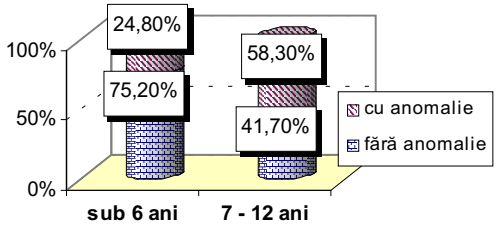

Fig. 2. Compararea frecvenţei relative de apariţie a anomaliei pe grupele 1 respectiv 2 de vârstă pentru sex masculin

73 (7,8%) au fost din mediul rural si 868 (92,2%) din mediul urban. Baza de date a fost constituită în sistem informatizat. Prelucrarea statistică s-a făcut utilizând programul SPSS 16.0 (Statistical Package for the Social Sciences).

Diviziunea lotului a avut în vedere cuprinderea grupelor cheie şi dentiţia/dentaţia: grupa de 6 ani: 222 subiecţi, adică 21,8%; grupa 7-12 ani: 684 subiecţi, adică 67,2%; grupa de 13 ani: 112 subiecţi, adică 11,0%. Analiza datelor s-a făcut pe fiecare din cele trei grupuri, pe lotul total de studiu şi comparaţia între ele. Am urmărit corelaţiile anomaliilor dento-maxilare în funcţie de sex, mediul de proveniență şi grupa de vârstă.

REZULTATE ŞI DISCUŢII

Analiza datelor cu privire la frecvenţa anomaliilor dento-maxilare în funcţie de adresabilitatea la serviciile de sănătate, relevă o frecvenţă a populaţiei infantile din rural de 7,8% şi 92,2% din urban şi o frecvenţă globală a anomaliilor dento-maxilare de 49,2%.

La grupa 7-12 ani frecvenţa cazurilor cu anomalii dento-maxilare din mediul rural este mai mare faţă de cei din mediul urban (fig. 1). Diferenţieri semnificative statistic $p=0,034$.

Analiza anomaliei dento-maxilare ca frecvenţă relativă de apariţie în grupa de 6 ani comparativ cu grupa 7-12 ani pentru băieţi demonstrează că aceasta este mai mare în grupa 7-12 ani (fig. 2), diferenţă semnificativă statistic p este sub 1‰. Acelaşi lucru este constatat şi în cazul fetelor (fig. 3), diferenţa este semnificativă statistic, p sub 1‰.

Compararea frecvenţei de apariţie a cazurilor cu anomalii dento-maxilare pe cele 3 clase de vârstă pe tot lotul cercetat (fig. 4) demonstrează că frecvenţa este mult mai mică la grupa de 6 ani faţă de celelalte 2 grupe de vârstă (fig. 5). Intervalul de variaţie al proporţiei prin metoda Wilson relevă că intervalul vârstei de 6 ani nu se suprapune cu niciun alt interval.

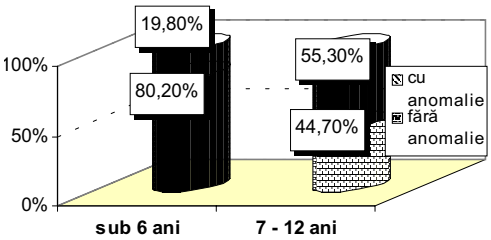

Fig. 3. Compararea frecvenţei relative de apariţie a anomaliei pe grupele 1 respectiv 2 de vârstă pentru sex feminin

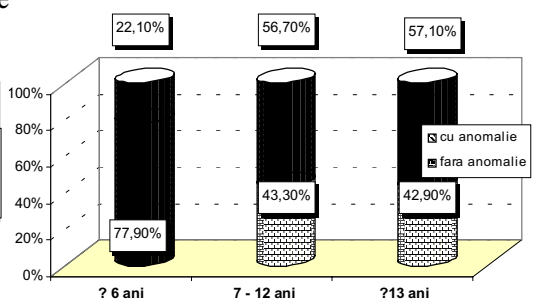

Fig. 4. Compararea frecvenţei relative de apariţie a anomaliei pe clasele de vârstă pentru tot lotul

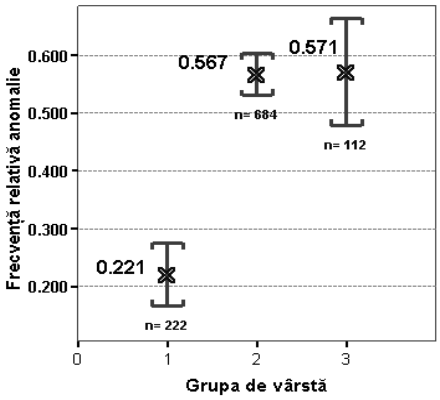

Fig. 5. Frecvenţa relativă a anomaliei pe grupe de vârstă

Eşalonarea tipurilor de anomalii dento--maxilare în funcţie de frecvenţă a fost: malocluzia clasa I (24,6%), clasa a II-a (11,3%) şi clasa a III-a (12,6%). Proporţia cea mai mare a tuturor tipurilor de anomalii se concentrează la grupa de vârstă 7-12 ani.

Cercetând frecvenţa tipurilor de anomalii din cadrul totalului de copii cu anomalii dento-maxilare constatăm diferenţe pe grupele de vârstă (fig. 6), diferenţe semnificative statistic- 0,008.

În grupa 7-12 ani ponderea cea mai mare este deţinută de clasa I Angle urmată de clasa a II-a şi a III-a, pentru ca la vârsta de 13 ani ordinea în funcţie de frecvenţă să fie clasa a I-a, clasa III şi clasa a II-a Angle.

Malocluzia clasa a II-a

Anomalia clasa a II-a Angle ca frecvenţă de apariţie deţine ponderea cea mai mare la grupa de vârstă 6 ani (32,70%), scade în

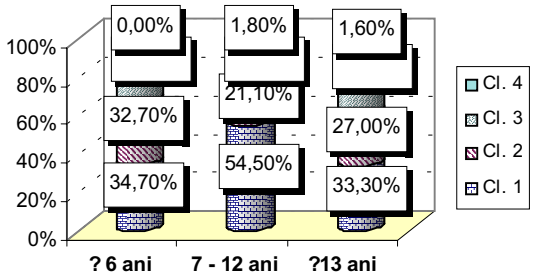

Fig. 6. Distribuţia frecvenţei de apariţie a tipului anomaliei pe clasele de vârstă pentru tot lotul

intervalul 7-12 ani (21,10%), crescând uşor la 13 ani (27,00%).

Distribuţia frecvenţei de apariţie a malocluziei clasa a II-a pe clase de vârstă si sex indică comportamente diferite între fete si băieţi, după cum urmează: băieţii au o frecvenţa de apariţie cea mai mare la grupa 13 ani (34,80%), urmată de grupa de 6 ani (19,00%) şi 16,80% în intervalul 7-12 ani (fig. 7).

Fetele marchează frecvenţa de apariţie cea mai mare la 6 ani (44,40%) şi apoi scade în grupa 7-12 ani (25,00%) şi ajunge la 13 ani la 23,70% (fig. 8).

Simetria

Analiza simetriei în cadrul malocluziei clasa a II-a evidenţiază diferenţieri corelate cu clasa de vârstă şi subdiviziunile clasei a II-a Angle, clasa II_1, II_2.

Vârsta de 6 ani se caracterizează în general prin simetrie pentru clasa II_2 şi într-o mare proporţie clasa II_1 (12% din subiecţi prezintă asimetrie).

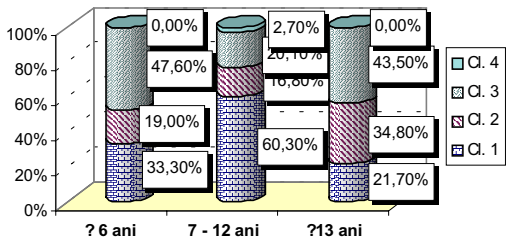

Fig. 7. Distribuţia frecvenţei de apariţie a tipului anomaliei pe clasele de vârstă pentru cazurile de sex masculin

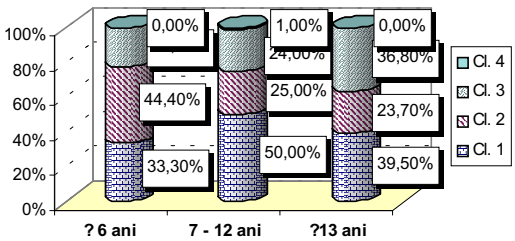

Fig. 8. Distribuţia frecvenţei de apariţie a tipului anomaliei pe clasele de vârstă pentru cazurile de sex feminin

Asimetria creşte pentru clasa II_1 în intervalul 7-12 ani atingând proporţia cea mai mare la 13 ani (29,4%).

Clasa II_2 este afectată de asimetrie în intervalul 7-12 ani, crescând la grupul de 13 ani la 17,6%.

Angrenajele inverse/ocluzia inversă apar în grupele de vârsta 7-12 şi 13 ani, atingând proporţia de 7%.

Ocluzia deschisă a fost identificată la grupele 7-12 şi 13 ani cu o frecvenţă de 2,6%.

Gradul de acoperire a fost la 38,50% din cazuri de 3-6 mm, iar la 3,80% mai mare de 6 mm.

Inocluzia sagitală cuprinsă între 3-6 mm s-a identificat la 20,50%, 57,70% mai mică de 3 mm si doar 1,30% au prezentat inocluzii sagitale mai mari de 6 mm.

Analiza datelor cu privire la frecvenţa anomaliilor dento-maxilare în funcţie de adresabilitate către serviciile medicale evidenţiază o proporţie îngrijorător de mică a populaţiei din mediul rural faţă de populaţia din mediul urban. La fel de neliniştitor este şi faptul că aproximativ jumătate din copiii cu anomalii dento-maxilare s-a adresat pentru consultanţă, dintr-o populaţie în care această patologie depăşeşte 75% şi tendinţa este de creştere. Aceasta înseamnă că o proporţie însemnată din copiii afectaţi de anomalii dento-maxilare nu au fost consultaţi sau nu au solicitat asistenţă medicală în intervalul de vârstă de la mai mic sau egal cu 6 ani până la 13 ani. Dacă o parte din anomalii beneficiază pe parcursul creşterii de autoreglare, fapt raportat în rezultatele unor studii în literatura de specialitate, marea majoritate se va agrava, complicând strategia de tratament, mărind durata acestuia şi preţul de cost.

Cauzele determinante ale precarităţii situaţiei descrise constau în reţeaua de stomatologie pediatrică inexistentă sau săracă în mediul rural şi în urban, nivelul scăzut de educaţie sanitară a populaţiei, absenţa deprinderilor de abordare interdisciplinară în patologia ortodontică cu caracter preventiv şi interceptiv al bolii; mulţi dintre confraţii medici: medici de familie, ORL-işti, pediatri consultă foarte de timpuriu copiii şi ar putea, în condiţia în care ar recunoaşte anomalia, să îi dirijeze către serviciile de specialitate şi poate nu în ultimul rând absenţa evaluării corecte şi la timp a nevoilor de tratament asigurată printr-un proces de dispensarizare corectă făcută de către medicii din sectorul de stat sau privat al copiilor.

Creşterea frecvenţei apariţiei copiilor cu anomalii dento-maxilare la vârsta 7-12 ani se datorează pe de o parte acumulării anomaliilor care s-au permanentizat şi agravat din prima perioadă a dentiţiei mixte cu cele apărute în a doua şi a treia perioadă a dentiţiei. Asistăm la agravarea incongruenţelor dento-alveolare prin înghesuire mai ales la erupţia caninilor, se măresc inocluziile sagitale, apar angrenaje inverse/ocluzii inverse în zona laterală. Tulburările funcţionale şi îndeosebi cele fizionomice devin evidente pentru copil şi membrii familiei ceea ce îi determină să solicite asistenţă medicală, fapt confirmat şi de alte lucrări în literatură.

Frecvenţa de apariţie a anomaliilor dento-maxilare mai mică la grupa de 6 ani se explică prin: simptomele reduse pe care le au anomaliile dento-maxilare la această etapă de vârstă pentru copil şi familie, posibilităţi reduse de a evalua anomaliile potenţiale care se dezvoltă pe baza zestrei ereditare sau sub influenţa unor practici vicioase, tratarea cu superficialitate a unor anomalii evidente sub pretextul rezolvării la apariţia dinţilor pemanenţi, fapt confirmat şi în alte studii. Absenţa dispensarizării din dentaţia temporară bazată pe un examen clinic riguros, dublat de explorări complementare minime necesare în unele cazuri.

Ierarhizarea tipurilor de anomalii dento-maxilare în funcţie de frecvenţă este aceeaşi ca şi în studiile populaţionale, atât la nivelul lotului global cât şi în grupul anomaliilor

dento-maxilare, respectiv clasa I, a II-a şi a III-a Angle, cu diferenţieri în ceea ce priveşte proporţia pe clase de vârstă, sex şi mediu, în sensul scăderii ei. Acest lucru indică nevoia politicilor în domeniul asistenţei stomatologice a copilului, dezvoltarea reţelei de stomatologie pediatrică, care sa vizeze în permanenţă starea de sănătate a copilului preşcolar, şcolar, prin introducerea strategiilor de tratament profilactic, interceptiv şi curativ, bazate pe evaluarea necesităţilor de tratament graduat. Diferenţele care se constată între sexe, în sensul că malocluzia clasa a II-a este mai mare la vârsta de 6 ani la fete faţă de băieţi şi creşte până la vârsta de 13 ani se explică prin procesele de creştere (inclusiv erupţia dentară) mai accelerate la fete, pubertatea mai târzie la băieţi şi interesul crescut al fetelor pentru estetic.

Asimetria, element de agravare a anomaliei dento-maxilare, mai timpurie şi cu tendinţă de creştere de la 6 la 13 ani în subdiviziunea II_1 este expresia dezechilibrelor care apar ca urmare a creşterii progresive a inocluziei sagitale care are drept consecinţă pierderea funcţiei ghidajului anterior în cinematica mandibulară. Dezechilibrele musculare apar pe acest fond al dezechilibrului scheletal şi dentar, apare incompetenţa labială, respiraţia mixtă sau orală, interpoziţia buzei inferioare. Aceste practici creează un impact major asupra echilibrului neuromuscular în ansamblul său. În esenţă anomalia se agravează. În subdiviziunea clasa II_2 Angle asimetria apare în grupa 7-12 ani, creşte către 13 ani, însă în proporţii mai mici decât în II_1 şi se asociază cu angrenajele inverse care apar în aceste perioade în zona laterală, precum şi dezechilibrelor musculare după cum arată şi alte lucrări în literatura.

Dacă prezenţa ocluziei deschise este într-o proporţie redusă ca şi cazurile foarte grave marcate de inocluzii sagitale de peste 1 centimetru sau a ocluziilor adânci cu trauma parodontală trebuie să reţinem necesitatea de tratament ortodontic la limită sau mare de tratament care este impusă de proporţia ridicată a inocluziilor sagitale mai mici ca şi a gradului de acoperire care pot evolua agravându-se în timp.

CONCLUZII

Adresabilitatea la serviciile medicale de specialitate, aşa cum era de aşteptat, ca şi în cazul altor afecţiuni, este mai mică a copiilor din mediul rural faţă de cei din mediul urban. Acelaşi lucru se poate afirma despre copii cu anomalii dento-maxilare faţă de prevalenţa îmbolnăvirilor la nivel populaţional ;

S-au stabilit, de asemenea, corelaţii semnificative statistic între frecvenţa anomaliilor dento-maxilare şi mediul de provenienţă, clasă de vârstă şi sex.

Frecvenţa malocluziei clasa II_1 este mai mare decât cea a malocluziei II_2.

Asimetria apare mai de timpuriu şi cu o frecvenţă mai mare în malocluzia clasei II_1.

NOUTĂŢI

Hiponatremia Şi tratamentul vasoactiv cu Terlipresin

Standardul de tratament al hemoragiei digestive superioare prin efracţie variceală cuprinde în mod obligatoriu tratamentul vasoactiv cu Terlipresin sau Sandostatin. Un studiu realizat recent, pe 58 pacienţi cu hemoragie prin efracţie variceală trataţi iniţial cu Sandostatin, apoi trecuţi pe Terlipresin din cauza resângerării sau a lipsei de control a sângerării, a demonstrat că tratamentul cu Terlipresin determină hiponatremie, cu scăderea sodiului până în 5 mEq/l în 67% ($p=0.002$) din cazuri şi cu peste 10 mEq/L în 36% din cazuri ($p<0.001$). După analiza multivariată a rezultatelor, hiponatremia s-a corelat cu scorul MELD (Model for End-Stage Liver Disease), pacienţii care au avut cel mai mare risc de a dezvolta hiponatremie, fiind aceia care aveau valori ale sodiului la limita inferioară a normalului sau hiponatremie uşoară. În marea majoritate valorile natremiei au revenit la normal după întreruperea tratamentului cu Terlipresin. În unele cazuri hiponatremia a fost atât de severă, încât a determinat manifestări neurologice. Hiponatremia poate fi explicată prin acţiunea terlipresinei la nivelul receptorilor renali de vasopresină tip V2, ipoteză care nu a fost luată în calcul până în prezent. În concluzie studiul trage un semnal de alarmă asupra hiponatremiei induse de Terlipresin, dar şi a monitorizării cu atenţie a pacienţilor cu hemoragie variceală, ştiindu-se că hiponatremia este un factor favorizant al dezvoltării sau agravării encefalopatiei hepato-portale (Solà E, Lens S, et al. Hyponatremia in patients treated with terlipressin for severe gastrointestinal bleeding due to portal hypertension. *Hepatol* 2010 ; 52 (5) : 1783–1790).

RELAŢIA VENITUL FAMILIEI – ALIMENTAŢIE LA UN LOT DE PREŞCOLARI DIN ORAŞUL NEGREŞTI JUDEŢUL VASLUI

Adriana Albu, A.I. Cucu, Andreea Mălaimare, L.L. Indrei
Universitatea de Medicină şi Farmacie "Gr.T. Popa" Iaşi
Facultatea de Medicină
Disciplina de Igienă – Sănătatea Mediului

FAMILY INCOME – NUTRITION CORRELATION IN A GROUP OF NEGREŞTI VASLUI PRESCHOOL CHILDREN (Abstract): Growth and development are influenced by genetic and environmental factors. From the environmental factors, nutrition plays a key role and is income dependent. **Objectives**: Assessing food intake according to family financial status. **Material and method**: A study was conducted on 134 preschool children (ages from 3 to 7 years of age) from a Negreşti kindergarten. Questionnaires were filled by parents for weekly food intake and family financial situation. Statistical analysis used Pearson test. **Results**: According to income the group is structured in: very low income (32.8%), low income (28.3%), average income (26.8%) and above average income (12.1%). The majority of the families provides milk to their children (58.9%), varying from 54.5% (very low income) to 63.1% (low income). Poultry is present in the diet mainly for 2-3 times per week (45.5%) going from 36.8% in low income families to 55.5% in average income families. Daily fruit intake is present in 59.7% of families, varying from 45.4% (very low income) to 68.7% (above average income). Recorded differences have no statistic significance. **Conclusion**: Families income is different but the nutrition provided to children is similar, being strongly influenced by traditional nutritional habits. **Key words**: NUTRITION, PRESCHOOL CHILDREN, INCOME

În decursul vieţii organismul uman trece prin trei perioade reprezentate de: etapa de evoluţie, de stabilitate şi apoi de involuţie. Etapa de evoluţie cuprinde primii 18–19 ani de viaţă şi se particularizează printr-o creştere şi dezvoltare intensă. Aceste doua procese au o evoluţie adecvată doar atunci când copilul are condiţii normale de viaţă. În cadrul acestora includem, în mod deosebit, familia insistând asupra situaţiei sale economice. În familiile sărace calitatea îngrijirilor medicale acordate copiilor este precară, alimentaţia este insuficientă, iar locuinţa insalubră (1). În prezent alimentaţia poate fi în exces, ceea ce expune copilul la riscul apariţiei obezităţii sau insufucientă fiind asociată cu subnutriţia. Obiceiurile alimentare ale populaţiei diferă în variate culturi şi grupuri etnice, în funcţie de alimentele disponibile în zona geografică respectivă. Aceste obiceiuri alimentare se formează în familie în primii ani de viaţă, ulterior ele schimbându-se destul de greu. (2) În acest context, orice program de asigurare a unei alimentaţii sănătoase trebuie să pornească de la cunoaşterea aprofundată a acestor obiceiuri şi să se axeze pe perioadele în care ele se formează.

MATERIAL ŞI METODĂ

Studiul s-a realizat pe 134 preşcolari ce învaţă la Grădiniţa cu program normal nr.1 din Negreşti, jud. Vaslui. Aceşti copii au vărste cuprinse între 3 ani şi 6 luni şi 7 ani fiind incluşi în grupa mică (24 cazuri), mijlocie (33 copii), mare (19 cazuri) şi pregă-

titoare (58 copii). Părinţii au completat un chestionar legat de venitul pe membru de familie şi de alimentaţie. Venitul pe membru de familie a fost încadrat în patru categorii : între 50 – 190 roni (foarte mic) ; între 200 – 490 roni (mic) ; între 500 – 1000 roni (mediu) ; peste 1000 roni (mare). Alimentaţia a fost apreciată cu ajutorul unui chestionar de frecvenţă săptămânală a consumului alimentar (nu consumă – 0 ; 1 dată ; 2-3 ori ; 4-6 ori ; zilnic). Se insistă asupra consumului de lapte, brânzeturi, carne, ouă, grăsimi comerciale, produse cerialiere, legume, fructe şi produse zaharoase. (3,4)

Prelucrarea statistică s- a realizat cu ajutorul testului Pearson.

REZULTATE ŞI DISCUŢII

În general venitul familiei influenţează calitatea alimentaţiei, a îngrijirilor acordate copiilor, a locuinţei. În cadrul acestui studiu vom încerca să identificăm corelaţia ce există între venitul familiilor chestionate şi alimentaţia oferită copiilor. Venitul familiilor chestionate este dominant foarte mic (32,8%) şi mic (28,3%). Nivelul considerat de noi mediu (26,8%) şi mare (11,9%) apare doar în puţine cazuri. Practic în peste 60% din familii nivelul economic este modest, astfel că şi posibilităţile de asigurare a unei alimentaţii echilibrate sunt scăzute.

Consumul de lapte este dominant zilnic (58,9%) sau de 2-3 ori pe săptămână (17,9%) (fig. 1).

Pe tot lotul remarcăm un singur copil (0,7%) ce nu consumă lapte, acesta provenind dintr-o familie cu un venit mare. Indiferent de venitul familiei, în majoritatea cazurilor copii primesc lapte zilnic, astfel că diferenţele constatate sunt nesemnificative statistic ($p > 0,05$). Acest rezultat este surprinzător, el orientându-ne către obiceiuri alimentare asemănătoare, ce nu ţin cont de posibilităţile economice ale familiei.

Brânza este consumată mai ales de 2-3 ori pe săptămână (40,3%) sau 1 dată (26,1%). Există şi situaţii extreme de consum zilnic (15,7%) sau absent (8,9%). Diferenţele nesemnificative statistic ($p > 0,05$) ne orientează tot către existenţa unor obiceiuri alimentare asemănătoare.

Tipul de carne consumat cel mai des de preşcolari este de pui. Domină familiile cu un consum de 2-3 ori pe săptămână (45,5%) şi de 4-6 ori (22,4%). Surprinzător, dar apar şi răspunsuri gen nu consumă (3,7%) sau consumă 1 dată pe săptămână (12,7%). Astfel de răspunsuri apar la toate categoriile de venit (cu excepţia celui mare), diferenţele constatate fiind nesemnificative statistic ($p > 0,05$). Practic, chiar dacă venitul familiei este adecvat consumul alimentar nu cunoaşte o îmbunătăţire majoră fiind dominat de tradiţie, de ceea ce a fost învăţat de la părinţi (fig. 2).

Ouăle sunt consumate în majoritatea familiilor (56,7%) de 2-3 ori pe săptămână,

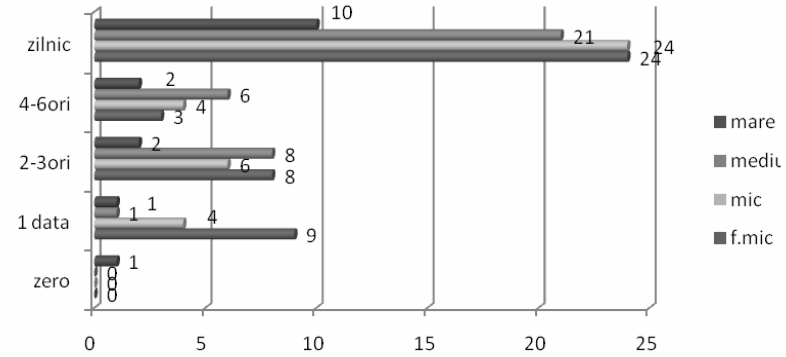

Fig. 1. Consumul de lapte în familiile chestionate în funcţie de venitul acestora

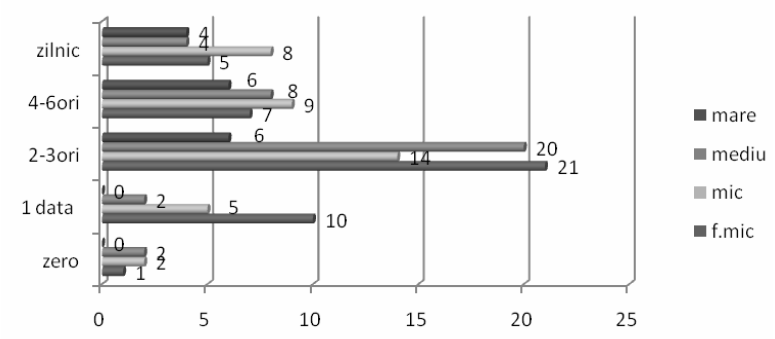

Fig. 2. Frecvenţa consumului de carne de pui

ceea ce corespunde normelor alimentaţiei raţionale pentru preşcolari (1 ou la 2 zile). Îngrijorătoare sunt situaţiile extreme reprezentate de consumul zilnic (3,7%) sau de lipsa aportului (4,5%). Ouăle sunt bogate în proteine şi lipide animale, în elemente minerale şi vitamine fiind un aliment de bază pentru preşcolar. De asemenea, ele sunt relativ ieftine şi uşor de gătit fiind produsele ideale pentru micul dejun. Pe tip de venit rezultatele sunt asemănătoare, diferenţele obţinute fiind tot nesemnificative statistic ($p > 0,05$) (fig. 3).

Grăsimile comerciale sunt de origine animală şi vegetală. Consumul de grăsimi comerciale animale este în majoritatea cazurilor de 2-3 ori pe săptămână (38,05%), dar apar şi situaţii de consum zilnic (6,7%) sau absent (19,4%). Grăsimile comerciale vegetale sunt consumate mai ales zilnic (26,8%) sau de 2-3 ori pe săptămână (26,1%). Sunt îngrijorătoare cele 14,9% răspunsuri de zero ce indică absenţa uleiului/margarinei din alimentaţia copilului. Diferenţele nesemnificative statistic ne orientează către obiceiuri alimentare tradiţionale stabile.

Produsele cerealiere sunt ieftine, dar bogate în proteine vegetale şi glucide, asigurând un aport caloric crescut. Consumul lor în cantităţi prea mari se asociază cu riscul apariţiei obezităţii, îngrijorătoare în acest sens fiind 5,2% cazuri cu aport zilnic. Cel mai frecvent consumul este 1 dată (41,7%) sau de 2-3 ori pe săptămână. Studiul distribuţiei cazurilor în funcţie de venit evidenţiază diferenţe nesemnificative statistic.

Legumele sunt consumate în majoritatea cazurilor (35,8%) de 2-3 ori pe săptămână. Atrag atenţia 8,2% cazuri cu răspuns zero ce indică absenţa legumelor din alimentaţia copiilor (fig. 4).

Total surprinzător răspunsurile negative apar la toate categoriile de venit, diferenţele obţinute fiind nesemnificative statistic. Cumpărarea legumelor nu este o problemă în anumite familii, dar consumul alimentar

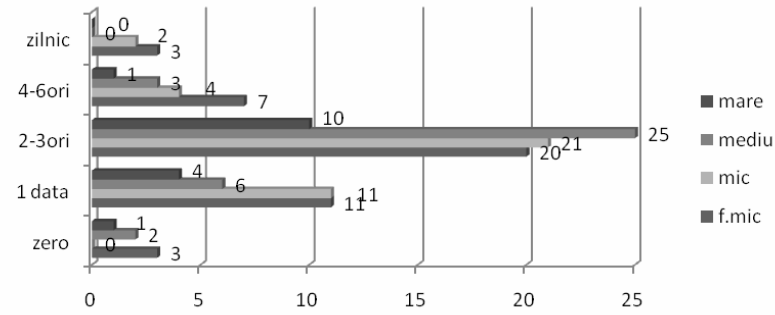

Fig. 3. Consumul săptămânal de ouă în funcţie de venitul familiei

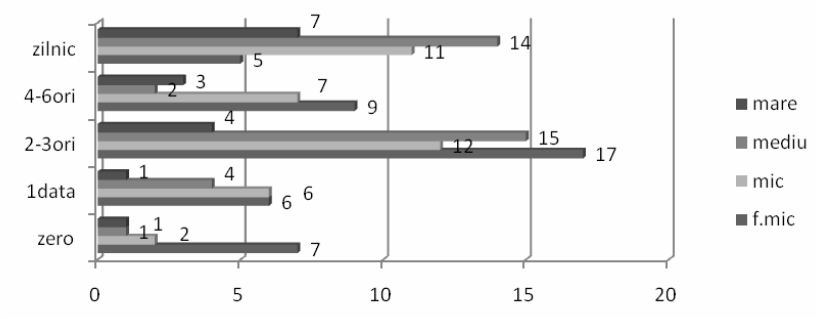

Fig. 4. Corelaţia venit/consum de legume la lotul de studiu

este puternic legat de tradiţia familiei. De asemenea, aceste răspunsuri negative sunt ciudate în condiţiile în care oraşul Negreşti este o colectivitate urbanizată în anii '60, majoritatea familiilor având teren agricol în apropierea oraşului.

Fructele sunt prezente zilnic în alimentaţia a 59,7% din copiii luaţi în studiu. Asigurarea necesarului de fructe nu este o problemă pentru familii, în condiţiile legăturii permanente cu mediul rural. Doar în 0,7% din cazuri consumul este absent.

Aportul de fructe este asemănător în funcţie de venitul familiei ceea ce ne orientează către obiceiuri alimentare stabile. Chiar dacă familia are posibilităţi financiare consumul alimentar respectă strict tradiţia. În condiţiile unor venituri medii/ mari şi a unor informaţii adecvate legate de alimentaţie ar fi de aşteptat ca aportul zilnic de fructe să fie prezent la toţi copii, situaţie ce nu apare în practică.

Produsele zaharoase sunt consumate mai ales zilnic (37,3%) sau de 2-3 ori pe săptămână (29,9%), diferenţele constatate în funcţie de venit fiind tot nesemnificative statistic ($p > 0,05$).

CONCLUZII

Din prezentarea rezultatelor obţinute pe acest lot de studiu putem trage două concluzii foarte importante. În primul rând nivelul economic al familiilor chestionate este precar, remarcându-se 61,1% situaţii de venit foarte mic sau mic pe membru de familie. A doua concluzie de bază este reprezentată de marea stabilitate a obiceiurilor alimentare. Familiile sunt puternic ancorate în tradiţii, astfel că obiceiurile alimentare se schimbă puţin, chiar dacă situaţia economică o permite. În acest context este necesară o intervenţie educativă susţinută pentru a reuşi schimbarea acestora. Înterdicţiile legiferate şi intens mediatizate nu reuşesc să rezolve această problemă.

EVALUAREA LEZIUNILOR DENTARE NECARIOGENE ÎN FUNCŢIE DE INDICII SMITH ŞI KNIGHT

Magdalena Curcă, I. Dănilă
Universitatea de Medicină şi Farmacie "Gr.T. Popa"Iaşi
Facultatea de Medicină Dentară
Disciplina de Dentistică Preventivă

ASSESSMENT OF TOOTH WEAR DEPENDING ON SMITH AND KNIGHT INDEX (Abstract): For the clinical diagnosis of tooth wear Smith and Knight have been suggested the index with the same name, the criteria for the quantification of the hard tissue loss being the size of the area affected and the depth of the defect. The aim of this study was to assess tooth wear depending on Smith and Knight index, on a group of 614 patients. **Material and method**: The criteria for the selection of the patients were the age more than 18 years old and the Smith and Knight index >0. **Results**: The biggest proportion of tooth wear (47.3%) presented the value 2 of the Smith and Knight index. Most of the tooth wear with Smith and Knight index 3 (54.4%) are abrasions, 71.4% of the tooth wear with Smith and Knight index 1 are attritions, and 20.3% of the tooth wear with Smith and Knight index 3 are erosions. High alcohol consumption is associated with deep tooth wear, exposing dentine (value 2 and 3 of the Smith and Knight index). Currently, various indices are used, making the comparison of the results of prevalence studies difficult. **Key words**: SMITH AND KNIGHT INDEX, TOOTH WEAR

FAST RP-HPLC METHOD FOR THE DETERMINATION OF BISOPROLOL

Alina-Diana Panainte, Mădălina Vieriu*, Gladiola Ţântaru, M. Apostu, Nela Bibire
University of Medicine and Pharmacy "Grigore T. Popa" – Iaşi

FAST HPLC METHOD FOR THE DETERMINATION OF BISOPROLOL (Abstract): **Aim:** To develop and validate a fast, robust, isocratic reversed-phase high performance liquid chromatographic method for the determination of bisoprolol in bulk and pharmaceutical formulations. **Materials and method:** Optimum separation of bisoprolol was achieved using as stationary phase a Zorbax SB-C18 column (100×3 mm; 5µm). The mobile phase was a mixture of phosphate buffer (pH = 3.5) and acetonitrile (70:30) with a flow rate of 1mL/min. The UV detection was performed at 225nm. The temperature of the column and autosampler was 25°C. The specificity was assessed by using metoprolol as internal standard. The method was validated in accordance with the current ICH guidelines in terms of linearity, limit of detection, limit of quantification, precision, accuracy, recovery and system suitability. **Results:** The retention time for bisoprolol was 1.158 minute. The calibration graph was linear in the concentration range 5-90 µg/mL. The LOD and LOQ of bisoprolol were 1.63 µg/mL and 4.94 µg/mL, respectively. The intra and interday precision of measurements were lower than the accepted criteria (RSD ≤ 2%). The recovery values of HPLC determination of bisoprolol from tablets proved that none of the excipients influenced the results of the analysis. **Conclusions:** The assay it was found to be accurate, reproducible, sensitive and less time consuming. The proposed method can be successfully applied to quality control studies of pharmaceutical products. **Keywords:** BISOPROLOL, HPLC METHOD VALIDATION, UV-DETECTION.

Arterial hypertension affects many people and is a major risk factor for stroke, myocardial infarction, vascular disease, and chronic kidney disease. Numerous classes of drugs are available to help lower blood pressure: diuretics, beta-blockers, calcium-channel blockers, central agonists, peripheral adrenergic inhibitors, vasodilators, angiotensin-converting enzyme inhibitors, angiotensin receptor blockers. Beta-blockers, also known as beta antagonists, beta-adrenergic blocking agents, or beta-adrenergic antagonists, are drugs that are prescribed to treat several different types of conditions, including hypertension (high blood pressure), angina, some abnormal heart rhythms, heart attack (myocardial infarction), anxiety, migraine, glaucoma, and overactive thyroid symptoms.

There are various types of beta-blockers (1). Bisoprolol fumarate is one of the most widely used beta-blockers in the treatment of cardiovascular diseases such as hypertension, cardiac ischemia and congestive

heart failure. Bisoprolol has been determined in tablets and biological fluids using numerous analytical methods such as high performance liquid chromatography (2, 3), UV-VIS spectrophotometry (4, 5), electrophoresis (6, 7).

The main objective of this work was developing and validating a simple, rapid, accurate and economical method for the determination of bisoprolol using high performance liquid chromatography with ultraviolet detection (HPLC-UV).

MATERIAL AND METHODS

The solvents and other materials were HPLC grade provided by Sigma Aldrich. The bisoprolol fumarate reference substance was provided by Unichem Laboratories Ltd., India. Pharmaceutical formulations containing bisoprolol were purchased from local pharmacies.

An Agilent Technologies 1100 High Performance Liquid Chromatograph with Diode Array Detector, a Kern 770 analytical balance and a Cole Parmer ultrasonic bath were used. The chromatographic separation of bisoprolol was achieved using isocratic elution on a reverse phase stainless steel column Zorbax SB-C18 (100×3 mm; 5µm). The temperature of the column and auto sampler was 25°C. A 50µL sample loop was used. The detector was set at 225 nm.

Preparation of calibration standard. Five miligrams of bisoprolol were weighed and dissolved in distilled water to produce a 100 µg/mL stock solution. Working solutions were prepared by suitable dilutions of the stock solution with the mobile phase. The stock solution of the internal standard (metoprolol) was similarly prepared and then added to the analyzed sample (8).

Determination of bisoprolol in tablets. Two types of bisoprolol tablets produced by two manufacturers were analyzed. The amount of powder equivalent to 5 mg bisoprolol was dissolved into distilled water. The solutions were then filtered through a 0.45 µm Millipore filter in order to obtain a clear solution before injections.

Method validation. Validation of the method was carried out according to The International Conference on Harmonization (ICH) guidelines (9). The linearity was investigated in the 2.5.-120 µg/mL concentration range and the calibration curve was obtained by plotting the peak area values against the bisoprolol concentration using linear regression. The sensitivity of the analytical method was evaluated by determining the detection limit (LOD) and quantitation limit (LOQ) using the calibration curve. The precision and accuracy were assessed in the same day and in different days. The precision of the method was evaluated through standard deviation (SD) and relative standard deviation (RSD) (%), respectively. The accuracy was evaluated through recovery (10). To evaluate the robustness of the developed RP-HPLC method, some small deliberate variations in the optimized method parameters were made. The stability of the bisoprolol solution was assessed by comparing the area for the standard solution preserved for various time intervals with the freshly prepared standard and for sample and standard preparations.

RESULTS AND DISCUSSION

Several parameters were examined for the optimization of HPLC analysis of bisoprolol fumarate. The first step was establishing the composition of the mobile phase and retention time. Various proportions of phosphate buffer: acetonitrile were tested. The most appropriate chromatographic

peak was obtained with a phosphate buffer: acetonitrile 70:30 (v/v) mobile phase. Then the influence of the mobile phase flow rate and pH of buffer on peak normalization were studied. The optimum flow rate was 1 mL/min. The detection was performed at a wavelength of 225 nm as it was determined from the absorption spectra of bisoprolol (fig. 1). The retention time was established at 1.158 min (fig. 2).

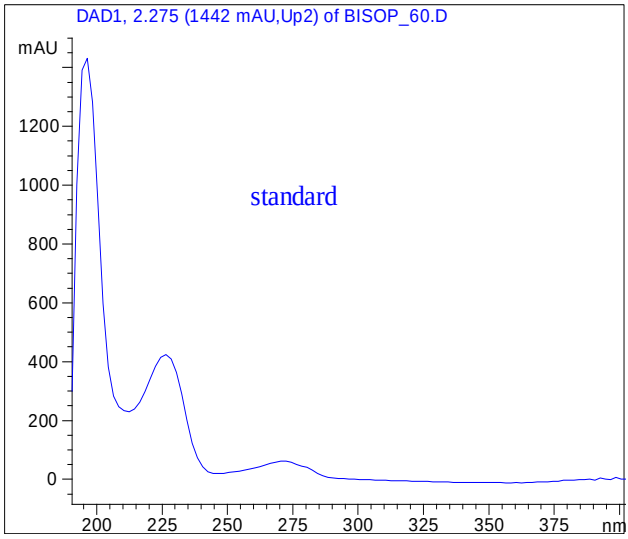

Fig. 1. The absorption spectra of bisoprolol

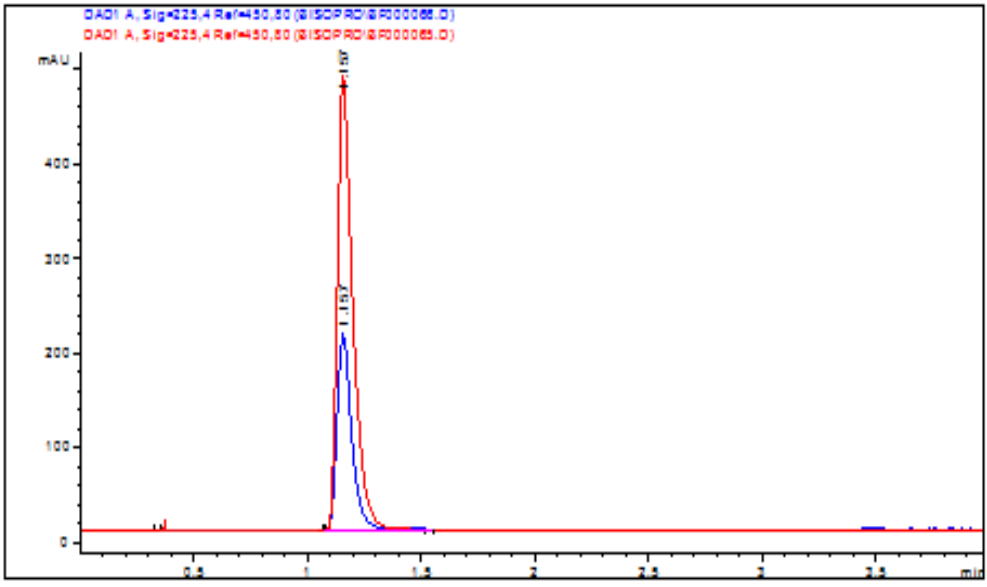

Fig. 2. Retention time of bisoprolol

The specificity was assessed by using metoprolol as internal standard. Chromatogram showed that the method was selective because it had the ability to separate the signal corresponding to bisoprolol from that of metoprolol. For the linearity study, a calibration graph (fig. 3) plotted the concentration against bisoprolol peak area; that graph showed a good linearity in the 0.50-90.0 µg/mL concentration range. Statistical parameters are presented in table I. The LOD and LOQ of bisoprolol were 1.63 µg/mL and 4.94 µg/mL, respectively. Because RSD area ≤ 2% and RSD retention time ≤ 1,5%, we concluded that the chromatographic system was robust (tab. II). The intra and interday precision (tab. III) of measurements were lower than the accepted criteria (RSD ≤ 2%). The proposed method was accurate because maximum value for RSD% was lower than 2% and recovery yield was in the range 97.34-101.04% (tab. IV). The robustness of the method was evaluated by deliberate variation in flow rate (±0.2 mL) and temperature of the column (±5ºC). It was revealed that there were no significant variations in the results of the assay (tab. V).

TABLE IV

Accuracy

Nº	Theoretical concentration (µg/mL)	Pick area	Concentration found (µg/mL)	Recovery (%)
1	40	984.17	40.23	100.58
2		972.83	39.77	100.73
3		985.05	40.27	99.25
4	50	1277.68	52.22	99.74
5		1293.41	52.87	100.20
6		1234.23	50.45	99.24
7	60	1483.26	60.63	101.04
8		1428.82	58.40	97.34
9		1167.45	59.98	99.97
Statistical data			Mean recovery	99.79
			Minimum	97.34%
			Maximum	101.04%
			RSD%	1.05%

TABLE V

Robustness of chromatographic parameters

Nº	Bisoprolol concentration (µg/mL)	Flow rate (mL/min)	Column temperature (ºC)	Average area (n = 3)	Recovery (%)
1	40	0.8	24	998.87	101.06
2		1.0	29	991.68	100.73
3		1.2	34	983.62	99.25
4	50	0.8	24	1213.21	99.74
5		1.0	29	1214.23	100.20
6		1.2	34	1220.02	99.24
7	60	0.8	24	1481.66	100.93
8		1.0	29	1490.28	101.52
9		1.2	34	1487.15	101.31

The influence of interferers such as formulation excipients was evaluated. The recovery values proved that none of the excipients had influenced the results of the analysis.

The experimental results of HPLC determination of bisoprolol in tablets are summarized in table VI.

TABLE VI

Bisoprolol analysis from tablets

Nº	Label claim (mg/tablet)	Concentration found (mg/tablet) (n=3)	Recovery (%)	RSD (%)
1.	P 1 (5)	4.97	99.40	0.77
2.	P 2 (10)	9.95	99.50	0.62

The results of analysis proved that the amount of bisoprolol was in good agreement with the label claim of the formulation, and the mean recovery of bisoprolol as mg/tablet was in agreement with the requirements of the 10th Romanian Pharmacopoeia.

The experimental results of this study showed that the stability of the solution containing bisoprolol was not affected after being brought to the mobile phase and thus the samples can be kept at room temperature for 8 hours; the samples could be submitted to further analysis without suffering degradation, the peak area values for bisoprolol being relatively constant, covariance (%) (CV) in this case having a value of 1.31 and 1.06%, respectively (CV% ≤ 15 %).

CONCLUSIONS

The present study described the development and validation of a novel fast and accurate HPLC method with UV detection for the quantitative determination of bisoprolol in bulk and pharmaceutical formulations. The recovery percentage of bisoprolol was higher than those obtained using other methods. The newly developed method had a much shorted analysis time. It was a simple method that eliminated the need for mass spectrometry. The proposed method may be used in quality control studies of pharmaceutical products.

NEWS

NEXT GENERATION SEQUENCING (NGS) AS A PROMISING TOOL IN FORENSIC GENETICS

The biggest challenge for a forensic geneticist is to obtain sufficient information from trace samples, and thus being able to sequence every DNA molecule in a sample is a very intriguing idea. At the present, the forensic markers are typed using PCR-CE and there are individual assays for autosomal STRs, Y-chromosome STRs, X-chromosome STRs, indels, mtDNA SNPs, autosomal SNPs, Y-chromosome SNPs etc. The most important advantage of NGS is that all these assays could be combined into a single NGS assay. This will save time when dealing with cases where supplementary investigations are necessary and reduce the overall time needed for processing a sample. Another advantage is that the DNA fragments do not need to be separated by lengths in CE, so all the analyzed fragments can be designed to be as short as possible, increasing the chance of typing degraded DNA (Claus Børsting, Niels Morling. Next generation sequencing and its applications in forensic genetics. Forensic Sci Int Genet. 2015 Sep;18:78-89. doi: 10.1016/j.fsigen.2015.02.002).

IN VITRO MEASUREMENT OF TOTAL ANTIOXIDANT CAPACITY OF CRATAEGUS MACRACANTHA LODD LEAVES (Abstract): *Crataegus macracantha Lodd*, family *Rosaceae,* is a very rare species in Europe, and unlike *Crataegus monogyna* is less investigated for pharmacologic activity**. Aim:** To analyze the ability of the lyophilisate of extract obtained from leaves of *Crataegus macracantha Lodd* (single plant at the Iaşi Botanical Garden) to capture free radicals *in vitro*. **Material and methods:** The lyophilisate obtained in Department of Pharmacognosy, Faculty of Pharmacy, "Grigore T. Popa" University of Medicine and Pharmacy Iaşi. The decreased absorbance of chromophore chlorpromazine radical cation in the presence of the lyophilized solutions was studied spectrophotometrically. The indicator radical cation, obtained by oxidation of chlorpromazine by potassium persulfate, has the maximum absorbance at 525 nm. Ascorbic acid was used as a standard antioxidant. **Results:** The absorbance of radical solution was determined after the addition of a certain amount of lyophilisate at different time intervals. The antioxidant activity was calculated using the calibration curve obtained by plotting the variation in radical solution absorbance depending on ascorbic acid concentration. For each ascorbic acid concentration the area under the curve was calculated from plotting the percentage inhibition of the absorbance at two pre-established time intervals. **Conclusions:** The results confirm the antioxidant activity of the leaves of *Crataegus Macracantha Lodd* and by optimizing the proposed analytical methods the antiradical activity can be quickly evaluated with minimal reagent consumption. **Keywords:** ANTIOXIDANT ACTIVITY, CHLORPROMAZINE RADICAL CATION, SPECTROPHOTOMETRIC ANALYSE.

The interest in natural antioxidants, aimed at reducing the harmful action of free radicals on the human body has been steadily increasing. In this context, various methods for assessing the antioxidant activity of plant products in view of their use in pharmaceutical, food, cosmetics industries etc. have been developed (1-4). *Crataegus macracantha Lodd*, *Rosaceae* family, is a very rare species in Europe, and unlike *Crataegus monogyna*, is less studied pharmacologically.

The aim of this study was to analyze the ability of the lyophilisate obtained from leaves of *Crataegus macracantha Lodd* (single plant at the Iaşi Botanical Garden) to capture free radical cations resulting from oxidation of chlorpromazine by potassium persulfate ($CP^{\bullet+}$). These chromophore radicals show maximum absorbance at 525 nm. The color of radical solution is diminished by the presence of antioxidants. Ascorbic acid was used as a standard antioxidant.

MATERIAL AND METHODS

The lyophilisate was obtained at the Department of Pharmacognosy, Faculty of Pharmacy, University of Medicine and Pharmacy "Grigore T. Popa" - Iaşi as follows: 10 g of plant product (leaves) was treated with 100 mL of 70% methanol (v/v); the mixture was stirred for one hour (FALC F-30 ST magnetic stirrer), filtered, concentrated (Rotavapor, BUCHI R-210) and lyophilized (UNICRYO TFD 5505 freeze-dryer).

Of the 10g of plant product 2.62g of crude extract were obtained.

To determine the antioxidant activity the decrease in absorbance of pre-formed radical cation solution ($CP^{\bullet+}$) depending on the amount of lyophilisate was measured spectrophotometrically.

The spectrophotometric measurements were made with a Hewlett Packard 8453 UV-VIS spectrophotometer equipped with multi-diode detector.

Preparing the chlorpromazine radical cation. Chlorpromazine (CP) was oxidized in acidic environment (HCl) by potassium persulfate ($K_2S_2O_8$), forming a radical cation ($CP^{\bullet+}$) with maximum absorbance at λ = 525 nm. For the preparation of the radical 1 mL of 0.01 M chlorpromazine maleate solution was treated with 8.5 mL of 1 M hydrochloric acid and 0.5 mL of 0.001M potassium persulfate solution.

The optimum time interval for the use of radical solution was 20-40 minutes after the addition of potassium persulfate. During this time interval the absorbance of radical solution remained constant.

Sample preparation. About 0.05 g lyophilisate (a) was weighted and dissolved in 10 mL of distilled water. After 30 minutes the resulting suspension was filtered and the obtained solution was diluted with distilled water to final volume of 25 mL.

Working method. To 2 mL radical solution was added a certain amount of lyophilisate solution (v) diluted to 1 mL with distilled water. The absorbance of the solution was measured 10 and 20 minutes after the start of reaction, at λ = 525 nm, 1 cm cuvettes, against water.

The antioxidant activity of the analyzed samples was expressed as molar equivalents (micromolar) of ascorbic acid/gram dry plant product. For this, we used the calibration curve obtained by plotting the variation in absorbance of radical solution depending on the concentration of the standard antioxidant - ascorbic acid (fig. 1).

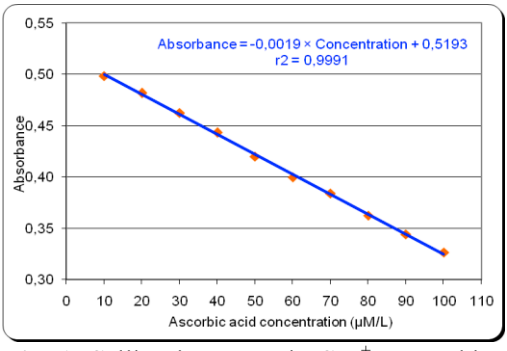

Fig. 1. Calibration curve in $CP^{\bullet+}$ – ascorbic acid system

The method was validated for the linear range of 10-100 μM/L ascorbic acid (5).

RESULTS

For the analyzed samples, the concentration in ascorbic acid was calculated using the straight line equation of calibration depending on the absorbance of freeze-dried solution ($C_{calculated}$). As the final volume of freeze-dried solutions was 1 mL,the concentration of each sample was C = $C_{calculated}$/1000.

Then the result was related to 1 gram dried plant product, taking into account the dilutions made. Measurements were made at 10 minutes (tab. I) and 20 minutes after the start of reaction (tab. II).

Statistical data				**Mean**	**54.76**
				SD	**2.2983**
				RSD	**4.1972%**

The values obtained at the two fixed time intervals demonstrate that quenching of radical reaction by antioxidants from natural product is not completed 10

minutes after the start of reaction (fig. 2).

For this reason, measurements at 20 minutes have RSD values within the acceptable range given while measurements at 10 minutes show a slight deviation from the acceptable range.

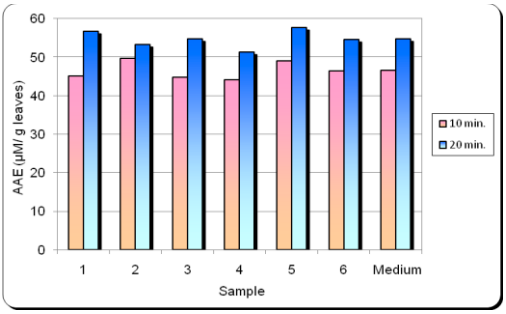

Fig. 2. Micromolar ascorbic acid equivalents (AAE)/1 g *Crataegus macracantha* leaves(10 and 20 minutes after the start of reaction)

In order to eliminate the fluctuations due to changes in absorbance during testing time we used the calibration curve obtained by plotting the area under the curve (AUC) versus ascorbic acid concentration (fig. 3).

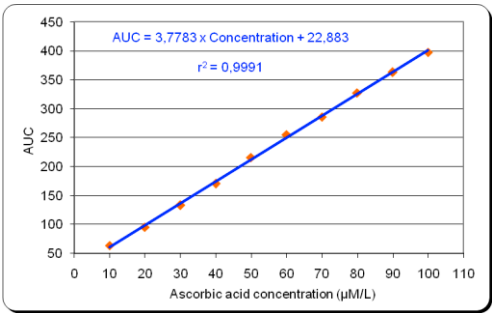

Fig. 3. Area under the curve (AUC) dependent on ascorbic acid concentration

The area under the curve was calculated for each concentration in ascorbic acid (10-100 µM/L) in the graphical representation of the variation of percent inhibition during the fixed time interval (10 minutes and 20 minutes). % Inh = Ar - As / Ar.100, where As–sample absorbance; A_r - radical absorbance (6)

The values obtained by this calculation method for the analyzed samples are given in Table III. The percent inhibition was calculated with Ar = 0.53103.

DISCUSSION

It has been demonstrated that the radical quenching reactions are influenced by the activity of the antioxidant (its reducing

power), its concentration and the time point selected for carrying out the determinations (7-9).

Thus, antioxidants with a higher reducing power will react faster with the radicals, while in case of a decreased reducing power the reaction rate is slower and the time required to complete the reaction of radical quenching will be longer.

The variations in the antioxidant activity of the leaves of *Crataegus macracantha Lodd* within 10-20 minutes after the start of reaction is explained by the presence in the lyophilisate of some compounds with a weaker reducing power, acting on radicals with lower speed.

The values obtained when evaluating the antioxidant activity from the calibration curves AUC- standard antioxidant concentration are situated between the two limit values (from 10 and 20 minutes respectively), the error of determinations being also below the RSD value of the method.

Determination of AUC is a more accurate criterion for the assessment of total antioxidant activity, because it considers both the antioxidant concentration and reaction time, being a parameter for measuring the ability of the antioxidant to capture free radicals, compared to a standard antioxidant, during a fixed time interval.

CONCLUSIONS

Our results confirm the antioxidant activity of the leaves of *Crataegus macracantha Lodd* and by optimizing the proposed analysis methods the antiradical ability of this less studied species can be measured with minimum reagent consumption and in a short period of time. Its antioxidant properties justify a more thorough research aimed at making full use of this plant in therapy.

EPIDEMIOLOGICAL STUDY ON URTICARIA IN CHILDREN (Abstract). **Aim:** The conducted study was focused on identifying children with an atopic background diagnosed with urticaria and also to increase parental responsibility regarding child alimentation, given the impact of allergic reactions (especially those caused by food factors) on the pediatric patient. **Material and methods:** This retrospective study was conducted in 246 patients diagnosed with urticaria admitted to "Sf. Maria" Clinical Pediatric Hospital, Iaşi between January 2012 and December 2013. **Results:** Regarding the etiology of urticaria, the corroboration of the history, clinical and biological data revealed a predominance of urticaria triggered by food factors (54%, 132 cases). Urticaria caused by drugs was identified in 27 (12%) cases, mostly triggered by antibiotics. The analysis of Immunoglobulin E (IgE) blood levels showed elevated levels in 93.75% of the subjects in the age group 0-2 years and 44.44% in children over 6 years old had. Specific IgE analysis for food allergens revealed that β-lactoglobulin, casein and egg white were the most frequently involved allergens for which positive results were obtained. Skin tests (prick tests) showed sensitivity to airborne allergens more frequently than sensitivity to food allergens. **Conclusions:** Our study showed a predominance of urticaria triggered by food factors, given the fact that the prevalence of food allergies increased in the recent decades. History of food allergy is a risk factor in the development of other allergic conditions. **Keywords:** URTICARIA, ATOPIC BACKGROUND, FOOD ALLERGY.

Urticaria is a multifactorial condition with a dermal or hypodermal localization and which appears more frequently in children and youngsters and less frequently in the female population. Data in the literature estimate that approximately 20% of urticaria cases are triggered by the immune-allergic mechanism (activation of mast cells by immunoglobulin E binding, with the release of vasoactive mediators which activate the cutaneous receptors) (1).

In the past decades, statistics have shown an increase in the prevalence of allergic diseases triggered by environmental agents and eating habit modifications (2, 3). Allergic conditions are prevalent amongst the issues of medico-social nature due to the increase in their incidence over the past decades, as well as to their increasing severity, prognostic severity, and high costs implied by the related diagnosis and treatment (4, 5). The involved pathogenic mechanisms are immunological (IgE or non-IgE mediated) or non-immunological

(non-specific activation of mast cells as well as the release of histamine).

Urticaria has a strong impact on the quality of life, especially in children, as it represents an important cause of morbidity, which requires the mobilization of resources to establish an early diagnosis as well as an appropriate treatment.

MATERIAL AND METHODS

A transversal analytical study was conducted in 246 patients admitted to the Iaşi "Sf. Maria" Children Hospital between January 2012 and December 2013. These patients were diagnosed with various forms of urticaria. The patients met the diagnostic criteria (suggestive anamnesis, patient history, general clinical interview and atopic family background).

The patients were assessed based on history data, general physical examination and laboratory investigations: total Immunoglobulin E (IgE), Immunoglobulin E specific to food allergens and airborne allergens and by skin tests (prick test). The anamnesis focused on patient's family history, physiological and pathological history, as well as on dietary habits and history of present illness.

The general physical examination focused on the typical aspect of the urticarial eruption (pruritic papular erythematous plaques of migratory nature) as well as on the associated clinical manifestations: angioedema, gastrointestinal and respiratory symptoms; at the same time, the differential diagnosis included the major pathological entities which may give rise to confusion (erythema multiforma, mastocytosis, urticarial stage bullous pemphigoid).

Statistical analysis was performed by using ANOVA method.

RESULTS

Gender distribution of patients showed a slightly higher frequency of urticaria in males, 129 (52%) patients, compared to females 117 (48%) patients. In terms of area of origin, 136 (55%) patients came from an urban background, while only 110 (45%) came from a rural background. Age-group distribution revealed that the disease was most frequent in the age group 1-5 years, 105 (42.68%) cases, followed by age group 6-10 years, 61 (24.79%) cases.

The distribution of cases according to clinical manifestations revealed that angioedema is the most common symptom associated with urticaria, 78 (31.7%) cases. Regarding the etiology of urticaria (fig.1), the corroboration of history, clinical and biological data revealed a predominance of urticaria triggered by food factors, 132 (54%) cases.

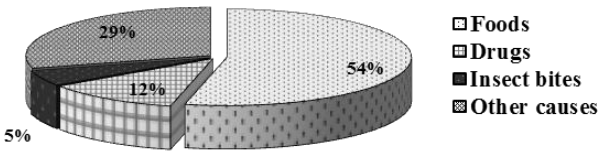

Fig. 1. Cases distribution in terms of urticaria etiology

Drug-induced urticaria was diagnosed in 27 (12%) cases, most frequently caused by antibiotics (14 cases). The most frequently involved were the β-lactam antibi-

otics (penicillins and cephalosporins) followed by the nonsteroidal anti-inflammatory drugs (7 cases). Sensitivity was proved to be prevalent in the case of propionic acid derivatives (ibuprofen, ketoprofen).

In 13 (5%) cases which presented associated angioedema, the cause was insect bites (bees, wasps); the allergen was the hymenoptera venom (Apidae family: Apis mellifera and Vespula).

Given that total serum IgE levels differ according to age, the cases were analyzed by age groups: 0-2 years, 2-6 years, 6 years or more. The distribution of total IgE levels in the whole study group showed that 81 (65%) cases had elevated IgE levels.

A statistical analysis of total IgE showed that the obtained Skewness asymmetry coefficient was 9.719, indicating a tilt to the left of the frequency distribution curve at an early age. The coefficient of vaulting (kurtosis) of 112.471 indicates a distribution suggesting that the sample is not homogeneously distributed around the central value, as there are significant differences between the values of the analyzed interval – their grouping takes place around small values (tab. I, fig. 2).

TABLE I

Statistical analysis of total IgE levels

N	Valid	244
	Missing	0
Mean		122.173

Std. Error of Kurtosis		0.310
Minimum		0.000
Maximum		6244.100

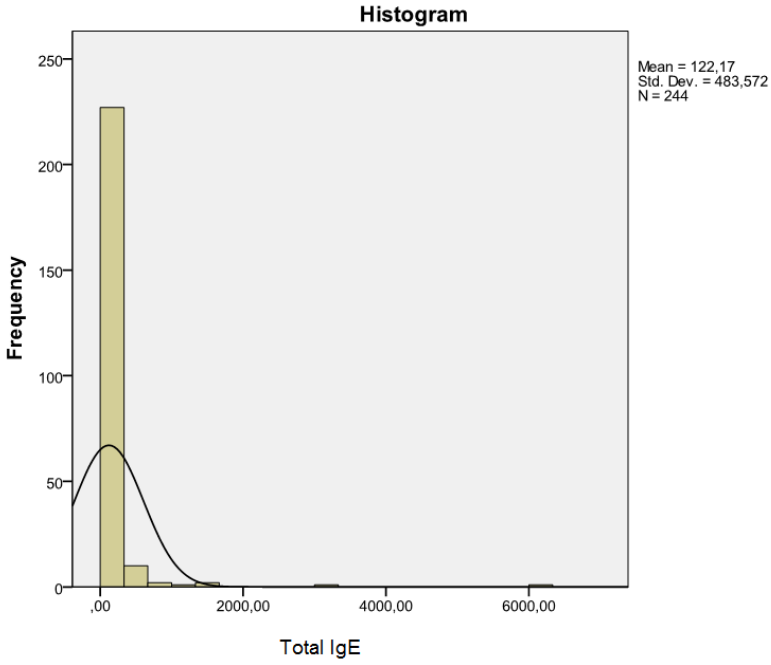

Fig. 2. Distribution of total Ig E level in the study group

The analysis of total IgE levels showed that 93.75% of the children in the age group 0-2 years, 69.23% of the children aged 2-6 years and 44.44% of the children over 6 years had elevated IgE levels.

ANOVA, used to analyze the differences between age group total IgE mean levels indicated a low level (0.896) for age group 2-6 years and normal levels for the other two age groups (6.165 for age group 0-2 years and 8.077 for age group 6-18, respectively), for p values = 0.01, <0.05 for groups 0-2 years and 6-18 years, respectively, p = 0.896 for age group 2-6 years (tab. II). The null hypothesis was rejected, thus there were statistically significant differences between the study groups for a 95% confidence interval (CI).

The diagnosis of food allergy was confirmed by specific IgE and skin tests (prick test). Specific IgE analysis for food allergens revealed that β-lactoglobulin, casein and egg white were the most frequently involved allergens for which positive results were obtained. Skin tests (prick tests) showed sensitivity to airborne allergens more frequently than sensitivity to food allergens.

DISCUSSION

Regarding the etiology of urticaria in the study patients, it was revealed that urticaria symptoms were due to food factors in more than half of the cases, 132 (54%). In children aged less than three years the most common food allergen was cow milk, while in older children hypersensitivity reactions occurred due to consumption of cocoa (chocolate), eggs, peanuts, fish or strawberries. History of food allergy is a risk factor in the development of other allergic conditions, and specialized studies show that food allergy increases the risk of asthma or allergic rhinitis (6).

In the study cases the analysis of family history revealed the presence of family

aggregation, as 15% of cases had at least one family member suffering from polymorphic allergies (asthma, allergic rhinitis, angioedema and drug or food allergy). The clinical events have the tendency of getting worse from one generation to another. Assessment of personal pathology and allergic history revealed that 92 (38%) cases presented at least one previous allergic event. In patients with a history of pathological antecedents, the cases of recurrent urticaria were analyzed; the findings showed that 57 of them had at least one previous urticarial episode: 1 episode (17 cases), two episodes (24 cases) and more than two episodes (16 cases).

Correlation analysis of clinical manifestations and total IgE levels showed that both angioedema and asthma can be considered factors that are associated with a higher degree of severity, assessed by the elevated IgE levels (7). Tracking the dynamics of specific IgE levels can give information on the development of the allergic condition. In children with cow milk allergy, decreased levels of specific IgE compared to allergenic proteins precede the induction of immunological tolerance, and high specific IgE levels are associated with persistent allergic phenomena (8,9). The phenomenon of immunological tolerance occurs at age 7, when the immune mucus barrier becomes mature (secretory IgA) and the antigen-antibody complexes are formed (10, 11).

The analysis of IgE levels in different age groups (0-2 years, 2-6 years and over 6 years) showed that total IgE levels are lower in older children compared to those in young patients. This was also inferred from the dynamic tracking of total IgE and specific IgE in patients with allergic history, since the values decrease after a period as a result of allergen eviction and of specific treatment (12, 13).

CONCLUSIONS

Our study showed a predominance of urticaria triggered by food factors, given the fact that the prevalence of food allergies increased in the recent decades. History of food allergy is a risk factor in the development of other allergic conditions.

NEWS

POLIO THIS SUMMER

In June, an outbreak response assessment took place in the Horn of Africa. The team concluded that transmission in Kenya and Ethiopia has been interrupted, however, undetected low level transmission cannot be ruled out in Somalia. They outlined key measures to continue to strengthen immunity and surveillance, and to put risk mitigation plans in place. Subnational Immunization Days (SNIDs) are planned in Ethiopia from 1 – 3 July and in Somalia for August, with dates to be confirmed. In September, National Immunization Days (NIDs) are planned in Eritrea and Somalia, and SNIDs in Ethiopia, Kenya and Uganda. Five cases of circulating vaccine derived poliovirus type 1 (cVDPV1) have been reported in Madagascar, with dates of onset of paralysis in April and May 2015. The emergency outbreak response is now being intensified to build immunity against the virus in the country, as 25% of children across Madagascar remain un- or under- immunized. One new polio case was reported in the past week, in Afghanistan on the 21 April, when the most recent case had onset of paralysis on 05 May. The total number of WPV1 cases for 2015 is now four. The Technical Advisory Group met in early June and identified that southern and eastern Afghanistan remain at particular risk to polio. The group identified reasons for missed children, which to a great extent are due to remaining operational challenges during campaign implementation. The meeting put forward key recommendations to urgently address these remaining gaps. National Immunization Days in Afghanistan are scheduled on 16 to 18 August using bivalent oral polio vaccine. In other countries, SNIDs are planned across northern Nigeria from 25 – 28 July using tOPV, NIDs are underway in the Central African Republic that are being staggered between end-May and August. NIDs are also taking place in Cameroon on 26 – 28 June. In July, NIDs will take place in Angola and Congo with SNIDs in Central African Republic. National Immunization Days (NIDs) are planned in Sierra Leone for 10 - 13 July. (polioeradication.org, accessed on 30.06.2015)

SECOND MOLAR UPRIGHTING AFTER PREMATURE LOSS OF MANDIBULAR FIRST PERMANENT MOLAR- CASE REPORT (Abstract): **Introduction:** Uprighting a tipped molar by using an uprighting spring is a fundamental orthodontic treatment technique. Following a weak anchorage done only by the anterior teeth the permanent lower second molar will rotate around its center of resistance, and besides the distalizing movement will occur its extrusion. Following the reaction, the mandibular anterior teeth will have a movement of intrusion. All these elements will lead to anterior open bite. Correction of vertical problems has become easier with the advent of mini-implants. **Case presentation:** U.I patient aged 24 years presenting for aesthetic and functional disorders. Clinical examination reveals intraoral Class I molar malocclusion on the right sight, upper narrowing arch with a slight overbite, and the both permanent first molars on the left side lost prematurely. The tooth 37 is inclined at 60^0 degrees to the plane of occlusion. To avoid front opening occlusion we used an orthodontic miniscrew inserted between the canine and the first premolar on the same side to achieve the second molar up righting. Lower second molar uprighting was achieved without unwanted movements in anterior mandibular region and without molar extrusion. **Conclusions:** Using mini implants in uprighting a tipped molar will achieve the desired tooth movement and will reduce the number of unwanted side effects and eventually to improve patient's esthetics. **Keywords:** SECOND MOLAR UPRIGHTING, PREMATURE LOSS, MANDIBULAR FIRST MOLAR, ORTHODONTIC MINISCREW

The first permanent molar has been reported to be the most caries prone tooth in the permanent dentition. More than 50% of children over the age of 11 years have some caries experience in this tooth (1, 2, 3). The early loss of permanent first molars is a routine problem in the orthodontic clinic and results in mesial inclination of the second molars. Especially the early loss of the lower first permanent molar should be immediately addressed by prosthetic replacement or orthodontic space closure as it may lead to functional and anatomical disturbances. The sequelae of events include distal migration of premolars, extrusion of the antagonist molar, premature contacts in centric relation, occlusal interferences during lateral and protrusive movements. In addition there is a difficulty in prosthetic adaptation when the inclina-

tion is excessive. Mesial inclination favors the appearance of vertical bone defects and infra-osseous pockets in the mesial region of molars (4, 5).

Molar uprighting into its correct position leads to the normalization of functional and periodontal occlusion situation, enabling the roots to be positioned perpendicular to the occlusal plane so that they are better able to resist to occlusal forces, in addition to facilitating the plane of insertion of the prosthesis parallel to the long axis of the tooth (6). Various conventional orthodontic approaches were used to achieve such a movement, but all have been plagued to a greater or lesser extent by the following issues: extrusion of the molar to be up righted, unwanted movement of the anchorage unit, the need for bulky appliances, the frequent need of accessories to strengthen anchorage, and long treatment time (7).

With the advent of the use of miniscrews as orthodontic anchorage, molar uprighting procedures have become simpler, with more predictable results, and since there is no need to use other teeth as anchorage, there is better control of undesirable effects (6).

The aim of this study is to describe a method for molar uprighting with the use of a titanol spring supported on a messially placed miniscrew.

CASE REPORT

Therefore we want to present a case that presented in the clinic of Orthodontics and dento-facial orthopedics in the Ambulatory Pediatric Dentistry from Iasi, Romania. U. I. patient aged 24 years presenting for functional disorders. The extra-oral examination (fig. 1) revealed an oval shape of the face, a mesocephalic head shape, a mesoprosopic face, and a mild convex profile. Facial changes occur hyperdivergent profile and an acute naso-labial angle. The patient showed a good range of mandibular movements and no temporomandibular-joint symptoms.

Fig. 1. Extraoral aspect-before treatment

Clinical examination revealed intraoral Class I molar malocclusion on the right sight, upper narrowing arch with a slight overbite, and the both permanent first molars on the left side lost prematurely. The space for 26 and 36 decreased due to mesial inclination and migration of the second molars. Tooth 16 was covered by a metal-ceramic crown (fig. 2).

Orthopantomogram (OPG) examination revealed good root canal treatment on tooth 16. All wisdom teeth were present.

The OPG was processed by tracking the following structures (fig. 3):

-*the occlusion plane* – line tangent to the vestibular cusps tips of premolars and the canine tip on the same side;

-*the axis of lower second permanent*

molar – the line passing through the center of the crown and the center of radicular bifurcation.

The tooth 37 was tipped at approximate 60^0 degrees to the plane of occlusion (fig. 3). Second permanent molar from the four quadrants had an inclination of 78 ° to the plane of occlusion.

Cephalometric analysis using *Onyx Ceph*^{R} software revealed a Class I skeletal (∠ ANB=2.2^0) with a hyperdivergent profile ∠GoGn/SN=35^0.

Fig. 2. Intraoral aspect-before treatment

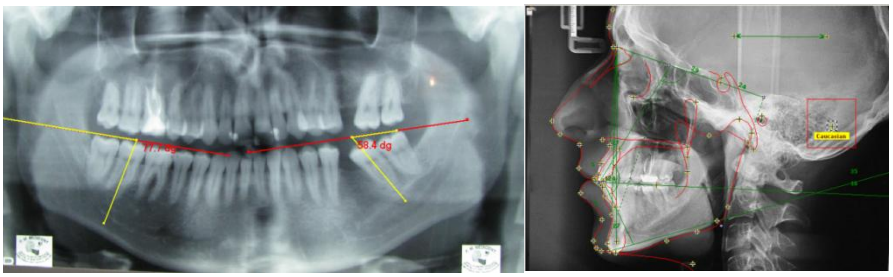

Fig. 3. OPG and Cephalometry - before treatment

The patient's chief concern was the difficulty of achieving chewing on the left side. There were two treatment alternatives for this case:

(1) Opening the space, uprighting and distalization of upper and lower left molars and implant/prosthetic replacement of the left first permanent molars or (2) orthodontic space closure by uprighting the second and third molars and translating them into mesial space.

Because the patient did not want a prosthetic/implant replacement he accepted an orthodontic treatment. The treatment plan included a surgical palatal expansion (fig.4), extraction of 18 and 48, uprighting the second permanent molar and a full fixed appliance therapy with space closure.

We use a prefabricated superlastic Sander spring (Memory-Titanol-Fefer; Forestadent,

Bernard Förster GmBH, Pforzheim, Germany) to achieve the second molar uprighting. Because the patient had a slightly hiperdivergent profile (∠GoGn/SN=35^0) and to avoid front opening occlusion we used a titan orthodontic miniscrew (8 mm, Ortho-Easy®Pin Forestadent®) inserted between the canine and the first premolar on the lower left side as for anterior anchorage (fig. 5).

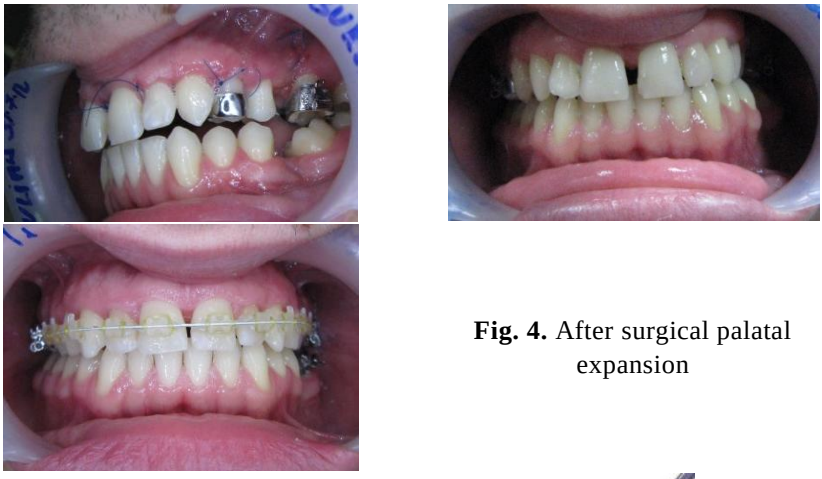

Fig. 4. After surgical palatal expansion

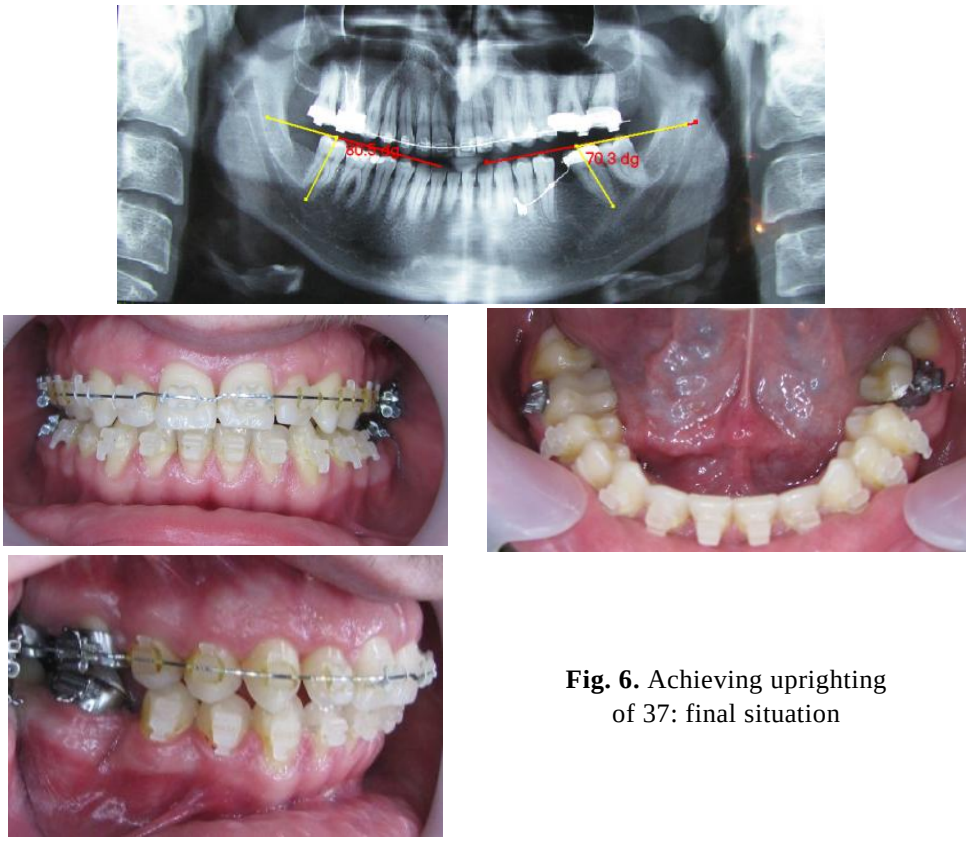

Fig. 6. Achieving uprighting of 37: final situation

DISCUSSION

Permanent first molars are the first permanent teeth to erupt into the oral cavity. They have been quoted as the most caries-prone tooth in the permanent dentition leading to their early loss, probably as a result of their early exposure to the oral environment (1, 2). Loss of a first permanent molar should be immediately addressed by prosthetic replacement or orthodontic space closure as it may lead to functional and anatomical disturbances (4). The second and third molars from that side will incline and rotate, canine and premolars will move distally into the molar space, and the opposing first molar will extrude. Correction of these problems is the biggest challenge to the orthodontist (5).

The ideal solution of six years molar syndrome is protraction of the second and the third molars and toothless gap closure without biological sacrifice. The procedure is not simple, as these strong roots and a significant path that follows the apex, if we take into account initial second molar inclination. In a second molar inclination of 30^0-40^0 correspond to 11 mm travel only apical-uprighting recovery (8) (fig. 7).

The optimal molar uprighting technique for most situations in adults should thus apply an intrusive force to the molar crown, within an inflammatory- free environment. A safe and simple method to achieve such conditions is to use the prefabricated superlastic Sander spring (Memory-Titanol-Fefer; Forestadent, Ber-

nard Förster GmBH, Pforzheim, Germany). Although the prefabricated Sander spring is a simple and effective method for mandibular molar up righting, the method can involve unwanted movements in anterior mandibular region (9) (fig. 8).

Lee et al. have promoted the use of miniscrew as direct anchorage changing the mini implant position in order to obtain two different types of force. The miniscrew can be positioned in the retromolar area, where it acts as a fulcrum for the traction by pulling distally to the second molar (10). This position of the miniimplant can be used in mild tipped molars cases with mesial inclination of the crown, because it generates a sufficient effective uprighting moment to allow the complete straightening of the molar. Instead in moderate to severe tipped cases, the generated moment is too small to produce a sufficient straightening of the tooth (11). For this reason it is essential to consider the possibility of placing the mini implant mesially to the tipped tooth so as a thrusting action force from mesial to distal in generated (12). To avoid front opening occlusion we used in this case an orthodontic miniscrew inserted between the canine and the first premolar on the same side to achieve the second molar uprighting. Achieving uprighting of 37 the slightly hiperdivergent profile remained constant ($\angle GoGn/SN=35^0$).

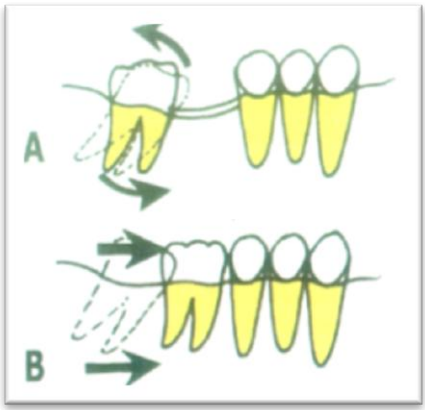

Fig. 7. Closing gaps steps left by the absence of a first lower molar

Fig. 8. Consequences of molar uprighting with poor anterior anchorage and molar extrusion

CONCLUSIONS

In this article we used a miniimplant in uprighting a tipped molar to achieve a desired tooth movement and to reduce the number of unwanted side effects and eventually to improve patient's esthetics. It is necessary a proper clinical, radiological, and biomechanical evaluation and a thoughtful selection of the best orthodontic devices to grant successful treatment results.

PINUS CEMBRA L.: HISTO-ANATOMICAL FEATURES, ANTIOXIDANT ENZYME ACTIVITIES AND HEAVY METAL CONTENTS OF LEAVES AND LONG SHOOTS (Abstract) **Aim**: This study aimed to investigate the histo-anatomical features of the long shoots and leaves (young and mature) of *Pinus cembra* L.. The activity of antioxidant enzymatic systems and the content of heavy metals were also evaluated. **Material and methods**: For the histo-anatomical study, the cross-sections were performed by usual techniques. The activity of antioxidant enzymatic systems (superoxide dismutase, catalase and peroxidase) was evaluated by spectrophotometric methods. The content of heavy metals was determined by atomic absorption spectroscopy. **Results**: The cross-section through the long shoots shows many resiniferous canals and a periderm of variable thickness. The leaf has a triangular shape and only two vascular bundles in the inferior and upper levels. The highest level of superoxide dismutase activity (344.90 U/mg protein) was determined in the long shoots collected from a cembran pine in Vatra Dornei, while the highest level of peroxidase activity (7611.11 U/mg protein) was found in the leaves collected in Calimani Mountains. Cd level in all samples was under the quantification limit. Higher levels of Pb were determined in the long shoots (3 µg/g dry weight for the vegetal material collected in Vatra Dornei and 2.86 µg/g dry weight for the vegetal material collected in Calimani Mountains). **Conclusions**: *Pinus cembra* L. leaves show specific elements of subgenus *Strobus* (a triangular shape of the cross section, one single vascular bundle and two resiniferous canals). The results obtained for the superoxide dismutase and peroxidase activities corroborated with those obtained for the heavy metal contents indicate that antioxidant enzymes play an important role in the protection of *Pinus cembra* L. against exogenous stress factors. **Keywords**: *PINUS CEMBRA* L., LONG SHOOTS, LEAVES, HEAVY METALS, ANTIOXIDANT ENZYMES

Pinus cembra L. (cembran pine) is a resinous conifer which belongs to subgenus *Strobus* (*Pinaceae*). It is a species that grows in the alpine and subalpine regions,

at the upper limit of forest area (1350 - 1880 m altitude in the Northern Carpathian Mountains and 1350 - 1986 m altitude in the Southern Carpathians). In these regions, the climate is characterized by a high difference between winter and summer and also between day and night temperatures. Cembran pine is well adapted to high altitude continental climate, frosts and ample temperature oscillations (1).

Environmental factors such as high or low temperatures, drought, radiation, air and soil pollution generate reactive oxygen species (ROS) in plant tissues. The plants outspread in the mountain area are often exposed to large variations of both temperature and radiation (2). Antioxidant enzymatic and non-enzymatic systems protect plants against ROS. The most studied enzymes involved in the protection against oxidative stress are superoxide dismutase, catalase and peroxidase.

Soil and water contamination with heavy metals has become a severe environmental problem regarding the potential ecological consequences. Heavy metals from different sources (industry, mining, agriculture) have an increased tendency of accumulation leading to negative consequences on plants, animals and humans. In plant kingdom, they affect physiological mechanisms (photosynthesis, transpiration), cause protein denaturation and affect the permeability of cell membranes. It is known that some metals (Fe, Mn, Mo) are micronutrients and play an important role in the normal cell development. On the other hand, As, Ag, Cd, Pb and Sb are toxic for plants and affect cell metabolism (3).

As *Pinus cembra* L. is frequently exposed to different stress factors in mountain and urban areas, the aim of this study was to evaluate the activity of antioxidant enzymatic systems (superoxide dismutase, catalase and peroxidase) and quantify some heavy metals in leaves and long shoots. A histo-anatomical study on the leaves and long shoots of cembran pine was also performed.

MATERIAL AND METHODS

Histo-anatomical study involved the microscopic examination of cross-sections through the long shoots and leaves (young and mature). The plant material was collected from a cembran pine in Calimani Mountains in September 2009 and identified by specialists from *Anastasie Fatu* Botanical Garden Iasi. The vegetal material was preserved in 70% (v/v) ethanol. Manual sections were made by using a botanical razor and a hand microtome (4). The cross sections were colored with ruthenium red and iodine green and analyzed using a Novex (Holland) microscope with a Canon A540 camera.

The evaluation of ***antioxidant enzyme activities*** was performed on leaves and long shoots collected from two different locations (Calimani Mountains at approx. 1650 m altitude – codified CM and Vatra Dornei City, Suceava County – codified VD) in June 2011. The plant material was kept at -20°C until biochemical studies. ***Superoxide dismutase (SOD) activity*** was measured according to the method of Winterbourn *et al.* with minor modifications (5). ***Catalase (CAT) activity*** was evaluated using the method of Sinha, cited by Artenie *et al.* (5). ***Peroxidase (POD) activity*** was measured according to the method of Gudkova and Degtiari, cited by Artenie *et al.* (5). The specific activity of all enzymes was calculated using protein content determined by Bradford method (6). All determinations were made in triplicate. The results were

expressed as mean ± standard deviation.

For ***quantification of heavy metals*** in leaves and long shoots, the samples were analyzed using an atomic absorption spectrometer (burner length of 100 mm) (ContrAA 300, Analytic Jena, Germany). The wavelengths used for each metal were: 213.85 nm (Zn), 324.75 nm (Cu), 217 nm (Pb), 228.8 nm (Cd). The limits of detection and quantification were calculated for 0.5 g of sample and a final volume of 25 mL.

RESULTS AND DISCUSSION

Histo-anatomical study

The cross section through the long shoot is circular (fig. 1A). The periderm is thick and persists only in some areas, in others being exfoliated together with a part of bark (fig. 1B). Many resiniferous canals are visible in the bark and wood rings (fig. 1C). The pith is star-shaped due to numerous groups of cells that penetrate the wood. Some cells have cellulosic walls, and others have lignified ones (fig. 1D).

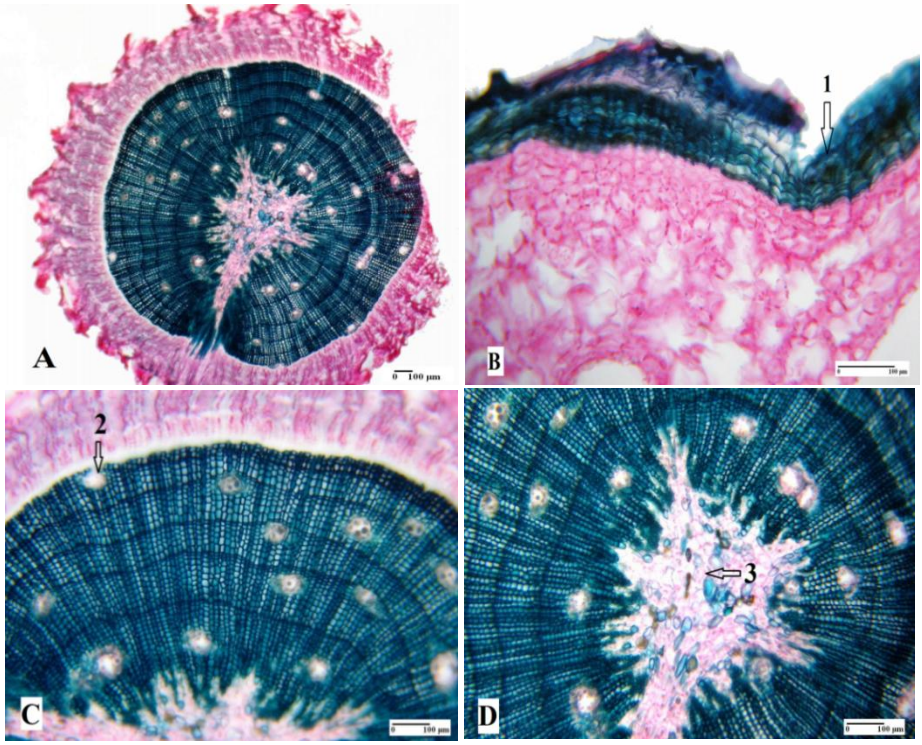

Fig. 1. The long shoot of *Pinus cembra* L.: cross section
A-overview; B-periderm; C-resiniferous canals; D-pith
(1-periderm; 2-resiniferous canal; 3-pith)

The leaves were cross sectioned on different levels from the top to the basis. In cross section, the leaves of *Pinus cembra* L. show a triangular profile.

In the cross section through the inferior level of the young leaf, the epidermis with isodiametric cells and thin walls is observed (fig. 2A). The homogenous meso-

phyll is represented by cells with sinous walls. In the transfusion tissue a vascular bundle with phloem and a very extended xylem is visible (fig. 2B).

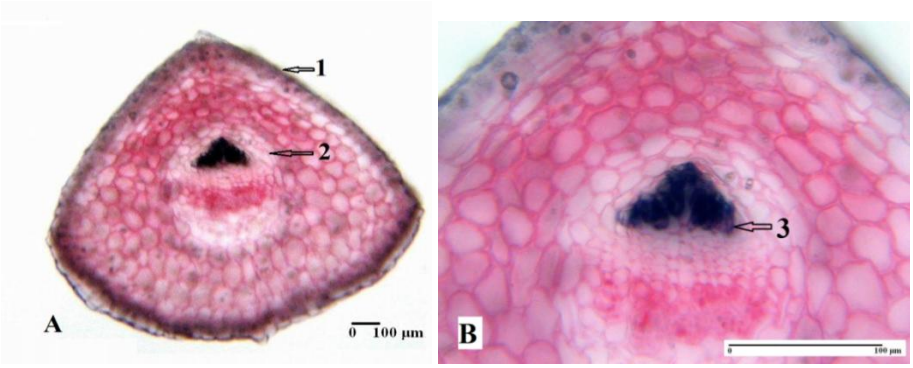

Fig. 2. The young leaf of *Pinus cembra* L.: cross section through the inferior level
A-overview; B-vascular bundle
(1-epidermis; 2-median vein; 3-vascular bundle)

In the cross section through the middle level of the young leaf, the epidermis is unilayered and consists of isodiametric cells having all walls thickened, while the lumina is almost circular; the external walls are covered by a thin cuticle and epicuticular wax (fig. 3A). Under the epidermis, there is a hypodermis represented by one-two layers of fibrous cells with polygonal shape having uniformly thickened and lignified walls. This hypodermis is continuous, interrupted only by stomata (fig. 3B). The stomata in the epidermis of *Pinus cembra* L. leaves (placed deeper than the surrounding epidermic cells) have a typical xeromorphic structure (fig. 3A).

The mesophyll is a homogenous tissue consisting of large septate cells (especially those placed near the hypodermis) with not too deep septums (fig. 3B).

In the mesophyll there are three resiniferous canals situated in the corners of the leaf. The central cylinder consists of a colorless parenchyma where there can be distinguished a pericycle, two collateral vascular bundles, fibers and a transfusion parenchyma. The pericycle consists of large parenchymatic cells, adjacent to the endodermis. The xylem of the vascular bundles shows numerous vessels with strongly thickened and lignified walls. The phloem has a few layers of sieved tubes, surrounded by large cells of phloem parenchyma. The vascular bundles are closed one to the other forming a single conductive unit (fig. 3C). The external part of the phloem is surrounded by a region of cellulose fibers similar to those in the hypodermis. The transfusion tissue represents an anatomic feature of the Gymnosperms' leaves. This tissue is represented by the parenchymatic cells endowed with punctuations (fig. 3C).

In contrast to the previous level, in the upper third of the young leaf, the epidermal and hypodermal cells have more thickened and lignified walls. In addition, a great number of mesophyll cells show deep septums (fig. 4A).

The secretory cells of the three resinifer-

ous canals are surrounded by schlerenchyma cells with thick, lignified walls (fig. 4B).

Regarding the cross sections performed in the mature leaves of *Pinus cembra* L., there are differences between the superior and inferior levels (fig. 5A, 5C). In the inferior level, there are only two resiniferous canals (fig. 5A); the assimilatory parenchyma with characteristic ridge-like invagination into the cells lacks (fig. 5B). The cross-section in the middle level is similar to that of a young leaf (fig. 6A, 6B).

Toma *et al.* (7) showed the similarities and differences between the species of the same subgenus in a comparative histo-anatomical study on the leaves collected from different pine species, in different locations (Ceahlau Mountains, Calimani Mountains, *Anastasie Fatu* Botanical Garden Iasi). The triangular shape, the presence of a single vascular bundle and two resiniferous canals are characteristic for

Strobus subgenus. The number of resiniferous canals varies from a species to another. Thus, the lowest number of secretory canals (two) is found in the leaves of *Pinus monticola* Dougl., *Pinus strobus* L., *Pinus ponderosa* Dougl. ex Laws. In addition, *Pinus nigra* J.F. Arnold and *Pinus sylvestris* L. have the highest number (between eight and twelve) of secretory canals.

Antioxidant enzyme activities

The activity of antioxidant enzymatic systems was studied in samples collected from two different locations (Vatra Dornei - VD and Calimani Mountains - CM). In the samples collected from Calimani Mountains, SOD activities were almost similar (224.86 ± 15.38 U/mg protein in leaves and 230.97 ± 33.52 U/mg protein in the long shoots). The highest SOD activity (344.90 ± 12.89 U/mg protein) was determined in the long shoots collected in Vatra Dornei (tab. I).

POD activity varied significantly, especially in the leaves. In CM samples, the activity was almost six times higher than the one in VD leaves (7611.11 ± 53.57 in comparison to 1411.49 ± 7.07 U/mg protein). CAT activity was not detectable showing that hydrogen peroxide produced in *Pinus cembra* L. is not decomposed by catalase pathway.

TABLE I

Superoxide dismutase and peroxidase activity in *Pinus cembra* L. leaves and long shoots

	SOD activity U/mg protein±SD	**POD activity U/mg protein±SD**
VD leaves	206.03 ± 7.28	1411.49 ± 7.07
VD long shoots	344.90 ± 12.89	3384.99 ± 24.39
CM leaves	224.86 ± 15.38	7611.11 ± 53.57
CM long shoots	230.97 ± 33.52	3228.77 ± 4.94

VD-collected in Vatra Dornei; **CM**-collected in Calimani Mountains

There is no correlation between SOD and POD activities cembran pine samples. There are many studies concerning the metabolism of hydrogen peroxide in plant cells, in normal and also in stress conditions. For example, the overproduction of hydrogen peroxide in chloroplasts is related to excess light stress. This finding can explain the high level of POD activity determined in CM leaves. Hydrogen peroxide can also accumulate by other mechanisms. Hydrogen peroxide can also be generated by some oxidases that release hydrogen peroxide after oxidation of their substrates. Literature data also mentions that oxidative stress in polluted regions causes an increase of SOD and POD levels in pine needles (8).

Studies on *Pinus halepensis* Mill. showed that Cu/Zn-SOD isoform had a low activity in the full-grown leaves exposed to ozone. The authors suggested that it is possible to correlate these results with the lack of involvement of SOD isoform in the defence mechanisms against ozone-induced stress. The study showed a decrease in Cu/Zn-SOD activity in the full-grown leaves in comparison to the young leaves. This result was attributed to the premature leaf senescence as a response to environmental stress factors (9).

Regarding the environmental pollution, SOD activity was increased in *Pinus sylvestris* L. samples next to industrial areas

(a phosphate fertilizer factory and a copper foundry) in comparison to samples collected from unpolluted areas (8). This finding shows the impact of environmental pollution on the level and activity of plant cell antioxidants. In our study, the cembran pine leaves and long shoots were collected from an area next to a former sulphur quarry in the Calimani Mountains. The green belt of pines made the transition between the mining area and the alpine vegetation. It is possible that, besides other stress factors (low temperatures, increased light and abundant snow), the pollution generated by the sulphur quarry affected the stress enzyme activities. Although the sulphur quarry was closed in 1997, the environmental works have not been finished yet.

CAT, an enzyme involved in the photorespiratory mechanisms, showed no activity in all cembran pine samples. This lack of activity may suggest that the enzyme does not play a key role in antioxidant protection of *Pinus cembra* L.. Intense light exposure led to catalase photoinactivation.

Higher POD activity in samples from Calimani Mountains can also be explained by the exposure to UV-B radiations. Literature data show that this exposure can be correlated with an increase in flavonoid content and antioxidant enzyme activities, SOD and POD having a key role in the prevention of photooxidative damage (8, 9).

Heavy metal contents

The contents of Zn, Cu, Pb and Cd in the leaves and long shoots of cembran pine are shown in tab. II.

TABLE II

Zn, Cu, Pb and Cd levels in *Pinus cembra* L. leaves and long shoots

Samples	Level (µg/g dry weight)			
	Cd	**Pb**	**Zn**	**Cu**
VD leaves	< 0.32	< 1.5	83	15.78
VD long shoots	< 0.32	3	62.8	17.11
CM leaves	< 0.32	< 1.5	92.9	13.84
CM long shoots	< 0.32	2.86	75.6	19.1

Cd quantification limit = 0.32 µg/g, Pb quantification limit = 1.5 µg/g;.
Zn quantification limit = 0.74 µg/g; Cu quantification limit = 0.07 µg/g.
VD-collected in Vatra Dornei; **CM**-collected in Calimani Mountains

Studies concerning the influence of heavy metals on the plant development showed that plant exposure to high concentrations of Cd affected photosynthesis, transpiration and stomatal opening mechanisms, inhibited different enzymes, induced root browning and decreased plasma membrane permeability. Cd is a non-essential metal for plant growth (10). For all cembran pine samples, Cd concentration was lower than the quantification limit (< 0.32 µg/g) suggesting that Cd is found only as traces in the cells and does not affect the plant life cycle.

Pb, the most spread toxic metal in soil, alters membrane permeability in plants, induces and increases ROS generation. Generally, in plants, the highest Pb concentration is found in roots, but significant quantities may be transported to all other plant parts. Pb can also be absorbed from the atmosphere. In the lignified tissues, the concentration seems to be more important than in the non-lignified ones. In cembran

pine samples, Pb levels were lower than the quantification limit in leaves, but two times higher than the quantification limit in the long shoots (3 µg/g in VD samples and 2.86 µg/g in CM samples). This result may be associated with a slight increase in SOD activity in the long shoots in comparison to the leaves. Other studies reported an increase in POD activity proportional to Pb content (11).

Zn is considered an important micronutrient for plant development. Zn is used by plants in many metabolic pathways such as chlorophyll synthesis. Zn is also vital for the activity of more than 300 enzymes (dehydrogenases, isomerases, peptidases, polymerases, superoxide dismutase, anhydrase, aldolase, enolase). Zn excess generates phytotoxicity. The main effects of Zn accumulation are delays in growth and development, chlorosis in the young leaves and alteration of physiological processes. An increase in Zn concentration can lead to Mn and Cu deficiency in plant branches. Our results showed high Zn levels and lower Cu levels in all samples. Literature reports that a content of 30 to 100 µg Zn/g of dried plant material is sufficient to support adequate plant growth (12). Our research showed a concentration between 62.8 and 92.9 µg Zn/g in all samples which suggests that Zn was not a stress factor in the samples tested in our study.

Cu is also known as a micronutrient for plant development. It is an important component for different biological constituents such as proteins. It also contributes to carbon dioxide assimilation and ATP synthesis. Increased Cu levels lead to cytotoxicity and oxidative stress. Baker and Senef (3) concluded that the average content of Cu in plant tissue is 10 µg/g dry weight. Values below and over this limit generate plant disorders. Our study determined Cu concentrations between 13.84 and 19.1 µg/g dry weight which are higher in comparison to the normal values.

CONCLUSIONS

In our study, the histo-anatomical cross sections revealed specific elements of *Strobus* subgenus, *Pinus cembra* L. belongs to: a triangular shape of leaf cross section, one single vascular bundle and two resiniferous canals in the mature leaf (in the inferior and superior level, respectively). The values determined for the antioxidant enzyme activities correlated with those obtained for the heavy metal contents suggest the importance of SOD and POD for the protection of this species against different biotic and abiotic stress factors.

ACKNOWLEDGEMENTS

The authors express their gratitude to Acad. Prof. Dr. Constantin Toma (University „Alexandru Ioan Cuza" of Iasi, Faculty of Biology) and to the Administrative Staff of the Calimani National Park for their support in the acquisition of the plant material.

ANTICANCER COMPOUND ISOLATED FROM SEEDS OF *MAESA LANCEOLATA*

Maesa lanceolata (*Myrsinaceae* family) is an ethno-medicinal shrub growing in countries in Central Africa, especially in Ethiopia and Kenya, where it has been used against bacterial and viral infections but also in the treatment of rheumatic arthritis. Studies performed to date on *M. lanceolata* concentrated on saponins which showed the capacity to affect angiogenesis, flavonol glycosides and alkylated benzoquinones. Present studies focus on identifying anti-cancer agents in the seeds. The methanolic extract obtained from seeds of *M. lanceolata* was fractionated with *n*-hexane, chloroform, ethyl-acetate, *n*-butanol and water. Based on the results of activity-guided assay, the ethyl acetate fraction showed the highest biological activity and was selected for further analysis. Preparative HPLC led to the isolation of quercetin-3-O-rhamnoside (quercitrin). The compound was tested for anti-tumor activity on HCT116 human colon cancer cells: it decreased cell viability in a dose-dependent manner. Moreover, in a long-term survival clonogenic assay, quercitrin determined dose-dependent inhibition of the colony-forming activity of HCT116 cells. Its GI_{50} (50% growth inhibition) value was 72.3 μM, suggesting that the compound has intrinsic antitumor activity (Shin SI, Dekebo A, Terfa A et al. Identification of an anticancer compound contained in seeds of *Maesa lanceolata*, a medicinal plant in Ethiopia. *J Korean Soc Appl Biol Chem* 2014; 57(4): 519−522).

ASSESSMENT OF THE CONSEQUENCES IN PREMATURE LOSS OF THE TEMPORARY LOWER MOLARS

Ana Petcu, Adriana Bălan, Laura Maria Vasilca Gavrilă, Carmen Savin
University of Medicine and Pharmacy "Grigore T. Popa" - Iaşi
Faculty of Dental Medicine
Department of Pedodontics

ASSESSING OF THE CONSEQUENCES IN PREMATURE LOSS OF THE PRIMARY LOWER MOLARS (Abstract): The consequences of premature loss of temporary teeth are complex, both of functional and morphological order and the clinical presentation depends on multiple factors: the temporary tooth loss rate as compared with permanent tooth eruption sequence and the number and topography of teeth extracted, so the clinical form of edentulous, which can be frontal or lateral, symmetric or asymmetric, isolated or continuous. **Keywords:** PREMATURE LOSS, TEMPORARY MOLAR, D+E SPACE, SPACE MAINTAINER.

From all the assessment and monitoring methods of the consequences of premature loss of deciduous molars, examining the casts remains an additional examination of undeniable value, providing an overview of the addressed issues and especially of the therapeutic solutions that can be applied.

Popovich and Thompson argued that premature loss of temporary molars may result in reducing the length of the arch, which in turn will cause crowding, rotations and will influence the harmonious alignment of the permanent dentition (1).

Regarding the premature loss of temporary molars, evaluating of the consequences that can appear and how it can intervene therapeutically may be crucial to prevent permanent damage to dentition.

MATERIAL AND METHODS

The study group was constituted by the selection of 50 models of child patients, between 6 and 10 years old, which were presented in the Pediatric Dentistry Clinic of Iasi in period May 2010 - September 2013, with diverse diagnosed pathologies.

Among them, the control group consisted of 6 children who did not have any temporary molar loss, the remaining 44 children represents the study group with loss of one or more temporary molars in the mandibular arch. Measurement and interpretation of the casts was performed by a single physician.

Interpretation of the casts involved evaluating and measuring the following data:

- recording molars lost prematurely and proximal caries in the molars present on the lower arch;
- extractional space, arch width, arch length, arch perimeter, distance between the canines.

The database was created using MS Excel software and statistical analysis was performed in *SPSS 16.0.* We first applied the Kolmogorov - Smirnov normality test

to see which of the variables that we will continue to analyze normal and do not respect the law - to decide what significance tests will still apply. Finally, tests were used for statistical interpretation: Levene test for equality of opportunity, equality t test environments, nonparametric Mann -Whitney test, ANOVA and Pearson correlation coefficient.

RESULTS

As a first step of statistical processing we assessed whether the length, width, perimeter and distance between the canines lower arch decrease in children with premature loss of temporary lower molars. Lower arch width ranged from cases without premature loss of temporary molars between 40.57 and 46.22 mm, and in cases of premature loss of temporary molars between 42.65 and 44.45 mm. Lower arch length ranged from cases without premature loss of temporary molars between 24.53 and 27.00 mm, and in cases of premature loss of temporary molars between 24.96 and 27.27 mm. Arch perimeter ranged from cases without premature loss of temporary molars between 69.17 and 73.76 mm, and in cases of premature loss of temporary molars between 24.74 and 26.29 mm.

In the third quadrant, the space D without loss of temporary molars varied between 7.43 and 7.84 mm, the average being 7.64 mm, while in the cases with loss of first temporary molars varied between 5.12 and 8.21 mm, average being 6.66 mm. Space is varied in the cases without second molar temporary loss between 8.98 and 9.82 mm, average being 9.40 mm, while in cases with temporary second molar loss it ranged between 4.49 and 7.76 mm, average of 6.13 mm. Area D + E in the cases without loss of temporary molars ranged between 16.06 and 17.51 mm, with an average of 16.79 mm (standard deviation = 1.94066), while in cases with loss of both temporary molars, it ranged between 13.56 and 16.63 mm, with an average of 15.10 mm (standard deviation = 1.83848).

Applying non-parametric Mann - Whitney test showed that there was a statistically significant difference in cases with loss of temporary molar of space D (p = 0.047) and in cases of temporary second molar loss of space E (p = 0.042) (tab. I).

TABLE I

Mann -Whitney test (quadrant III – premature loss of first temporary molar / second temporary molar - region D + E)

	C III – Premature loss	N	Average rank	Some of ranks	Statistic	Value
C III - Space D	no	29	19.48	565.00	Mann-Whitney U	44.000
	m I	6	10.83	65.00	Wilcoxon W	65.000
					Z	-1.991
	Total	35			Semnif. asimpt. p	.047, SS
C III - Space D	no	29	16.59	481.00	Mann-Whitney U	46.000
	m II	6	24.83	149.00	Wilcoxon W	481.000
					Z	-2.035
	Total	35			Semnif. asimpt. p	.042, SS

T test for equality of averages showed a statistical significance in the comparison of the space E and that D + E in cases of temporary second molar loss (p=0.000, p= 0.005) (tab. II)

In the quadrant IV, the space D without loss of first temporary molar varied between 7.47 and 7.94 mm, the average being 7.71 mm, while in the cases with loss of first temporary molar varied between 4.44 and 8.55 mm, average being 6.50 mm. Space E is varied in cases without second molar temporary loss between 9.00 and 9.92 mm, averaging 9.46 mm , while in cases of second temporary molar loss it ranged between 5.53 and 6.77 mm, average being 6.05 mm. Area D + E in cases without loss ranged between 15.22 and 17.94 mm, an average of 16.58 mm (standard deviation = 3.57239), while in cases with loss of both temporary molars, it ranged between 13.12 and 17.20 mm, with an average of 15.16 mm (standard deviation = 1.94079).

TABLE II

Independent Samples Test (quadrant III - Area D + E – premature loss of second temporary molar)

		Levene test equality of variants		T test for equality of averages						
		F	Sig.	t	df	Semnif. P	The average difference	Std error difference	95 % confidence interval for the difference	
									Lower limit	Upper limit
C III - Space E	equal variances	.840	.366, NS	6.090	34	.000, SS	3.27333	.53749	2.18102	4.36564
	unequal variances			4.896	6.095	.003	3.27333	.66854	1.64360	4.90307
C III - SpaceD+ E	equal variances	.026	.872, NS	3.026	34	.005, SS	2.57667	.85139	.84643	4.30690
	unequal variances			3.347	7.951	.010	2.57667	.76973	.79976	4.35358

Nonparametric Mann -Whitney test showed that there was a statistically significant difference in cases of first temporary molar loss of the space D (p = 0.024) and in cases of second temporary molar loss of the space E (p = 0.000).

T test for equality of averages showed a statistical significance in the comparison of the space D + E and temporary second molar loss cases (p = 0.034) (tab. III)

In the quadrant III, D space where no decay on temporary molars approximated varied between 7.17 and 7.79 mm, an average of 7.48 mm, while in case of the presence of proximal caries it ranged between 7.12 and 8.07 mm, averaging 7.60 mm. E space is varied in cases without proximal caries in the molars between 8.27 and 9.62 mm, averaging 8.95 mm, while in cases with presence of proximal caries it ranged between 8.65 and 9.87 mm, averaging 9.26 mm. Levene test of equality of variants showed a significant difference statistically between the amount of space is where the temporary molars with proximal cavities and where they were present (p=0.027) (tab. IV).

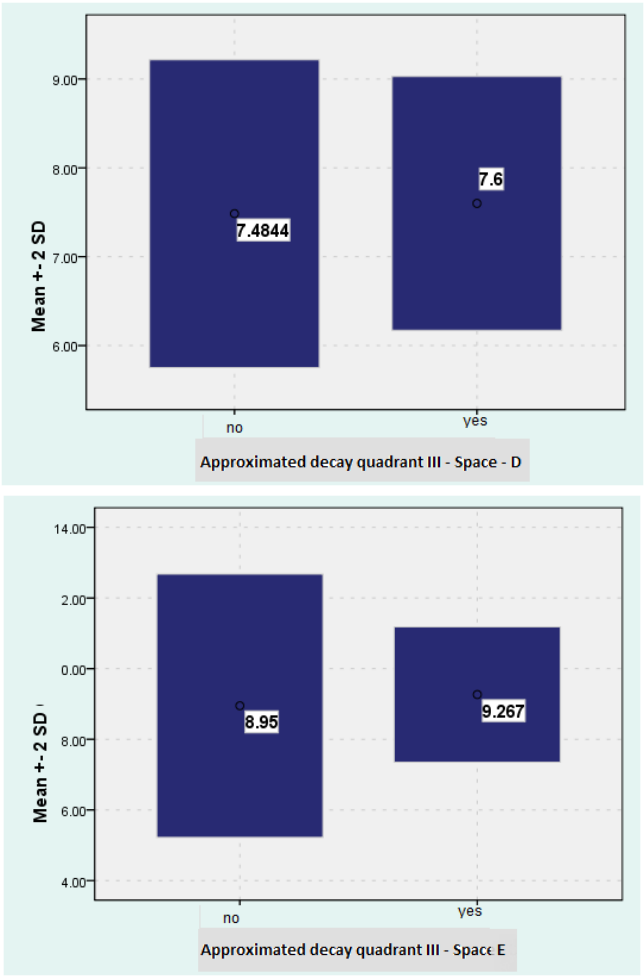

Fig. 3. Changes in spatial dimensions D and E in quadrant III

In the quadrant IV, the space D in cases without tooth proximal loss varied between 7.39 and 8.01 mm, the average being 7.70 mm, while in case of the presence of prox-

imal caries it ranged between 6.96 and 7.78 mm, averaging 7.37. Space E is varied in cases without proximal caries in temporary molars between 7.85 and 9.34 mm, averaging 8.60 mm, while in cases with presence of proximal caries it ranged between 8.38 and 10, 19 mm, averaging 9.29 mm.

Nonparametric Mann -Whitney test showed no statistically significant difference between cases with and without the presence of proximal tooth decay of temporary molars on the size of the space E, instead showed a statistically significant difference for the space D (p = 0.027) .

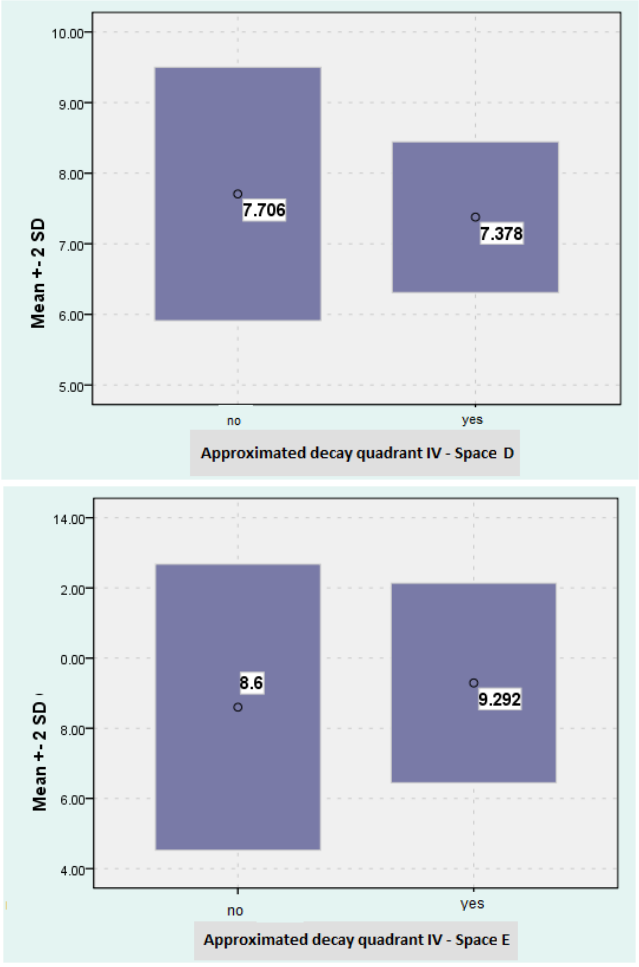

Fig. 4 .Changes in spatial dimensions D and E in quadrant IV

DISCUSSION

The research of space changes in dental and alveolar arches is difficult to accurately due to multifactorial variants that influence the results. Among the factors that influence these evaluations are: age in moment of temporary molar premature loss, facial and dental growth potential, occlusion status, vicious habits and study methodology. Another factor related to the patient was the

time while since the premature loss. Largest amount of space loss was observed within 6 months of tooth loss (Beierl & Hune, Stratford, and Wright & Kennedy) (2).

Our study showed that impaired molars with proximal cavities in the mandible determine a statistically significant reduction of leeway space. Cavities located on mesial face of second temporary molar have largest impact. Proximal caries and their sequelae are considered potential factors in creating changes in occlusal relationship (Pedersen et al., 1978) (3). Helm and Ronnerman have shown that in particular the cavities of the lower jaw have a great effect on crowding. Crowding distribution in mixed dentition occupies a greater percentage at the children affected by caries (4, 5).

In this study, statistical processing of data showed a statistically significant difference in cases of premature loss of first temporary molar on space D and in cases of premature loss of temporary second molar on the space E. Loss of two temporary molars appear to cause a decrease in space greater than the loss of only one temporary molar. The loss of area was significantly higher on mandible than in the maxillary jaw. These results are comparable to those reported in the literature (6).

The Northway et al. studied the effects of premature loss of temporarily teeth upon 107 children and they have shown that at the lower jaw was observed a severe reduction of space of 3,7mm in association with the premature loss of second temporary molar compare to the control group (7).On a group of 104 children, Ronnerman & Thilander found that children with early loss of temporary molars showed significantly less space in both jaws relative to the control group. Seipel compared the loss of space on the extraction side in 50 cases with another side, where there is not extraction. The average difference between these two sites was 1.9 ± 0.3 mm, with the majority of cases, about 70 %, less than 3 mm. Kronfeld found that 51 % of first temporary molars lost prematurely and 70% of second temporary molars lost prematurely have resulting a loss of space and consequent tooth malposition of succession of permanent tooth.

Our study revealed that premature second temporary molar extraction causes a greater reduction of leeway space than premature first temporary molar extraction, leading to the idea that premature loss of deciduous second molar is expected to have a more pronounced effect on malocclusions with crowding in the permanent dentition, because medium and great crowding cannot be solved on the basis of drift space of Nance. The mandibular arch, premature loss of first deciduous molar active during active eruption of first permanent molar can cause migration to mesial both temporary second molar and first permanent molar. Similarly, if second temporary molar fall off prematurely, mandibular arch length is reduced so that that the normal leeway space will reduce and crowding will occur (8).

Our results confirm studies by Helm, Owen, Lin and Li - Ching (9). In premature loss of first temporary lower molar, our results are consistent with those of Lin, who showed that the space D + E on the extraction side to 6 months after extraction was $15,62\text{mm} \pm 1,13\text{mm}$ significantly lower than in the control space, 16.88 ± 1.12mm.

A space maintainer is appropriate to prevent loss of space; however, it can also increase carious susceptibility due to poor oral hygiene and causes discomfort to long-

term use. Also, the failure of a space maintainer can cause parents to question the effectiveness and cost between such devices. The decision to use space maintainers should be based on good judgment and knowledge of the principles of oro-facial development and growth (10, 11).

CONCLUSIONS

Premature loss of temporary molars in mixed dentition caused a loss of space statistically significant in the lower arch.

Early space changes after premature loss of temporary molars is realized by moving to temporary canine distal to extraction space and especially by moving of second temporary and first permanent molar to the mesial.

There are changes significant statistically upon arch width, arch length and arch perimeter after premature loss of second deciduous molars.

This study shows the need for a space maintainer in the circumstances of premature loss of temporary molars to prevent loss of space and crowding.

SCREENING OF ANTIBACTERIAL EFFECTS OF ANISE ESSENTIAL OIL ALONE AND IN COMBINATION WITH CONVENTIONAL ANTIBIOTICS AGAINST *STREPTOCOCCUS PNEUMONIAE* CLINICAL ISOLATES (Abstract): **Aim**: This study aimed to investigate the effects of anise essential oil alone and in combination with conventional antibiotics (amoxicillin, ciprofloxacin) against *Streptococcus pneumoniae* clinical isolates. **Material and methods**: Anise essential oil (AEO) was isolated by hydrodistillation from dried powdered fruits. Its chemical composition was investigated by GC-MS and GC-FID. Broth dilution assay was used to evaluate the antibacterial effects of anise essential oil. The interactions with antibiotics were studied by the checkerboard assay. **Results**: *Trans*-anethole (90.18%) was identified as major constituent in anise essential oil. Almost all combinations AEO-amoxicillin and AEO-ciprofloxacin showed indifferent interactions ($1 < \text{FIC index} \leq 2$). Positive interactions (addition and weak synergism) were found only for four combinations AEO-amoxicillin (FIC index=1, 0.62, 0.75 and 0.5) and one combination AEO-ciprofloxacin (FIC index=0.62). **Conclusions**: Herbal products containing anise essential oil may be used as expectorants in combination with amoxicillin or ciprofloxacin in *Streptococcus pneumoniae* infections without diminishing antibiotic efficacy. **Keywords**: *PIMPINELLA ANISUM* L., AMOXICILLIN, CIPROFLOXACIN, *STREPTOCOCCUS PNEUMONIAE* CLINICAL ISOLATES.

Pimpinella anisum L. (Apiaceae, anise) is an herbaceous annual plant native to the eastern Mediterranean region and western Asia. The fruit, also called aniseed, has a sweet, aromatic taste and a characteristic flavor due to a high content of essential oil (1.5-5%) containing *trans*-anethole as major constituent (80-90%). The fruits have been used to flavor foods and alcoholic beverages since Ancient times. Nowadays both the anise fruits and anise essential oil are used as carminative, galactagogue, spasmolytic and expectorant agents. Crushed or powdered dried fruits, alone or in combination with other herbal drugs and herbal products containing anise essential oil are recommended for their expectorant properties in lower respiratory tract infec-

tions. The efficacy is mainly due to *trans*-anethole. *Trans*-anethole activates the ciliary movements in the bronchial epithelium thus facilitating the removal of bronchial secretions (1-3). In addition, both *trans*-anethole and anise essential oil showed antimicrobial effects against different pathogens responsible for lower respiratory tract infections. Anethole was found to be effective against *Escherichia coli* 35218 (MIC = 16 μg/mL), *Pseudomonas aeruginosa* ATCC 10145 (MIC=4 μg/mL), *Klebsiella pneumoniae* RSKK 574 (MIC=8 μg/mL) and *Staphylococcus aureus* ATCC 25923 (MIC=4 μg/mL). *Escherichia coli* and *Klebsiella pneumoniae* isolates with extended spectrum β-lactamase (MIC=64 and 128 μg/mL, respectively), gentamicin-resistant *Pseudomonas aeruginosa* isolate (MIC=64 μg/mL), methicillin-resistant *Staphylococcus aureus* isolate (MIC>128 μg/mL) had a lower susceptibility to anethole (4). Anise essential oil showed antibacterial activity against *Escherichia coli* (MIC=0.5% v/v) and *Staphylococcus aureus* (MIC=0.25% v/v) (1). The efficacy of anise essential oil against isolates of lower respiratory tract infections has been poorly investigated. A literature survey revealed only one study reporting a weak activity of anise essential oil against methicillin resistant *Staphylococcus aureus* isolates: 10 μL of anise essential oil developed inhibition zones of 8-11 mm (5). Possible interactions between anise essential oil and conventional antibiotics against pathogens responsible for lower respiratory tract infections have not been investigated yet.

Penicillin-resistant *Streptococcus pneumoniae* is the major pathogen leading to community acquired infections including pneumonia (6). Amoxicillin is a first-choice antibiotic in lower respiratory tract infections. Ciprofloxacin is also an important treatment option; it has a good antibacterial activity against most of the respiratory pathogens and a high penetration rate into the bronchial tissue (7, 8). As anise preparations are often recommended in lower respiratory tract infections, the aim of the present study was to investigate possible interactions between anise essential oil and conventional antibiotics (amoxicillin, ciprofloxacin) against *Streptococcus pneumoniae* clinical isolates.

MATERIAL AND METHODS

Chemicals. Alkane standard solution C_8-C_{20} and dimethylsulphoxide (DMSO) were purchased from Sigma-Aldrich (Steinhem, Germany). Mueller Hinton agar and broth were obtained from Biolab Zrt. (Budapest, Hungary). Lysed horse blood was from Oxoid (Basingstoke, UK).

Plant material. Dried anise fruits were purchased from a local supermarket and were identified in the Discipline of Pharmacognosy, Faculty of Pharmacy, University of Medicine and Pharmacy "Grigore T. Popa"-Iasi where a voucher specimen has been deposited.

Bacterial isolates. Several *Streptococcus pneumoniae* clinical isolates (*S. pneumoniae* 4409; *S. pneumoniae* 4546 and 4566–resistant to penicillin; *S. pneumoniae* 4423 and 4723 – resistant to penicillin, streptomycin and erythromycin) were obtained from the Culture Collection of the Microbiology Laboratory, Lung Clinical Hospital, Iasi.

Essential oil isolation. The powdered dried fruits were hydrodistilled for 3 h in a Clevenger type apparatus. Anise essential oil (AEO) was dried over anhydrous sodium sulphate and stored in a sealed glass tube at 4°C until analysis.

Gas-chromatography analysis. GC-FID analysis of AEO was carried out on an Agilent 6890 gas-chromatograph equipped with a flame ionization detector and a DB-5MS capillary column (30 m × 0.25 mm internal diameter, 0.25 μm film thickness). A volume of 0.3 μL of AEO was injected in the split mode (split ratio 1:30). Helium was used as carrier gas at a flow rate of 1.5 mL/min. The injector and detector temperatures were maintained at 250°C. The analysis was performed using the following temperature program: 3°C/min from 40 to 250°C, 4 min at 250°C, 10°C/min from 250 to 280°C, 2 min at 280°C. GC-MS analysis was carried out on an Agilent type 7890A gas-cromatograph equipped with an Agilent 5975C inert mass selective detector with electron impact ionization. The column and GC-MS conditions were the same as the ones described in GC-FID analysis. The MS source and quadrupole temperatures were set at 230 and 150°C, respectively. Mass spectra were acquired in the scan mode (mass range 15–450 *m*/*z*) (9). The retention indices were determined by analysing a standard solution of *n*-alkanes (C_8–C_{20}) under the same chromatographic conditions. The compounds were identified by comparing their recorded mass spectra with those stored in the GC-MS database (Wiley 275 mass spectral library) and with those of pure standards. In addition, the retention indices relative to *n*-alkanes were compared with those mentioned in literature and with those of pure standards (10, 11). The relative percentages of the essential oil constituents were obtained from the FID peak areas without using correction factors.

Broth dilution assay. The minimum inhibitory concentration (MIC) values were assessed by a broth dilution assay (12). A 200 mg/mL stock solution of AEO was prepared in a mixture of ultrapure water and DMSO. Serial two-fold dilutions of AEO, ranging from 100 to 0.05 mg/mL, were prepared in Mueller Hinton broth supplemented with 5% (v/v) lysed horse blood. Amoxicillin and ciprofloxacin were used as positive controls in dilutions ranging from 16 to 0.007 and 8 to 0.003 μg/mL, respectively. 10 μL of *inoculum*, adjusted to 0.5 McFarland turbidity standard (10^5 UFC/mL), were dispensed in 0.5 mL dilution. Negative controls (bacterial growth control, sterility control, solvents used to dilute AEO and antibiotics) were also included in the assay. The incubation was performed at 37°C for 24 h. The experiment was carried out in triplicate. Minimum inhibitory concentration (MIC) was defined as the lowest concentration of sample that completely inhibited the visible growth of tested microorganisms.

Checkerboard assay. The checkerboard method was performed to evaluate the effects of the combinations AEO-antibiotics (12, 13). Twelve serial two-fold dilutions of AEO and antibiotics were prepared using the same procedure as described for assessment of MIC values and dispensed into 96-well plates in a checkerboard manner: AEO (50 μL) was diluted two-fold along the X-axis while the antibiotic (50 μL) was diluted two-fold along the Y axis. The *inoculum* (5 μL), adjusted to 0.5 McFarland standard of bacterial concentration, was added into each well of the plate. The plates were incubated at 37°C for 24 h. The experiment was performed in triplicate. The interaction of AEO with the antibiotics was interpreted according to the fractional inhibitory concentration index (FIC index) values. FIC index of the combination was determined by the following formula: FIC index = FIC_{AEO} + $FIC_{antibi-}$

$_{otic}$, where: FIC_{AEO} = MIC of AEO in combination/MIC of AEO alone and $FIC_{antibiotic}$ = MIC of antibiotic in combination/MIC of antibiotic alone. An interaction is defined as synergistic if FIC index ≤ 0.5, additive if 0.5 < FIC index ≤ 1, indifferent if 1 < FIC index ≤ 2 and antagonistic if FIC index > 2 (14).

RESULTS AND DISCUSSION

Anise essential oil analysis. The hydrodistillation of anise fruits gave a yellowish essential oil with a yield of 2.63% (v/w). GC-FID and GC-MS analyses of AEO revealed the presence of twelve compounds accounting for 97.34% of the total essential oil. These compounds, in order of their elution on DB-5MS column, their retention indices and percentages are listed in tab. I. *Trans*-anethole (90.18%) was the most abundant.

TABLE I
Chemical composition of anise essential oil

Compound	RI[a]	RI[b]	%
limonene	1022	1024	0.05
γ-terpinene	1050	1054	0.02
estragole	1193	1197	0.75
trans-anethole	1280	1282	90.18
γ-elemene	1335	1335	0.18
anisyl methyl ketone	1376	1380	0.11
α-himachalene	1446	1449	0.41
γ-himachalene	1476	1478	4.60
α-zingiberene	1493	1493	0.49
β-himachalene	1500	1500	0.24
β-bisabolene	1510	1506	0.31
Total			**97.34**
